by pleurisy and fibrosis of the lower lobe of the left lung, and consequent dilatation of the bronchi of that side." Such was Dr. Williams's diagnosis, and he considered that several bronchiectases existed, but that there were three of larger size than the rest, the situations of which he indicated at the posterior part of the left base. On two occasions I endeavoured to open one of these cavities after ascertaining that the pleura was obliterated by adhesions, on the second occasion after excising a portion of rib. At the first operation a small amount of muco-pus had been drawn out by the aspirator; but owing to the slipping of the cannula, which was being used as a guide during a paroxysm of coughing, even this, probably very minute, cavity was not reached, and at the second attempt no cavity of any kind was met with, although the lung was very freely incised, causing considerable hæmoptysis and some hæmorrhage. A drainage-tube was inserted and worn for some time in the hope that the abscess might rupture into the track that had been made. There was at no time, however, any material escape of pus through the wound, and ultimately the tube was withdrawn and healing was allowed to go on. It was complete in about a month after the second operation. The difficulty mentioned above, which is caused by extreme softness of the pleural adhesions, was very marked in this case, and rendered the incision into the lung an uncertain and unsatisfactory procedure. This patient is, and has been for some time, in danger of the septic troubles of which mention was made before, and also of that which may arise from hæmoptysis; and although she herself thinks she has improved since she has been under treatment, I must, to speak honestly, seriously doubt whether much, or any, of this improvement depends upon what has been done surgically. She had a severe attack of hæmoptysis whilst she was wearing the tube, but this of course might have happened independently, for she had similar attacks before. She certainly was exposed to some risk by the mere fact of opening up the cellular tissue for the passage of the putrid pus contained in the bronchi, and a possible risk from the doubt which existed as to the presence of pleural adhesions. In her case the pleura was, in part at least, obliterated, so that the danger hinted at did not arise, but that it is a real one is exemplified by the following very similar case, in which the same course was adopted.

H. C——, a married woman aged twenty-nine, had been the subject of a cough all her life, which was worse during the winter. She was said to have had "bronchitis and pleurisy" in February, 1885, after which time the expectoration had been much more copious, and during the two months before admission (in December, 1885) it had been offensive, and dyspnœa had developed itself. She had had an attack of hæmoptysis. As in the last case, the signs of bronchiectasis were marked in one region, the left base, but not very obvious elsewhere. The disease was advancing and the general condition bad, and it was therefore decided to make an attempt to open and drain the cavity in the left base. An exploratory puncture on Dec. 30th resulted in the extraction of a small quantity of reddish fluid, which evidently came from the pleura, so any further operation was deferred till Feb. 4th, 1886, when a puncture was made in the ninth interspace, which revealed practically nothing, but caused a little hæmoptysis; and afterwards an incision was made over the tenth rib, below the angle of the scapula, and two inches of it were removed. The pleura was not adherent immediately beneath the opening, but a small cavity was entered surrounded by feeble adhesions. A linear incision in the lung opened a small bronchiectatic cavity near the surface of the lung, through which a probe passed readily into a bronchus for a long distance, causing troublesome coughing. The opening was dilated with dressing forceps, and then the finger and afterwards a drainage-tube about two inches long were introduced; but this led to the separation of the lung from the chest walls and the opening up of the anterior part of the pleural cavity, where there were no adhesions. This made it very difficult to dilate the opening in the lung. Very little bleeding occurred, and very little pus escaped, though the patient coughed up a considerable quantity and vomited a good deal which she had swallowed. Here the operation was so far successful that one part of the labyrinthine cavity was reached and drained; but although afterwards a considerable amount of pus escaped through the opening, it made but little difference to the amount of daily expectoration, and for a time her condition gave us very great anxiety; for the opening up of the pleura not only rendered the lung of this side practically

Digitized by Google

useless and vastly increased the dyspnœa, but also gave rise to a septic pleurisy causing grave constitutional disturbance and serious risk to life. She left the hospital in a very weak condition, and is supposed to have died since, but we have not been able to ascertain when or how this happened.

I might multiply the account of such cases, but as this would be tedious, I will only mention in any detail one other, in which no operation was attempted, though, as was shown by the necropsy, it was the only one in the series at present in which any great good was likely to be gained.

J. W——, aged thirty-two, a patient of Dr. Powell's, a plasterer by trade, had inflammation of the lungs seven years before, from which he apparently completely recovered, with the exception that he suffered from a dry hacking cough for a year. Twelve months before admission he had an acute illness, accompanied by a severe cough, with shiverings and dyspnœa, after which he began to expectorate between one and two pints daily, the expectoration being odourless at first, but gradually becoming highly offensive. He is said to have had a left pleurisy six months before admission, which made matters much worse. On admission, in October, 1885, he exhibited very puzzling physical signs: the right side seemed fairly healthy, but on the left side there were at times all the signs of a large cavity in the neighbourhood of the angle of the scapula, while at others these signs were altogether absent. His temperature varied, being sometimes almost normal, sometimes varying between 99° and 103°. It was found that by inverting him a copious flow of expectoration could be obtained, generally accompanied by some marked alteration in the physical signs in the back. So doubtful, however, did the indication appear to be, that the point of recommending surgical interference was never actually reached, and about Nov. 12th his temperature rose, he became rapidly worse, and died on Nov. 16th. At the post-mortem it was found that there were considerable adhesions on both sides, more on the left than the right, and a small localised purulent collection on the right side. The left lung showed remarkably little fibroid thickening, but was studded with bronchiectatic cavities, the largest of which was in the posterior axillary line, the next largest being near the angle of the scapula—in fact, in the position diagnosed. Dr. Kidd, before making the post-mortem, inserted a knife at the point indicated by him during life, and it entered the cavity directly. There was slight but not excessive bronchial dilatation on the right side.

The noticeable point about this case is the very large size of the main cavities. One at least could clearly have been reached by an incision, but it is certain that even this would only have afforded the patient very partial relief, as there were many others in this lung, and a similar condition was starting upon the opposite side, and even the cavity which could be reached was much branched, and probably would not have been very efficiently drained even if it had been fully incised. The condition of the apex of the right lung is very remarkable; there seems to be an interstitial change, not starting from anything caused by retained bronchial secretion.

To sum up the state of opinion at the present time with regard to the whole subject, it may be said—1. Gangrenous cavities should always be sought, and, if possible, opened; and the prognosis, if the operation be successful, is not bad. 2. The same may be said in regard to abscesses caused by the rupture of purulent collections from other parts into the lung, at least as regards the pulmonary complication. 3. Abscesses connected with foreign bodies must be opened, and if the body be not found, it must be remembered that, if of any considerable size, it probably lies pretty near the middle line. If possible, these cases should be treated early by tracheotomy and incision. 4. Bronchiectatic cavities, when single (a very rare condition), will be cured by operation. When multiple (a very common condition), they offer but small chance of relief by our present surgical methods. Still, for the reasons stated, an attempt may be made to open the main one if such is to be found, but only if the pleura has been ascertained to be adherent. 5. Tubercular cavities should only be opened in cases where the cough is harassing and the cavity single. Injections may be used to relieve symptoms, but cannot be expected to be curative.

THE treasurer of the Queen's Hospital, Birmingham, has received from Her Majesty a cheque for £100 in aid of the funds of the institution.

NOTE ON PUNCTURE OF THE ABDOMEN FOR EXTREME FLATULENT DISTENSION IN PUERPERAL CASES.

BY W. O. PRIESTLEY, M.D., LL.D.

I HAVE received from Surgeon-Major Franklin (at present on duty with the Lieut.-Governor of the Punjab) notes of a puerperal case which he attended while at Simla in April last year, and which raises the interesting question as to the propriety and utility of puncturing the colon in cases of extreme abdominal distension after delivery. Surgeon-Major Franklin's patient, whom I had known as a girl, went out to be married in India two or three years ago, and her first labour began on April 8th, 1886. The presentation was natural, but after a long and tedious labour, resulting from inefficient pains, the case had to be terminated by forceps under an anæsthetic, and the perineum was ruptured. Sutures were put in the perineum, and all went well until two days later, when the patient became hysterical, and began to suffer from nausea and vomiting; at the same time the abdomen became much distended. Hypodermic injections of morphia, with the application of turpentine to the abdomen, checked the sickness, and allowed milk and lime-water to be taken for a time. Next day the abdominal distension had enormously increased, there was constant vomiting, some dyspnœa, occasional rigors, and signs of exhaustion.

My correspondent says, the obstetric authorities, Playfair, Barnes, and Ramsbotham, gave him no help as to the way he was to relieve the extreme abdominal distension which was threatening the life of his patient. He had tried all the usual remedies without effect, and so was obliged to act for himself. After consultation with a colleague, Dr. Harris, he punctured the ascending colon with a small trocar. The gas escaped with considerable force, making a whistling noise as it passed through the small cannula. With the aid of pressure the greater part of it was expelled and a binder adjusted. Immediate relief was afforded, vomiting ceased, and only slight nausea remained. She had a good night, and next morning the temperature was normal. This first puncture was made about seventy-two hours after the birth of the child. Forty-eight hours later it was necessary to puncture the colon again, and this was followed, as after the first operation, by immediate relief to all the distressing symptoms. The second operation was followed by the giving of calomel, in doses of one-twelfth of a grain, every half-hour, and continued for about sixty hours, until the bowels acted freely. The temperature rose to 102° after the second puncture, and for ten days the case continued to cause some anxiety, owing to nausea and want of sleep. After this the improvement was steady, and the patient eventually got quite well. There is no record of the temperature during the access of the illness, and nothing is said of pain or subsequent inconvenience from the abdominal punctures.

The practice of tapping the abdomen for dangerous retention of flatus is a well-known remedy in some of the ailments of domestic animals, and more particularly the operation is said to be often practised on sheep when they have "blown themselves," as it is called, by having eaten too largely of a very succulent pasture, or of some herbage which is improper for them. The operation is described in some detail in a recent work of fiction depicting country life, and a farmer is spoken of as skilled in the employment of a perforating tube, the proper use of which is alone capable of saving a whole flock of sheep "blown up" after straying into wrong pasture. There are various records of cases where the intestine has been punctured in the human subject for extreme distension in connexion with obstruction of the bowels or hernia. For example, Wagstaffe mentions a case in the *British Medical Journal* for 1877, and Broadbent another in the same journal for 1879. Further references are to be found in "Neale's Digest"; and Mr. Bryant, in the *Medical Times and Gazette* for 1872, details a case of hernia, with intestinal distension, where punctures were made in the bowel without bad result; there was no escape of the bowel contents, and only a drop of blood. That the proceeding is ordinarily innocuous enough is proved by the fact communicated to me by Dr. Broadbent, that in one patient the bowel was tapped for flatus some-

Digitized by Google

where about twenty-eight times, without bad result. Prof. Foussagrives, in the *Gazette Hebdomadaire* for 1877, says that he has seen intestinal puncture practised by Nélaton, Blache, and Velpeau, and that "it is a sovereign operation in some cases, and not dangerous even where there are multiple punctures." Surgeon-Major Franklin says, in one of his letters to me, that he had some recollection of a suggestion made by Dr. Braxton Hicks concerning tapping a flatulent abdomen in puerperal cases, and Dr. Hicks tells me that, though he had suggested it as applicable under certain circumstances, he has not himself employed it. I may remark that in some forms of illness after delivery there is no doubt grave danger arising from extreme abdominal tympanites. It is even probable that with the decline of other untoward symptoms the mere continued pressure of the distended intestines may so keep up irritation of the stomach and depress the heart's action as to become itself a source of peril. In these cases puncturing the intestine where it is most distended may afford notable relief, and experience seems to teach that it may be practised with impunity.

Hertford-street, Mayfair, W.

THE PLACE OF HEALTH IN EVOLUTION.[1]

BY W. R. MACDERMOTT, M.B. DUB.

SOMEONE once, on asking a little negro girl in Kentucky who made her, got for answer, "Nobody made me; I growed." If I asked how we came by our health, a like answer might be given. It might be said that nobody made our health; that we did not make it ourselves; that it came as a gift of nature. If ill-health afflicts us, it would be said that it, too, comes as part of our natural lot. Health and nature here are terms of loose meaning. Health may be taken as a state of being, as a relation of condition, as a formative process. We will take it here as a state of being, made in the sense that it is the outcome of antecedent condition. We take it as expressing a state of being continuous with prior states of the same kind, and shall consider whether variation from current normal condition stands in relation to variation from prior condition.

An idea of fitness comes as an introduction to our subject it is more, however—it is the beginning, middle, and end of it. We usually think of fitness as something qualifying a man beforehand for health, but it is, in fact, a synonym for health. It is not a mere rhetorical phrase, but a term expressing physical truth. Fitness means health in the physical sense; the strong man who wants fitness for health has, in reality, want of health. Health, in truth, means the fitness of states of being to the conditions of life. It is, therefore, as these conditions are unstable, a thing not fixed, but changeable. In the world, as it exists, we find life fitted to many different conditions. Man himself we find fitted to many climates, to lofty mountains and tropical swamps. But as his fitness to one set of conditions so usually is his unfitness to the opposite set. The fitness of the negro to tropic heat means unfitness to a cold climate. The fitness of the European to temperate conditions means unfitness to the extremes experienced elsewhere. We have thus many different states of being, each of which is health only as corresponding to certain conditions. In the end fitness comes to be expressed as structure, and particular modes of structure-growth. The outcome of the fitness of the negro to heat is a mode of structure; his body becomes physically moulded to the condition. On the other hand, the condition is necessary to maintain the fitness. In the northern States of America the negroes are very sickly, one out of every six born in these States being deaf, dumb, blind, idiot, insane, pauper, or in prison. Europeans in hot countries show a like inability to conform easily to the condition of climate. We thus find that a mode of structure once formed subsists for a long time in a race, becoming under unfitting condition a source of ill-health. The fitness to condition means perhaps, in proportion to its completeness, a want of power of accommodation to change of condition. The very fitness of the negro to heat makes it the harder for him to fit himself to cold. When, therefore, we have a people of mixed descent, such descent will bring into it many states, varying from fitness to unfitness, in reference to its conditions of existence. Is this composite state represented in the actual health of the people? In the first place, all modern societies of any importance are extremely composite by descent. They contain elements representing every different condition to which man has fitted himself from time to time. We are so accustomed to the idea of our descent from one man that we do not easily heed the more immediate fact of our descent from mankind *en masse*. Each man has a father and mother, probably brothers and sisters. He will have four grandparents, eight great-grandparents, and so on going backwards. At the tenth generation backwards he may have theoretically 1024 direct ancestors; at the twentieth only 1,048,576, and a corresponding number of collateral relatives. He will not, of course, have so many, but still he must have a vast number. When we remember that twenty, or even a hundred generations cover but a short period in our race history, and that such history records incessant movements of population, we can easily believe that each one of us has built into his constitution part of the negro's state of fitness to heat, part of the Laplander's to cold, part of every state to which man's body has been moulded; it may be said, blended into a sweet and reasonable mean. Yes, but not indissolubly, not perfectly. In Europeans we constantly find characters of skull and feature—of structure belonging to remote and perhaps extinct races. We find the negro Tartar and Malay structural type showing often amongst us more or less distinctly. In idiots and the insane I have seen structural character which I could assign to no race I knew, but which I felt sure belonged to facts of race structure, most likely of remote antique nature. Now, these types are exhibited in a peculiar way. They show in single members of a family as a manifestation of something underlying in latent or dormant form the whole connexion. I have seen the Tartar type in single individuals standing in the relation of third or fourth cousins, the rest of the connexion being Caucasian in appearance. I have seen the negro type assert itself in just the same way. We have here two significant facts—the fact of latency and the fact of exceptional manifestation of structural character; both we must admit, though we fail as a rule to find adequate explanation for them. We know them as unexplained facts of inheritance. They mean that variations of structure corresponding to man's experiences of condition subsist potentially in him and exhibit themselves exceptionally under circumstances for the most part unknown to us.

Let us now ask ourselves what is the sum of the variations of structure thus represented in inheritance. We can see easily enough that we may find in ourselves all, or nearly all, the states which man experiences locally or has experienced historically as man. We can see, too, that many of these states, coming back out of place, out of time, as characters of race structure do, would appear in him as states of unfitness, of ill-health. When, however, the history of the bodily man has to be taken as going back continuously into pre-human experiences, the question arises whether abnormal variations of structure and mode of structure-growth do not also express those experiences. Taking structure generally in relation to both antecedent and current circumstance, we find that change is always not to something new, but to something which exists in some other place or has existed at some other time. When an organ or part of the body exhibits an unfitting pattern, such pattern exists normally somewhere else in the body, or did exist in it at some other time. So far this explains something usually seen in states of ill-health. But the normal pattern itself, which we suppose to change, is a thing determined in inheritance; it is but one of a series of patterns occurring therein. The items in the series, again, are continuous; they not only pass continuously from one into another, but they inhere in a general programme. Thus the great fact of the mammalian pattern in man is determined in inheritance, and is a result in a programme or pattern, not of structure, but of change of structure containing pre-mammalian patterns as items. But this fact conditions the actual pattern; it cannot be taken apart from its determined mode of formation, which always remains represented in it. The pattern is an elaboration out of pre-existing details which always remain in it as potential elements expressing its process of making. It is this process, this programme of living, that brings out the details; to it they belong. But the very nature of such a programme involves variability, which, in reality, means

[1] Abstract of a lecture delivered at a Young Men's Association, Dromantine, Newry, Nov. 15th, 1886.

Digitized by Google

indetermination. At one stage in it nothing exists determining the element of structure-growth in reference to one future stage more than another; the element is determined by current circumstance, only under a condition of general conformity to the programme. Thus, in the infant the pattern of a structure—say of the brain—may be determined in a way unimportant as regards current state of being, but, being once determined, becomes deeply significant in subsequent states of being. In the child's brain a non-human detail existing in the programme of life can be introduced with impunity; there is nothing in the conditions of life at that stage, within certain limits, absolutely determining to the human rather than some other pattern. The determination of the pattern lies, to some extent at least, within the general limits of the programme. It would not be right to say that this is indetermination absolutely; it is only indetermination in respect of future detail. The programme potentially contains many patterns, the choice between which is determined under immediate conditions, allowing divergence in the initiation of detail, which obtains weight only subsequently. At a period in existence, therefore, what determines detail of specific pattern is wanting, or of small potency, and the characters of other patterns included in the programme are not rigidly excluded. Now, we know as a fact that abnormal elements of structure do actually enter the human pattern with impunity at an early stage, to become in after-life sources of ill-health; and in many instances a strong resemblance between these elements and elements of structure in lower animals is very apparent. The value of such observations is to be estimated, firstly, by the actual significant and determined nature of the resemblance and its generality; and, secondly, by the resemblance coming into the body of facts, which make a larger induction—say that of evolution. In the actual outcome, as each state of ill-health in the initial step is perhaps invariably a matter of local detail, the true nature of the state becomes of increasingly difficult recognition. When a part grows after a wrong or obsolete pattern, it has to reckon with the parts and processes which do not misbehave, with the result that the actual form of the pattern is disturbed or obscured. It is only in certain cases that an unfitting pattern can be maintained, its unconformity to the specific pattern leading usually to profound disturbance. In some cases, however, the human system is more or less tolerant of abnormal patterns of structure, and when this happens they are found generally to correspond to patterns normal in other animals. No two human bodies are quite alike, and the difference in each case from an assumed specific type is at bottom, as a rule, due to change to a non-human pattern. This is the general form of variation. Sometimes it can be seen even in disease—that is, when unconformity induces disturbance, when the pattern is maintained with difficulty. In gout we have a mode of digestion in essential particulars, normal in birds and reptiles, manifesting itself complicated with unconformity in man. But in proportion as the unconformity becomes more decided, facts of similarity are liable to be taken as accidental and non-significant. A superficial likeness is observable between certain diseases of the human skin and skin structure in fishes. The fact should not be ignored. It may be, indeed it is probable, that reversion to fish-like types of structure occurs in man disguised by extreme unconformity to the human type. This in all probability would be found in skin and nerve disease.

Possibly it may be thought that I have not said how our health is made. In the present state of knowledge I could not do so. All that can be done is to state the problem in various tentative ways; to approach it, to realise it. If the doctrine of evolution be taken, we must expect the facts of health and ill-health to find a place in it. All I could do was to indicate that place in a general, and I fear unskilful, way. The doctrine in its present state does not prove the views I have explained, nor do these views add much to the induction; but at the same time no other working hypothesis exists to give our observations of states of health coherent or intelligible connexion.

Poyntzpass, Newry.

The annual meeting of the Governors of the Leicester Dispensary was held on the 31st ult., when satisfactory financial and general reports were presented and adopted.

RESULTS OF

MAJOR AMPUTATIONS TREATED ANTISEPTICALLY IN THE NEWCASTLE-ON-TYNE INFIRMARY,

FROM APRIL 1ST, 1878, TO DEC. 31ST, 1886.

BY FREDERICK PAGE,

SURGEON TO THE NEWCASTLE-ON-TYNE INFIRMARY; EXAMINER IN CLINICAL SURGERY, UNIVERSITY OF EDINBURGH.

IN the year 1884 I published in THE LANCET a table (No. I. below) giving the results of major amputations performed antiseptically in the Newcastle-on-Tyne Infirmary during a period of four years and nine months—from April 1st, 1878, to Dec. 31st, 1882,—and contrasted the mortality with that of a similar period, an account of which appeared in THE LANCET, I think in the year 1873.

TABLE I.

	For Injury.			For Disease.			Total.
	No.	Recov.	Died.	No.	Recov.	Died.	
Hip-joint	0	0	0	2	0	2	2
Thigh	16	11	5	37	34	3	53
Knee-joint	3	2	1	4	4	0	7
Leg	20	16	4	24	24	0	44
Ankle-joint	4	4	0	16	16	0	20
Shoulder-joint	3	3	0	2	2	0	5
Arm	11	9	2	6	6	0	17
Forearm	8	8	0	4	4	0	12
Wrist	0	0	0	0	0	0	0
Total	65	53	12	95	90	5	160

I am sorry that I am not in a position to give the precise cause of the seventeen deaths, but the mortality was 10·6 per cent. and showed a marked decrease from that of the previous report. From injury the mortality was 18·4 per cent., from disease 5·2 per cent.

Table II. gives the results of major amputations performed antiseptically in the infirmary from Jan. 1st, 1883, to Dec. 31st, 1886, a period of four years, with the precise

TABLE II.

	For Injury.			For Disease.			Total.
	No.	Recov.	Died.	No.	Recov.	Died.	
Hip-joint	0	0	0	9	6	3	9
Thigh	10	9	1	54	51	3	64
Knee-joint	4	4	0	1	1	0	5
Leg	21	21	0	26	24	2	47
Ankle-joint	12	12	0	30	29	1	42
Shoulder-joint	2	2	0	3	3	0	5
Arm	14	14	0	6	5	1	20
Forearm	13	12	1	10	10	0	23
Wrist	7	7	0	0	0	0	7
Total	83	81	2	139	129	10	229

cause of death in each of the twelve fatal cases. The mortality is 5·4 per cent., for injury 2·4 per cent., for disease 7·1 per cent. Now let us examine the precise cause of the twelve deaths in this table.

Injury.

1. Thigh. The only death after a primary amputation. A man. Died in a few hours from shock and loss of blood.

2. A man, admitted with tetanus from a crushed hand. Forearm amputated. Died in twenty-four hours from tetanus.

Disease.

3. Amputation at hip. A woman aged twenty-one years, whose hip had been excised a year before. Had albumen in her urine. Died in eight hours.

4. Amputation at hip. Man, aged fifty years, much run down by long-continued suppuration. Died in a few days from exhaustion. No sign of blood poisoning.

5. Amputation at hip. Man, aged thirty years. The same remarks apply to this as to the preceding case.

6. Thigh. Man, aged forty-six years, suffering from phthisis and suppuration of knee-joint. Died in seven weeks from phthisis.

7. Thigh. Man, aged fifty-three years. Amputation

Digitized by Google

through middle third for spontaneous gangrene of foot and leg. Died in forty-eight days from recurrence of gangrene.

8. Thigh. Man, aged sixty-two years. Limb amputated close to hip for long-standing necrosis of femur. Died in a few days from exhaustion.

9. Leg. Man, aged sixty-two years. Amputated just below the knee for ulcers on both legs of twelve years' standing. Died of pyæmia. Infection probably arose from ulcer on other leg.

10. Leg. Man, aged fifty-five years. Amputated just below the knee for spontaneous gangrene of foot. Died from recurrence of gangrene of the stump.

11. Ankle. Old man, just recovered from typhus. Spontaneous gangrene of both feet. One removed at ankle-joint. No attempt at repair. Death in a few days from inanition.

12. Arm. Woman, aged seventy-seven. Admitted from a workhouse with suppuration of the elbow and bed-sores. No attempt at repair. Death in a few days from inanition.

If we compare the above tables we are struck by two circumstances. 1. The mortality from amputation has fallen from 10·6 per cent. during the first period to 5·4 per cent. during the second. This I consider most satisfactory. 2. The usual relative mortality of amputation for injury observed in the first table is reversed in the second. In the first, 18·4 per cent. of the amputations for injury and 5·2 per cent. for disease were fatal, but in the second 2·4 per cent. from injury and 7·1 per cent. from disease died. This is an unusual and remarkable experience. I believe both results to be due to the almost entire absence of pyæmia. Blood poisoning was the great cause of death after amputation. It has almost ceased to operate with us. Consequently the mortality from amputation generally has fallen, with the result that in cases of disease amputation is now resorted to where formerly it would have been refused. A glance at the causes of death I have just given in detail will, I think, support this view. Amputation at the hip in the adult is a very fatal procedure; so is amputation for spontaneous gangrene. Six of the twelve deaths recorded followed such operations, and I question whether some years ago any of them would have been performed. I have been much struck by the following quotation and table from the last edition of Mr. Erichsen's work on surgery:—

"In the following table may be seen the results of 307 consecutive cases of amputation performed at University College up to May, 1871. Of these, 79 died, yielding as nearly as possible a mortality of 25 per cent.

Seat.	Injury.			Disease.		
	Cases.	Deaths.	Per cent.	Cases.	Deaths.	Per cent.
Thigh	39	23	59·0	86	18	20·9
Leg and foot ...	44	14	31·8	74	10	13·5
Shoulder and arm	12	5	41·6	24	8	33·3
Forearm	8	0	0·0	20	1	5·0
	103	42	40·7	204	37	18·1

Our experience in Newcastle at the present day is very different; for, as will be seen from Table III., we have had 382 consecutive operations with 29 deaths (7·5 per cent.)

TABLE III.—*Major Amputations treated Antiseptically in the Newcastle-on-Tyne Infirmary from April 1st, 1878, to December 31st, 1886.*

—	For Injury.			For Disease.			Total.
	No.	Recov.	Died.	No.	Recov.	Died.

Wrist	7	7	0	0	0	0	7
Total	148	134	14	234	219	15	382

Mortality 7·5 per cent.

I would further point out that Mr. Erichsen's table contains no amputation at the hip or at the wrist, while the Newcastle table has 11 amputations at the hip with 5 deaths, and 7 at the wrist with no death. If these cases were excluded from the Newcastle table, the number of amputations would be 364 with 24 deaths—a mortality of 6·5 per cent. Mr. Marcus Beck tells me there has been no death from pyæmia after an amputation in University College Hospital since 1880, so that I entertain no doubt the mortality there since May, 1871, will be found to be very considerably less than 25 per cent.,—possibly even lower than with us.

CASES OF

GUNSHOT INJURIES, WHICH OCCURRED AT SHWEBO, UPPER BURMAH.

BY JOHN LUCAS, M.D., F.R.C.S., &c.

(Compiled from notes taken at the time by Mr. B. MURPHY.)

CASE 1.—Private W. D——, Royal Welsh Fusiliers, was wounded in action on Dec. 27th, 1885, at Zeedaw (three miles from Shwebo), the distance at which the injury was inflicted being about twenty yards. The bullet (a large, irregularly-rounded piece of lead), entered below the outer third of the left clavicle, and made its exit at the lower part of the posterior margin of the deltoid muscle, passing through the humerus, about two inches below its neck, causing a compound comminuted fracture. The large vessels and nerves escaped injury, as also the shoulder-joint, with the exception of a continuation of a splinter into it. Chloroform was administered, and an exploratory incision made, and the wound of exit was enlarged to permit of the removal of some loose spiculæ of bone. The wounds were then dressed antiseptically, and the arm placed on a splint. The patient, who was a strong and healthy young man, suffered very little from shock, and there was but little loss of blood from the time of the injury to the completion of the exploratory operation.—Dec. 28th: The patient had a fair night's rest after a hypodermic injection of morphia (half a grain). The wounds were re-dressed. Evening temperature 100°.—29th: Wounds re-dressed. Had a fair night. Wounds looking well, discharge being slight and sanious. Morning temperature 99·4°; evening 100·4°.—31st: On removing the dressings the discharge was found to be free and purulent, and had a slight odour. There was a considerable amount of swelling of the arm and tissues covering the joint. Some small sloughs were found in the anterior wound and removed. The patient was restless during the night and wandered slightly. Morning temperature 101·4°; evening 102°. The wounds were syringed out with strong carbolic lotion, a drainage-tube inserted, and dressed.—Jan. 1st, 1886: The patient had a very good night after a hypodermic injection of half a grain of morphia; felt no pain; discharge free and without smell. Morning temperature 98°; evening 99·2°.—7th: Quantity of discharge very great, but without any offensive odour. The patient was much pulled down, though he took nourishment well. A mixture of iron and quinine to be taken thrice daily, and six ounces of port wine ordered.—20th: Patient continued to do fairly well. It was subsequently reported that the wounds had quite healed, and that there were prospects of a fairly useful limb.

CASE 2.—Private C. C——, aged thirty-two, Royal Welsh Fusiliers, was also wounded at Zeedaw on Dec. 27th, 1885. The bullet passed into the right thigh, about four inches below Poupart's ligament and about two inches external to the course of the femoral artery. On examination the femur was found to be fractured near the surgical neck; the bullet could not be found, but was supposed to be lodged in the bone or in the soft tissues immediately behind it. There was a good deal of hæmorrhage at the time of injury, which was controlled by pressure, and the patient suffered considerably from shock. The patient was a spare, sickly man, and had suffered much from fever when in India. Stimulants were given to rally him from the shock, and the wound lightly dressed. The wound was about the size of a four-anna piece, and would barely admit the first joint of the little finger.—Dec. 28th: The patient had a fair night after the administration of a hypodermic injection of morphia. Pulse still feeble; morning temperature 97·6°. Takes nourishment well. The dressings were changed. There was little discharge, but the whole thigh was immensely swollen.

Digitized by Google

Evening temperature 99·2°.—29th: The patient looked brighter this morning; had a fair night; pain not severe. Morning temperature 99°; evening 101·2°.—30th: The patient was very restless during the night; complained of severe pain in the hip-joint. Discharge from wound free and purulent. Bowels moved once after an enema of warm water. Morning temperature 101°; evening 101·4°.—Jan. 1st, 1886: During the night severe spasms came on in the injured limb, clonic in nature, and recurring every few minutes. During the spasm the muscles on the outer side of the thigh were drawn up, and caused great agony. The swelling had much increased, and the discharge was very profuse, being jerked through the wound with each spasm. The patient's body was bathed in a cold clammy sweat; pulse feeble and wiry, and very quick; the face had an anxious, scared look. The muscles of the jaw and other parts of the body were quite free from spasm or stiffness. Dressings changed. A hypodermic injection of half a grain of morphia to be given every three hours; stimulants and nourishment to be kept up.—2nd: The spasms continued, were more frequent, and were aggravated by the slightest movement of the patient himself or anyone near him. The effort to drink would bring on a severe spasm. The patient continued thus to suffer great agony till 8 P.M., when he expired from pain and exhaustion. The tetanic spasms were confined to the injured limb up to the last. No post-mortem could be held, nor in any of the following cases.

CASE 3.—Private S. G——, aged twenty-four, was wounded at Yatha on January 12th, 1886, the bullet entering at the left shoulder about half an inch below the centre of the spine of the scapula; and, judging from the man's position when hit, which was lying and facing the enemy, the missile passed downwards, forwards, and somewhat inwards, and lodged in the left lung (the exact site of which could not be traced). The hæmorrhage from the wound was slight, but pain was complained of and referred to the posterior surface of the heart; and there was a good deal of anxiety manifested by the patient, with the subjective feeling that the heart itself had been injured. A hypodermic injection of half a grain of morphia was given, but without much effect. A broad roller bandage was applied round the chest, and the wound lightly covered with carbolised lint. He had to be carried in a dooly two long marches to Shwebo, which he bore fairly well. He spat up some blood, and showed symptoms of acute pneumonia on the third day of the injury. On physical examination, a considerable amount of emphysema was observed on the fourth day in the muscles of the left side of the back, indicating the escape of air from the injured lung. A clear tympanitic note on percussion over the left lateral part of the thorax pointed to the occurrence of pneumothorax, and there was collapse of the left lung, as shown by dyspnœa, restlessness, rapid respiration, &c. The decubitus was that of orthopnœa. The above was the condition during the first four days of the receipt of the injury.—Jan. 17th: Patient scarcely slept during the night, though he had an opiate; respiration difficult; pain in the chest very great; pulse hard and wiry; skin hot.—18th: The man was very restless; respiration more difficult; he could not articulate on account of the severity of the dyspnœa; pain in the chest severe and constant; pulse feeble and quick, and body bathed in cold sweats. Opiates were continued, but without much effect.—19th: The patient was getting exhausted from pain and sleeplessness, and gradually sank.

CASE 4.—Private C. D——, aged thirty-two, was wounded at Zeedaw on Dec. 27th, 1885, by two bullets, the first entering the left groin immediately over the centre of Poupart's ligament. The man feeling himself wounded, called out to a comrade for assistance, and as he was turning to the left he received a second bullet in the abdomen, about two inches below and to the right of the umbilicus. The hæmorrhage from the first wound was very severe, and was controlled with difficulty by a pad and pressure. The wound in the abdomen was a small one, of the size of a four-anna piece. The little finger could be passed into it up to the first joint. There was no protrusion of gut or omentum, though these could be seen. The destination of the bullet in both wounds could not be discovered. The patient suffered severely from shock; he could not pass urine, and only a few ounces of it, which was clear, were drawn off with a catheter. Pulse feeble and thready. Stimulants were given freely, but the patient never rallied, and died ten hours after the infliction of the injury.

CASE 5.—Corporal J. C——, aged twenty-nine, was killed at Zeedaw on Dec. 27th, 1885. The bullet entered the chest immediately below the inner third of the left clavicle, grazing its lower border, wounding the subclavian artery, and lodging in the muscles at the root of the neck. Before assistance could be rendered the man died of hæmorrhage. The distance at which the injury was inflicted was very close (about fifteen yards).

CASE 6.—Private D. R——, aged twenty-seven, was wounded at Zeedaw on Dec. 27th, 1885. The bullet passed deeply through the calf of the leg, entering at the inner side close to the edge of the tibia, and about two inches below the tuberosity, and making its exit about four inches below the lower angle of the popliteal space, a little external to the middle line of the calf, passing in a direction outwards, downwards and backwards. There was a considerable amount of swelling about the leg and foot, and the pulsation of the posterior tibial or dorsalis pedis arteries could not be felt; there was also some swelling of the tissues over the knee-joint, but the joint itself did not seem affected. There was considerable hæmorrhage at the line of injury—easily controlled, however, by pressure.—Dec. 28th: Dressings changed. Parts much the same. Had a fair night after the administration of a hypodermic injection of morphia.—29th: A quantity of sanguineous serum exuded from the wound on the removal of the dressing. Complained of inability to pass urine; a No. 8 catheter was passed, and a few ounces drawn off.—30th: Swelling much diminished; discharge from wound slight and purulent; appetite fair; bowels moved after an enema. Morning temperature 102°; evening 102·4°.—31st: Patient slept well after a hypodermic injection of morphia. Condition of leg the same; discharge free. Morning temperature 100°; evening 100·8°.—Jan. 4th, 1886: Patient doing well. Suffered from a little diarrhœa yesterday, treated with an astringent. Wounds doing well and discharge healthy.—7th: The discharge has become putrid, and, some sloughs having separated, a large cavity was disclosed in which the posterior border and surface of the tibia were seen denuded (over a large area) of periosteum. From the position in which the patient *would* keep the limb, which was with the knee bent, whilst lying on his back, the pus descended along the muscular intervals and along the interosseous membrane, and a deep and large abscess was formed. The limb was bandaged tightly from below upwards, which proceeding caused a large quantity of putrid pus to exude through the wound; the cavity was then syringed out with carbolic lotion, the bandage, which had been removed to syringe the cavity, replaced, and the limb placed on a straight splint.—12th: The discharge from the wound was now much less offensive, and its quantity less. The swelling in the calf of the leg had almost disappeared. The patient was rather anæmic, and had lost much flesh. Quinine and iron were ordered to be administered.—15th: The patient was now on a fair road to recovery; his appetite was good, he slept well, and, though an ugly-looking cavity still remained, hopes existed that it would soon fill up. The man left Shwebo in this condition, and no reports have been received concerning him since his departure.

CASE 7.—Private W. T——, was wounded at Zeedaw on Dec. 27th, 1885. The bullet entered the left arm an inch and a half below and internal to the olecranon, and passed in a direction upwards, forwards, and outwards, passing through the elbow-joint; it lodged immediately under the integument about three inches above the external condyle of the humerus, where a small longitudinal incision was made and the bullet extracted. The pulsation on the radial artery was distinct, and there was little bleeding from the wound. A drainage-tube was inserted into the lower wound, and the arm placed on an angular splint. On probing the wound rough bone could be felt, but no separate fragment, nor could the probe follow the course of the bullet for more than two inches.—28th: Swelling about the elbow-joint considerable, discharge consisting of a little pus and synovial fluid. Pain severe during the night. Morning temperature 100°; evening 101·4°. The wounds were re-dressed, and the whole arm and forearm wrapped in spongio-piline wrung out in hot water.—29th: Swelling of joint much diminished; discharge free and purulent. The patient slept well after a hypodermic injection of morphia, and the pain was less severe. Morning temperature 100°; evening 100·8°.—Jan. 7th, 1886: Patient continues to do fairly well. Appetite fair. The temperature is now normal. The swelling about the joint has quite disappeared,

Digitized by Google

and the wounds are discharging healthy pus. The patient is much pulled down, and looks very anæmic. Quinine and iron were administered.—15th: The patient's condition is much the same; wounds still discharge a quantity of pus, which now has a slight odour and looks less healthy; no fever; appetite fair; takes a little exercise in the open air. Shortly afterwards the patient left the station, with fair prospects of ultimate recovery, though the joint would probably be stiff and useless for a long time to come.

CASE 8.—Private G. D——, aged twenty-four years, was wounded at Zeedaw on Dec. 27th, 1885. The bullet entered the right forearm over the insertion of the tendon of the biceps muscle, and passed upwards, backwards, and outwards through the elbow-joint. One piece of the bullet was extracted from the wound, along with some débris of bone; another piece was found a few days after about half an inch above the external condyle of the humerus, embedded in the triceps muscle, near its insertion. The biceps tendon and vessels in the angle of the elbow escaped injury. There was not much bleeding at the time of injury. The limb was placed on an angular splint, and the wounds dressed antiseptically.—Dec. 28th: The arm was very painful, and much swollen; a hypodermic injection of morphia had not much effect in producing sleep. The arm and forearm were wrapped in a large piece of spongio-piline wrung out in hot water.—Jan. 1st, 1886: Swelling rather less. Arm still very painful; discharge consisted of pus and some synovial fluid. Morning temperature 100°; evening 100·8°.—3rd: On this day a second piece of lead was discovered and removed. Patient much the same. Evening temperature 101·2°.—4th: Swelling somewhat less than yesterday; some débris of bone daily removed; discharge not offensive at this time. Pain considerable, and he could not sleep well, though hypodermic injections were given nightly. Morning temperature 100°; evening 100·4°.—12th: Discharge looking healthier; swelling slightly less. The patient was looking anæmic, and had lost much flesh since the injury occurred. He left this station shortly afterwards in the condition above described.

CASE 9.—Lieut.-Colonel R. S—— was wounded at Yatha on Jan. 12th, 1886. The bullet entered at the right cheek, just below the outer border of the malar bone. It caused a wound about the size of an eight-anna piece, from which there hung a shred of the facial nerve, which had been divided, causing facial paralysis. The facial artery was also divided, which gave rise to severe hæmorrhage on the field. It was controlled by digital pressure on the proximal portion of the artery as it crosses the lower border of the maxillary bone. The hæmorrhage caused considerable prostration, and rendered any attempt at searching for the bullet futile. The wound was dressed lightly with carbolised lint, and a hypodermic injection of a quarter of a grain of morphia given. This, not having much effect, was followed by a grain of opium three hours later.—Jan. 13th: A slight undefined swelling was discovered in the neck, a little behind and below the right mastoid process. It was thought that this was the bullet, so an incision was made over the swelling and a thorough search made, but no bullet could be discovered. It was then thought probable that the bullet must have lodged behind the right zygomatic process, where it was resolved to leave it for the present or until some sure sign pointed to its exact site. There was no injury to any bone apparent, and on examining the part through the mouth no trace or sign of a bullet could be detected.—20th: The patient recovered from the prostration caused by the hæmorrhage and could move about. The disfigurement caused by the facial nerve being divided was much less marked. The wound was open and discharged daily a small quantity of healthy pus. In this condition the patient left the station for England. No account of him has since been received.

CASE 10.—Lieutenant G—— was wounded at Yatha on Jan. 12th, 1886. The bullet passed through the fleshy part of the thigh about three inches above the patella, in a direction backwards and inwards to the inner side of the femur, the vastus internus muscle being pierced. There was no constitutional disturbance in this case, and very little hæmorrhage, though for a few days there was slight swelling, and a little heat was felt about the injured part. The wounds were dressed antiseptically, and the limb placed on a splint. The case progressed well, the wounds being nearly healed when the patient left the station on the 21st.

CASE 11.—Lieutenant L. C—— was wounded at Yatha on Jan. 12th, 1886. The bullet passed through the skin and subcutaneous tissue of the popliteal space of the right leg, making a wound of entrance and one of exit, and leaving a narrow isthmus of skin and subcutaneous tissue between them. The tendons in the popliteal space were uninjured, though one of them was exposed. There were no untoward symptoms, and the wounds quickly healed, leaving only a temporary stiffness of the part. It is noteworthy that in this case and in the former cases where a bullet had made its exit, the wounds of exit were in no case larger than the wounds of entrance; on the contrary, they were in many cases smaller.

SURVIVANCE AFTER GUNSHOT WOUNDS OR OTHER INJURIES OF THE HEART.

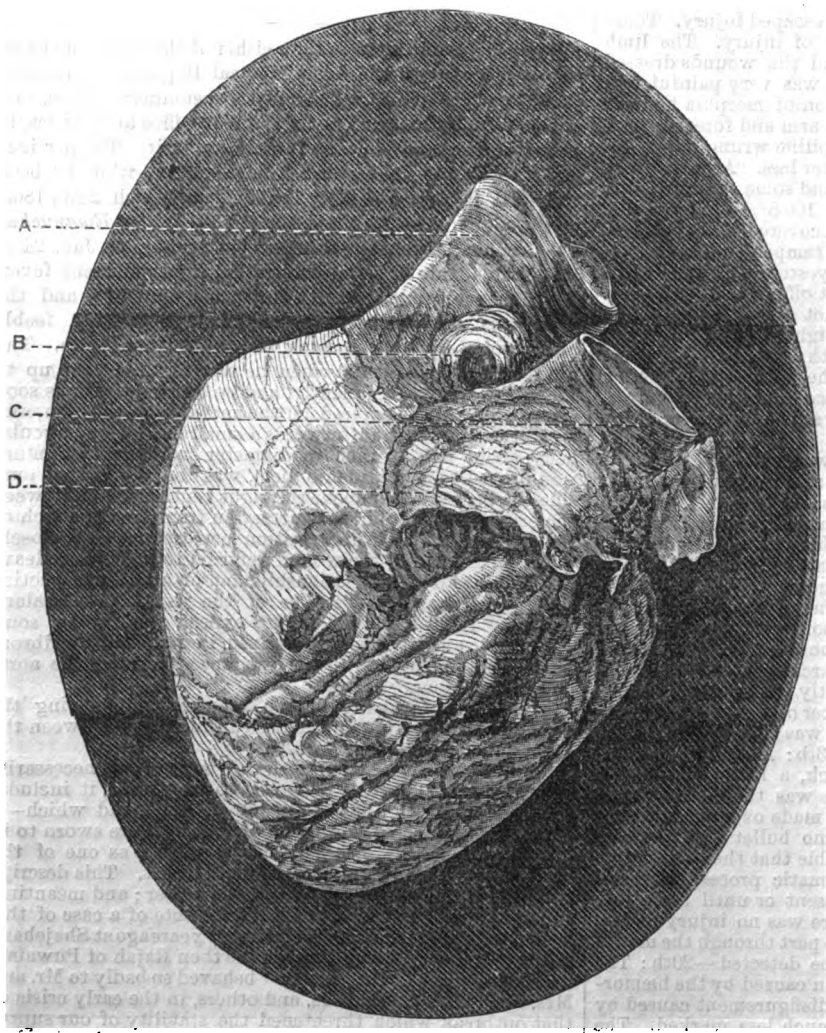
BY BRIGADE-SURGEON W. CURRAN,
(ARMY MEDICAL DEPARTMENT (RETIRED).

(*Concluded from page 674.*)

OF even greater interest than either of the foregoing cases is one recorded in the Army Medical Department Reports for 1875, p. 286, which I am induced to summarise here, as I am enabled, by the courtesy of the War Office authorities, to submit at the same time an illustration of it. The particulars of it stand briefly thus: A naval officer, who had been wounded at Taranaki, New Zealand, on March 28th, 1860, was brought on board the hospital ship *Victor Emanuel* at the Gambia (?) from the front, on the evening of Jan. 24th, 1873-4, in a state of great prostration from remittent fever. His illness commenced with a violent diarrhœa, and the symptoms on admission were great prostration, feeble husky voice, irritable stomach, and cold, clammy skin. The pulse, which stood at 120 when he was first seen, ran up to 128 a few days subsequently, and he became delirious soon afterwards.....He expired on the morning of the 27th, and on section four hours afterwards a small hard heavy circular body, about half an inch in diameter (which, on examination proved to be a leaden bullet), was found encysted outside the pericardium, above the right ventricle, and between the origin of the pulmonary artery in front, and the arch of the aorta behind. This position corresponded so closely with the cicatrix of the wound referred to above as to leave no doubt as to their relationship, and on a closer inspection this bullet was found to be of the usual New Zealand pattern. It had, as we might expect, undergone some alteration, and it was firmly fixed in its place by fibrous bands, that enclosed it in the interspace between the aorta and the pulmonary artery.

Fig. 2 is a drawing of the preparation, showing the bullet *in situ*, resting on the pericardium, and between the aorta and the pulmonary artery.

As to my own connexion with this matter, it is necessarily very limited. Limited, however, though it be, it includes the case to which I have already adverted, and which—if we may accept the descriptions of it that were sworn to in a court of justice—may be fairly regarded as one of the rarest of its kind in the literature of our art. This description will be more fully set forth hereafter; and meantime I may be here permitted to give a brief note of a case of this kind that was given me *viva voce* many years ago at Shajehanpore by that very shaky subject, the then Rajah of Puwaine, near Moradabad. This man had behaved so badly to Mr. and Mrs. Probyn, Mr. Edwards, and others, in the early crisis of that outbreak which threatened the stability of our supremacy in India, that he only escaped the halter by the skin of his teeth; and being at this time on his best behaviour, he condescended so far as to pay court even to me. This was how the interview between us was brought about, and this was the medium through which I obtained these particulars. One Beeka, a syce (groom), was, while in the service of this petty chieftain, in putting his master's long single-barrelled pistol into his left holster, done to death in this wise. The edge of this holster—a coarse native one—having caught the cock of the pistol while the latter was descending into it, forced it back and so "set" it. Seeing this just as he had mounted, the Rajah endeavoured to replace it in its proper position and thus caused the pistol to explode. The syce, who was at this critical moment standing by his horse's head, or rather who was adjusting the stirrup to his master's shoe, was just in the position to receive the contents of this weapon. Accordingly, after grazing the back



Digitized by Google

of his right hand and passing through the metacarpal bone of the thumb and index finger of the left hand, it emerged through the soft part of the palm of this member without further injury to any of its tissues. It then entered the chest between the fifth and sixth ribs on the left side, two inches and a half to the right of and one inch below the left nipple, and then finally made its escape lower down between the eleventh and twelfth ribs of the opposite side posteriorly. Beeka survived this injury for nearly fifty-two hours, and then died quietly of internal hæmorrhage and exhaustion.

A necropsy, that was instituted by, I presume, a native doctor three hours afterwards, disclosed the following appearances, and I may here add that I have notes of a very similar case that occurred at an election in Ireland several years ago. In this instance a Captain King, who was accidentally shot by his nephew in a crowd, appears to have been at the time in a kneeling or crouching posture, for the medical man who examined the remains found that the bullet, which entered the chest on a level with the nipple of the right breast, "extended inwardly in an angle of thirty-five degrees down to the heart," and it was afterwards shown that though the two chambers of the heart had been pierced, yet that Captain King "did live and walk after he had received this wound."

On removing the integuments of the chest, it was found that after this bullet had entered the chest as above, it [illegible]

FIG. 2.

A, The aorta. B, The bullet. C, The pulmonary artery. D, Part of the pericardium.

inch of the wall of the left ventricle. Passing thence through the diaphragm to the left of its crus, it grazed the stomach, and finally escaped from the body in the interspace already indicated.

Passing now for a moment to that valley[1] which has been the scene of so much change and contention, so much anarchy and bloodshed in the past, and which has also witnessed the curious case I have already adverted to, I must premise, by way of introduction to this, that blood feuds, the heritage of ages and the scourge of families, have ever been rife in it. So envenomed has this custom become that every village in it had once its watch-tower, whence an armed band guarded the growing crops, and whence also the armed herd or ploughman went forth to tend his flock or turn up the soil. So inveterate was it at one time, or may be still, that, as Dr. Bellew observed, the very cattle of opposing tribes or factions are afraid of one another, while the children crawl cautiously by the walls of their houses, rather than pursue their frolics in the open field. The atmosphere of the place savours, in short, of distrust and suspicion; every office or relation of life is imbued or embittered with them; and it was in one of these village feuds that the case occurred which I have more than once already indicated, and with which I will now close this series.

A man named Meera Khan was tried in the Court of Sessions at Peshawur on September 16th, 1873, before Mr. Elmslie, for murder, under the following circumstances. Blood feuds, handed down from generation to generation, are, I may observe, not uncommon in this locality. A native named Kadir, having been shot while lying on his cot on the night of June 2nd, 1873, made a dying statement before witnesses to the effect that Meera Khan had shot him while Muddut, Meera Khan's brother, was standing by. The motives for the perpetration of this crime were revenge and jealousy, and the police-sergeant who arrested the prisoner "found him lying on a bed in his house. He had his payjamas (drawers) drawn up for an inch or two. . . . I at once put my hand on his heart," continues the sergeant; "it was beating perceptibly. I said, 'Why is your heart beating?' He replied that he had come in from work tired, and had therefore lain down with his trousers slightly tucked up, and he added that his heart was beating because I had arrested him. I then told him that he was charged with murder." The sub-assistant surgeon who examined the body deposed to the presence of two bullet wounds in the heart, and Mr. Elmslie, in summing up, said, "*Primâ facie*, there is sufficient evidence before the Court to show that the wounded man did denounce his assassins just before he died . . . . but, judging from the evidence of the sub-assistant surgeon, it seems extremely doubtful whether the accused could have spoken after his heart and left lung had been perforated in four places."

The following is a *verbatim et literatim* copy of the certificate of death that was given in the case by the subordinate here referred to: "I, Chetun Shah, sub-assistant surgeon of Peshawur, on the 2nd of June, saw Kadir (or examined). He bore the mark of a bullet in the right arm, and [illegible]

[1] For additional information about this valley, its geography, &c., see my paper on Peshawur Fever [illegible] Indian Annals of Medical Science for July, 1878.

Digitized by Google

of the hand was black. Two bullet wounds were apparent on the left side, on the side of the heart, which organ they had penetrated. The heart was, in fact, wounded in four places, from which he died immediately. His shirt was burned, and these bullets must have been fired from very near. There must have been two shots, no more, from either a double barrel or a single barrel."

While putting the evidence before the assessors, Mr. Elmslie said that Chetun Shan "wrote on the 2nd of June, just after inspecting the body, that death must have been instantaneous." Mr. Shah, however, slightly modified this opinion subsequently, and said that "death must have occurred very shortly after the infliction of the wound"; and a medical man who was referred to in the matter said that "the phraseology describing the nature of the wounds is so vague, that it is impossible to base an opinion thereupon as to the power of the deceased to have recognised his assailants, and to have spoken after the infliction of the wounds." The point then turned on the possibility of the deceased's "living for some minutes and speaking intelligently or recognising his assailant." The certificate (covering letter 3) given by the sub-assistant surgeon on the 2nd of June runs as follows: "—— begs to report that the cause of death in this case was a bullet wound passing through the right hand front wall of the chest, heart, the left lung, and the chest wall on the other side. Four bullets that have been found embedded under the skin of the chest wall are herewith forwarded. Death must have been instantaneous."

This functionary added, in another examination that was held before the magistrate, that the heart itself was perforated in two places: "I do not mean by two bullets, but by four, as the marks of entrance and exit were visible in four places. Two bullets had entered the right auricle and two had entered the right ventricle. The bullets went direct through

FIG. 3.

These slugs or bullets weigh between them 11 drachms and 48 grains. The largest of them weighs 3 drachms and 56 grains.

the heart, and not in a slanting direction through the fibres. The edges of all the bullet wounds were ragged to some extent, not quite sufficient to close the openings. The pericardium was full of blood, and the cavity of the chest on the left side was also full of blood. The left lung was perforated, but this would not affect the power of speech immediately." There appears to have been some confusion, if not contradiction, in these statements, but for this I am in no wise responsible. I give the particulars of the case as they were given to me. (See Fig. 3.)

Paraphrasing Mr. Shah's evidence, the magistrate continues to say that "it does not seem impossible that he (the deceased) could have spoken after he was shot, but it is not probable. There are instances of men having lived for some hours after having been shot through the heart, and the lacerated edges of the wounds in this case may, to some extent, have impeded the escape of blood from the heart, and so prolonged life to some extent. It is quite impossible that deceased could have carried on a lengthened conversation, but it is quite possible that he may have said a few words. The wounds would not affect his power of speaking intelligibly, supposing that he was able to speak at all. I have no doubt that he was able to open his eyes after he was shot, but whether he was able to recognise his assailants or not would depend entirely upon the amount of light. With regard to the word 'instantaneous' used in my docket, I merely meant that death must have occurred speedily."

The acting civil surgeon, Dr. Andrew Skeen,[2] endorsed this opinion in the main, and otherwise delivered himself in the matter as follows:—"I have heard the statement of sub-assistant surgeon Chetun Shah, and concur with him. In the case of a wound of the heart in cases where the shock is not the immediate cause, death usually occurs from the escape of blood into the pericardium, thereby impeding the heart's action; but in this case, from the evidence of the sub-assistant surgeon, it would appear that the flow of blood was to some extent retarded by the jagged edges of the wounds. The bullets moreover—which are before me—are small. I think it possible that the man may have given intelligent answers for a short time after he was shot—a very short time. Several cases are on record where severe wounds of the heart have not been followed by death for some hours, both gunshot wounds and stabs. Dr. Taylor quotes cases in which men shot through the heart have lived for some hours."

The assessors, Ram Dos and Mahrdil Khan, were of opinion that, according to the evidence, both the accused are guilty. They think that the deceased was able to take the names of his assassins, and that he probably saw them. The judge, Mr. Elmslie, after reviewing the evidence, which he considered conclusive against the accused, held: 1. That the deceased immediately on being wounded denounced both of the accused, and said that he had seen them. Also, that there is no reason to suppose that he spoke falsely. 2. That one of the witnesses, Sheemo, saw the accused retreating from the bedside of deceased immediately after the shot had been fired. 3. That Muddut came up shortly afterwards. 4. That the state of his clothes (Meera Khan's), and the beating of his heart, are strong grounds for supposing that he had been running shortly before. He then sentenced Meera Khan and Muddut to be hanged, and ordered that their property of every description be confiscated under the provisions of Section 6, Indian Penal Code.

An appeal having been lodged against this decision by the friends of the accused, the case came before the judges of the High Court at Lahore, who reversed the sentence mentioned above. Mr. Lindsay, who re-tried the case, acquitted both prisoners on the merits; and, after giving his reasons for this judgment, wound up the statement he made respecting it by saying that "the deceased's death was very sudden from the very nature of the wound inflicted, and it is open to doubt whether he spoke at all after being shot. He may have uttered a cry." And there the matter ended so far as the legal authorities of that province—the Punjaub—were concerned. I will only here add, that the first judgment was, in my humble opinion, the juster of the two, and it accords with my own personal experience and reading, that wounds of this kind are by no means so speedily or necessarily fatal as is generally supposed.

Bibliography.—To save time and space, and enable any reader who may desire to pursue this inquiry further to do so, I subjoin below a list in alphabetical order of the books or papers on which this essay is based, or to which more or less reference has been made in the course of it:—Army Medical Department Reports for 1873, vol. xv., p. 286. Art. "Heart," in Todd's Cyclopædia of Anatomy and Physiology. Barrington (Sir Jonah): Personal Sketches of his Own Times, vol. i., pp. 303-4. Bellew (H. W.): Journal of a Political Mission to Afghanistan in 1857, &c. The Book of Remarkable Trials and Notorious Characters, p. 363. Clark (F. Le Gros): Lectures on the Principles of Surgical Diagnosis, p. 247, &c. Chelius, translated by South, vol. ii., p. 96, &c. Chevers: A Manual of Medical Jurisprudence for India, and also his Commentary on the Diseases of India, p. 487. Dixon (Hepworth): Her Majesty's Tower, vol. iii., pp. 226-7. Holmes: A Treatise on Surgery, p. 195 (this contains a good account of the symptoms that are produced by wounds of this description). Edwards (Sutherland): The History of the Opera, vol. ii., pp. 190-3. Egan (Pierce); Anecdotes of Persons in every Walk of Life, p. 130: he quotes with surprise from the *Edinburgh Medical Journal* of the day the "Singular circumstance of a ball that was lodged (for a long period without injuring the animal) in the heart of a buck." Elphinstone: Cabool. Haller: Elementa Physiologiæ. Howell: Familiar Letters. Hume: History of England, vol. v., p 78, and vol. vi., pp. 200-1. The *Indian Annals of Medical Science* for October 1853, pp. 289-296; in this instance the ball probably entered the heart through one of the pulmonary veins; Dr. Chevers and Burton Browne could in no other way account for this phenomenon. *The Journal of Anatomy and Physiology*, vol. xx. James, Major, H.R.C.B.: Report on the Settlement of the Peshawur Valley (the best of its time), p. 5, &c. Philip (A. P. W. Wilson): An Inquiry into the Nature of Sleep and Death, pp. 68-9. Porter: The Surgeon's Pocket-book. Taylor (Swaine), M.D.: Medical Jurisprudence.

[illegible] kindly gentleman and very promising officer died, I regret to say, since I left India; and as regards further examples of this lesion, Dr. Bolleau kindly informed me, in 1879, that "there are only three other (than the above) cases of heart wound at Netley: A 146, no history; A 147, wound of ventricle; and A 148, surface wound."

DR. R. KOCH'S BACTERIOLOGICAL WATER TEST.

BY G. BISCHOF, F.C.S., F.I.C.

No. II.

IN THE LANCET of August 29th, 1885, I communicated a description of Dr. Koch's test after a visit to his laboratory. Since then some not inconsiderable material has been collected, partially the result of practical experience with the method by various experimentalists, partially of inquiries into its reliability; and it now appears appropriate to review the present position of the test.

As a matter of course, only such organisms can be indicated by it as will grow under any conditions whatever in gelatine peptone; secondly, only such as are not crowded out during culture by other microphytes; thirdly, such as will develop, generally speaking, within three days before the liquefying colonies have had time to overgrow the plate; and, fourthly, such as will grow at the temperature of culture. With regard to the first of these propositions, Dr. E. Klein stated in the discussion of a paper read by me last April on the subject before the Society of Medical Officers of Health that, for instance, a micrococcus which commonly occurs in our saliva absolutely refuses to grow in gelatine, and that in one case, where another yielded 150,000 colonies per cubic centimetre, the gelatine-peptone test only indicated some 5000, or about 3 per cent. of the former figure. He graphically explained the crowding out during culture of gelatine-peptone plates by stating that it was impossible, in mixed cultivations, nine times out of ten, to recover any pathogenic microphyte, however familiar. The organism of foot-and-mouth disease would only grow in this medium when no other forms were present; and even Dr. Koch's comma bacillus was soon crowded out by Finkler's, by the bacillus of anthrax, or by that which caused the conversion of urea into ammonia. The meaning of this is, that if in a bacterial mixture there exist some microphytes that grow fast and others that grow more or less slowly, the former will in a short time have, so to speak, taken possession of the available ground before the latter had time to take a footing. We have evidence that at least some pathogenic microphytes are likely to be amongst those crowded out, and will thus escape detection. Even after colonies of different microphytes have established themselves on the same plate, they are apt to engage in a fight for supremacy or existence like the most highly organised beings. I may add, from my experience, that Dr. Koch's comma bacillus, after keeping for five months at 18° C. in plugged test-tubes in gelatine peptone, had entirely disappeared from its pure cultures.

Dr. Koch has not, as far as I recollect, laid down a very definite rule as to the temperature at which samples should be cultivated, but in view of the fact that these cultures were made in his laboratory during my visit in the summer of 1885 in a basement room, without artificial heat, I adopted 18° C. The mixture recommended by Dr. Koch just commences to soften at this temperature, whilst even at 20° it is rather too liquid, and apt to give trouble. I am informed that a 10 per cent. gelatine-peptone meat extract (not infusion) may be prepared, which remains solid at 20° or 21° C., but that also this temperature is insufficient for the cultivation of a variety of microphytes must amongst others be concluded from M. Nocard's communication to the Central Veterinary Society of Paris, that the bacillus tuberculosis of birds requires as many as 38° C. for its culture. Such a temperature is obviously out of the question when employing gelatine peptone. Lastly, as regards the time of culture, it is unfortunate that the liquefying colonies generally render distinction of colonies impossible after two or three days' culture. We are thus left in ignorance on microphytes which take longer to develop, as for instance, according to M. Nocard, the bacillus tuberculosis of birds, the culture of which does not commence until the fifteenth day, and requires five or six weeks for full development. The organism of the disease which prevailed at Hendon in the winter of 1884-85, Dr. Klein has informed us, could be cultivated in gelatine but very slowly, and that of foot-and-mouth disease took many days to grow. The more weight should be attached to these considerations as the gelatine test is now mostly restricted to a statement of the number of total colonies. Why are those other subsidiary but important tests neglected which, as described in my first article, were originally recommended by Dr. Koch? Is this because the number of total colonies has in itself proved a sufficient indication in testing potable water, or because those methods failed to answer their purpose?

The question next arises, even if we obtain a more or less reliable figure of the numbers of colonies cultivated from a sample of water, what are we to do with it, how are we to interpret its teaching? In the paper read before the Society of Medical Officers of Health I arrived at the conclusion that the test affords no means of distinguishing between harmless and pathogenic microphytes, and that the number of colonies ordinarily found in water has neither a necessary or invariable connexion with wholesomeness, nor even with pollution. A sample may contain as many colonies as any potable water is likely to contain, and yet I think I proved in the paper referred to that on this account it need not in any way be injurious to health. Dr. Koch is of the same opinion, for he asks in one of his papers (1883): "Shall we declare air, water, or soil, *per se*, injurious to health if they contain a large number of microphytes? This, in my opinion, should not be attempted. We have not as yet succeeded in discovering amongst the many bacteria, which abound in the air, soil, and water, any pathogenic species." After this I confess it is not quite intelligible to me that we should be asked by him in the same paper to style a sample of water "very good," *because* it contained about one hundred colonies per cubic centimetre. In this difficulty the plea is set forth that, although the test may not yield absolutely reliable results by the indication of the number of microphytes present, the comparison of the number of total colonies cultivated in samples of unfiltered and filtered water affords a correct standard of the sanitary improvement effected by the filtration, because a reduction of a certain percentage in the total would similarly reduce the risk of introducing into our system any pathogenic microphytes which may have gained access to the source of water-supply. This seems equivalent to the admission that the test is incapable of giving information on any single sample, but that its scope is restricted to an indication of the relative improvement which may take place in a sample consequent to its purification in some way. Without any absolute standard, even this does not appear an easy task, for with a like number of colonies in two filtered samples, the improvement may in one case be judged very satisfactory and in another less so, the difference, however, being solely due to the worse condition of the unfiltered sample in the former case.

Let us follow this up by a practical case. Both Dr. P. Frankland and I independently arrived at the conclusion on the showing of the test that a variety of filtering media, given a suitable grain, depth of material, and rate of filtration, are capable of producing a remarkable reduction in the colonies, but that the action of spongy iron alone is lasting. This seemed so well to confirm the results previously obtained in a different way by Dr. de Chaumont, Professor E. Heyman, Mr. Frank Hatton, and myself, as almost to amount to a corroboration of the reliability of the test. I am afraid we can only accept this as a chance. Again, Dr. Frankland and I published for many months independent monthly reports on the effect of sand filtration on the metropolitan water-supply, and our figures once more agreed very satisfactorily. I thought right to discontinue my publications when the faith which I had at first in the teaching of these figures began to be shaken; Dr. Frankland still continues his in the water examiner's monthly reports.

How are we to explain a purifying action of sand? I am not aware of any evidence to show that this can essentially consist in anything but a mechanical separation of microphytes. Not one of the known means of destroying them can be supposed to exist in sand filters. Crowding out will take place within them, but its result will only be the annihilation, more or less, of some kinds, those

Digitized by Google

remaining flourishing so much the more. This, therefore, does not account for the destruction of practically the whole of the microphytes present, which is frequently indicated by the test here in London. Supposing we were to keep such water as is in this case ordinarily passed through the sand filters, in a sterilised glass vessel, protected against aerial contamination, its progeny would in all probability in a few days amount, on the showing of the test, to millions of colonies per cubic centimetre. Can we then understand the teaching of the test that, when we pass the same water month after month through a sand filter, it should continue to come out almost devoid of organisms? Even if we store the filtered water with the few organisms apparently left in it under like conditions as before, the test reveals in a few days thousands and thousands of colonies by self-multiplication, but such water may pervade a sand filter month after month without apparently any increase of life. Again, we know that microphytes grow in a comparatively short time, even through the fine pores of M. Pasteur's filter tubes; that they then frequently render the filtered water biologically more impure than the unfiltered. How is it that they should not grow through the much coarser pores of sand filters, and that those disseminated through them should not similarly multiply? Here we have a conflict of phenomena, which should somehow be explained before the teaching of the test can be accepted without very considerable caution. I am afraid of attempting any such explanation; but it is a biological fact that spores pass through filtering media which are capable of retaining the fully grown organisms. Supposing the latter were retained in sand filters and the former did not develop in gelatine peptone under the conditions of the test, the discrepancy would to some extent disappear; but the numbers of colonies indicated lose all meaning, as a sufficiency of spores might be in a sample to produce serious pathogenic complications even when the test indicated sterility.

I would further ask whether it is safe to argue that because a certain proportion of harmless microphytes, such as ordinarily occur in water, are mechanically separated, a similar proportion of pathogenic organisms would be removed? Let us not forget that we know very little indeed as yet about those pathogenic microphytes, which spread zymotic disease by the medium of potable water. The fact, for instance, that M. Pasteur has not succeeded in detecting the bacillus of hydrophobia, notwithstanding that there seems to be reason to assume its presence in certain liquids, leaves it an open question whether this is not due to a deficiency in the power of our microscopes, or to the diminutive size of the bacilli. I have no proof for this suggestion in the strict sense of the word, but, taking Dr. Koch's statement, "these bacteria, which I have called comma bacilli on account of their peculiar shape, are smaller than the tubercle bacilli," my suggestion is more likely to be correct than the reverse—viz., that pathogenic organisms could neither in size, form, nor habits be distinguished from non-pathogenic. If similar differences in shape as above do occur amongst pathogenic microphytes in water, some may pass through a sand filter which retains ordinary bacilli, similarly, as Professor Helmholtz observed, that the action of yeast did not extend through a membrane, whilst putrefactive bacteria penetrated it.

No doubt great progress has been made during late years in the filtration through sand, but it is curious to contrast the showing of the gelatine test with certain experiments made in 1870. In the thirteenth report of the Medical Officer of the Privy Council, Dr. Burdon Sanderson gives a table from which we calculate the average "zymotic property" of the supply of the London companies before filtration = 7·8, that after filtration (mean of samples from pump well and from main) being = 8·1. Dr. Sanderson naturally draws the conclusion that filtration exercises no perceptible influence on the zymotic power of water. Even practical experience seems opposed to the contrary teaching of the gelatine test; for how can we reconcile this with the experience at Lausen, where there was a more perfect natural filtration than is attainable by artificial means, and yet the morbific principle passed through, causing an epidemic? Nevertheless, the test should on no account be laid aside. If we bear in mind the crude state in which it was first introduced in this country not many years ago by the late Dr. R. A. Smith, and the remarkable improvements since effected by Dr. Koch, there is every reason to hope that, with perhaps slight modifications, it may yet yield all the important hygienic results which all interested in sanitary science must ardently desire.

The following conclusions may be drawn from the preceding observations. 1. The total colonies found by culture in gelatine peptone do not represent the total actually present in a sample of water, but an indefinite aliquot part thereof. 2. The number of total colonies found does not, within a very wide range, justify the rejection of a sample; no more can a sample be relied on as safe if very few colonies only be indicated. 3. The test does not, as a rule, allow of distinction between pathogenic and harmless microphytes. 4. Pathogenic microphytes present in a sample of water are apt to escape detection by being crowded-out by the organisms ordinarily occurring in water. 5. The relative biological purification indicated by the test in samples of water after filtration through sand is at variance with other well-known facts, and should be accepted with caution.

CHARING-CROSS HOSPITAL.

A CASE OF SARCOMA OF THE LUNG FOLLOWING AMPUTATION OF THE RIGHT THIGH SIXTEEN MONTHS PREVIOUSLY; REMARKS.

(Under the care of Dr. POLLOCK.)

FROM the characters of the new growth in the lung in the following case, it is assumed that it was secondary to a primary growth elsewhere. The account which is given of the disease for which the limb was amputated does not mention the presence of anything of the kind as present then, but possibly the growth was very small in amount, and thus its existence was overlooked. It would be interesting to have a full account of the parts removed, with a history of the disease before amputation.

A. C——, aged seventeen, a timid, excitable, delicate-looking girl, was admitted on Oct. 25th, 1886. Her family history was faultless, and her own health up to fifteen years of age uniformly good. In June, 1885, after an illness of some months, she had her right thigh amputated at St. Mary's Hospital for suppurative arthritis following necrosis of the femur, due to periostitis. Her recovery was complete, and her health remained unimpaired until July, 1886, when she began to complain of pain in the left shoulder and left side of the chest. Frequent night sweats and gradual wasting followed. By the end of September she had become too weak to get about, and took to her bed. A week later cough developed, and soon after expectoration of a "dirty-looking phlegm" was noticed.

On admission the patient had a marked hectic flush. She was perfectly conscious, and of average intelligence. She complained of the pain before mentioned, and said that it was now constant, and increased by deep breathing or by any active movement. Her cough was sufficient to disturb her at night, and there was a little dark blood-stained sputum. The upper half of the left side of the chest was enlarged, and distended veins traversed its surface. The movements were diminished over the whole left side, and the prominent region just mentioned was practically motionless, nor could any vocal fremitus be obtained over it. The front part of the chest, from the apex of the lung to the heart, was absolutely dull; and the back, from the supra-spinous fossa to the middle of the scapula, gave a similar percussion note. Immediately below this the resonance was defective, down to the angle of the scapula; below this it was normal. The breath sounds over the greater part of the dull areas were almost inaudible, but here and there distinct bronchial breathing could be recognised. Lower down the breath sounds were weak, and at the extreme base normal. The voice sounds were diminished, but not high-pitched. The right lung was apparently healthy, its normal limits main-

Digitized by Google

tained. Nothing unusual could be detected in her voice, but on inquiry she said she had been unable to sing for two or three weeks. The left vocal cord was found to be stationary in the cadaveric position. The heart's action was fluttering, and the apex could not be accurately localised, but seemed to be displaced a little inwards. The sounds were clear. The pulse was weak, regular, and bilaterally symmetrical. The digestive tract and the physical signs of the abdomen were quite healthy. The pupils were equal, and reacted normally. The fundus of each eye was healthy. The pain was principally localised at the back of the shoulder and at the elbow. Distinct soreness and tenderness could be made out along the course of the brachial vessels and of the ulnar nerve. The urine was normal. An exploratory needle was passed into the swelling, but blood only was obtained.

The pain gradually increased in severity. On Nov. 3rd a difference was noted between the radial pulses, and on the 5th the left pupil was found to be slightly smaller than the right. On the 15th the left forearm and hand became œdematous. The other symptoms gradually increased, and during the next two months the patient became continuously weaker. The pain grew more intense, the enlargement increased, hard glands were felt above the clavicle, and the whole region became very tender; the inequality of the pupils was also more marked. On Dec. 30th numerous swellings scattered over the hairy scalp were noticed for the first time. They were circular and regular in outline, and varied in size from a hemp-seed to that of a small walnut. The swellings were tender, painful, rather elastic, and moved with the scalp. The patient thought they had been coming for several weeks. They were certainly not present on admission. On Jan. 14th she became restless and talked incoherently. Unconsciousness supervened at 2 A.M. on the 15th, and death occurred three hours later. Her temperature during the first month was uniformly maintained between 100° and 101°, but occasionally oscillated from 98° to 104°. During the last six weeks the range was from 99° to 100·4°. The physical signs remained unaltered in character, but gradually increased in extent.

Necropsy.—The upper lobe of the left lung extended across to the right side of the sternum, and consisted of a solid mass of new growth. Below this the heart was exposed as much as usual. The lower lobe of the lung was the healthiest part. The right lung contained many new growths, and there was half a pint of bloody serum in the pleura. The left lung was removed with much difficulty; the new growth in the upper lobe infiltrated the chest wall largely, and extended up into the neck between the scalene muscles, so as to press upon the brachial plexus and surround the subclavian artery. The arch of the aorta was also embedded in the mass, and several of the ribs were eroded. On section the upper lobe of the left lung was found to consist almost entirely of the mass of new growth above mentioned, which was degenerating in every part, and exhibited numerous cysts. One part at the anterior border was much harder than the rest, and was ossified or calcified to a slight extent. In the lower lobe there was one nodule the size of a Tangerine orange, soft and undergoing degeneration. The lower lobe of the right lung consisted in great part of new growth, which broke down on removal. Several smaller patches were scattered throughout the lung, most of them being soft, but one near the anterior border of the upper lobe was hard, and appeared to be ossified in about half its extent. The left leg had been amputated at the middle of the thigh. The stump was quite healed, and appeared to be some months old. Its end was swollen on the posterior aspect, and the swelling was very elastic and fluctuating. It was found to be a blood cyst. The bone was nicely rounded off at the end, and covered posteriorly by a thin layer of sarcomatous tissue. In the skin over the scalp were some half-dozen nodules of new growth, two of which had reached the scalp and penetrated it; one of them, close to the longitudinal sinus, had penetrated the bone to the dura mater, near which it was adherent. The brain was quite normal.

Dr. POLLOCK.—The nature of the growth in [illegible] was diagnosed very early. It was [illegible] was secondary, but it was difficult [illegible] of mischief. Had the leg been [illegible] this would have been plain. [illegible] effect could be obtained. [illegible] growth

commenced in the stump subsequently. Nothing beyond palliative treatment was available, and the poor girl was kept fairly free from pain by the use of morphia hypodermically.

LEICESTER INFIRMARY.

ABDOMINAL SECTION FOR INTERNAL STRANGULATION; FORMATION OF ARTIFICIAL ANUS; FAILURE OF PLASTIC OPERATION; ENTERECTOMY; CURE; REMARKS.

(Under the care of Mr. C. J. BOND.)

A. H——, aged twenty-two, was admitted on Jan. 7th with a history of intestinal obstruction lasting five days, coming on suddenly with pain in the hypogastrium and vomiting. The abdomen on admission was considerably distended, and peristaltic waves could be detected at times in the distended coils, though no localised swelling or tumour could be felt. The vomiting was feculent, and the patient's general condition very critical. Abdominal section was performed the same afternoon, by an incision large enough to admit the hand in the linea alba. After some search and the drawing out of a long length of contracted bowel, a fibrous band was found passing across between two contiguous surfaces of mesentery, and forming a ring, through which a coil of intestine had passed and become strangled; this band was divided between two ligatures, thus partially relieving the strangulation; the distended bowel, however, was very firmly adherent to, and dragged strongly down by, this band, at one point, and in gently separating the two the gut gave way,

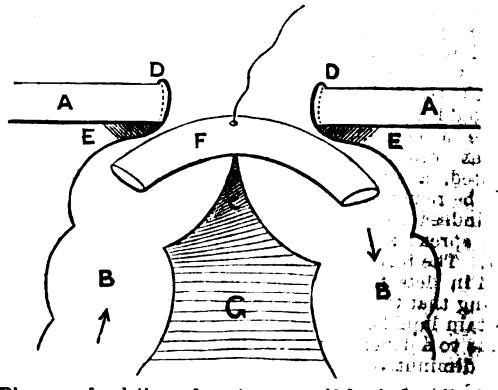

Diagram of relation of parts. A A, Abdominal walls. B B, Intestine. C, Spur. D D, Line of incision for plastic operation. E, Adhesions. F, Indiarubber tube. G, Mesentery.

some feculent fluid escaping into the peritoneum. As the gut seemed very distended and paralysed, and the opening difficult to close, the intestine, thoroughly freed, was drawn up to the upper angle of the abdominal incision; the opening in the bowel was then enlarged transversely across the gut, and a large quantity of feculent fluid and gas allowed to escape. The intestinal coils and peritoneum were then carefully sponged with warm boracic lotion, and the abdominal wound closed, except at the upper angle, where the mucous membrane was stitched round to the skin and a false anus formed.

The patient rapidly improved after the operation; there were no signs of peritonitis, and the abdominal distension soon subsided. It was soon found, however, as was suspected at the operation, that the opening was high up in the jejunum, and bile and semi-digested fluid food constantly poured from the opening over the abdominal wall and incision, excoriating the skin; yet it was remarkable that, with the exception of some ulceration round the stitches, the wound healed fairly well. The general wasting, however, was so rapid that on Jan. 15th, eight days after the operation, treatment by indiarubber tubes was commenced. A [illegible] rubber tube (see F in figure), with a string attached to its centre, was pushed into the intestine either up or down, until it could be slipped entirely within the gut, and then allowed to remain in position; tubes of various [illegible] were tried, but the best result was obtained [illegible] firm tube of four inches in length and [illegible] one inch, folded longitudinally while [illegible] opening and then allowed to expand; in [illegible]

Digitized by Google

and food were more or less passed onwards, though at times the tubes became blocked or displaced. As it was evident, however, that the opening under this treatment would not close, and the patient suffered from loss of nourishment and excoriation, an attempt was made to close it by a sort of plastic operation on Feb. 5th. An incision was carried all round the opening at the junction of the skin and mucous membrane, and carried down between the intestinal and abdominal walls, as seen in the dotted lines (D D); the freed edges of bowels were then inverted and their opposing outer surfaces carefully sutured by numerous interrupted catgut stitches, and the opening in the intestine thus closed by a more or less linear row of sutures; the abdominal walls were then slightly freed, and slid together and closed over the intestine. As the adhesions (E E) between the intestine and peritoneum were not divided, the peritoneal cavity was not opened. The patient was fed by injections, and for two days the parts looked well, but on the second day a little bile oozed through, the stitches soon gave way, and in a few days the opening was as large as ever. The indiarubber tubes were again introduced for a fortnight in order to allow the opening to get into a healthy condition, and the patient, who had become very emaciated, to gain strength.

On February 16th, having previously ascertained by the finger, introduced through the opening, the direction of the two portions of intestine and the extent of the spur (which was found to have been considerably reduced by the pressure of the tubes), the abdomen was again opened in the mid line, just above the artificial anus, and the finger introduced. In this way the extent of the adhesions of intestine to the parietal peritoneum was ascertained and found to be considerable, involving from an inch and a half to two inches of the intestine around the opening; the bowel was then carefully detached from the abdominal wall all round at the junction of the skin and mucous membrane, and the whole coil of intestine, some eight inches, freed and drawn out of the wound, the opening in the bowel being carefully closed between the fingers. The intestinal wall was seen to be much thickened and rough on the surface from divided adhesions. The opening extended transversely across the gut for three-fourths of its circumference, but did not involve the mesenteric border; it was large enough to admit three fingers. The contiguous lengths of bowel, passing to and from the opening (B B), were adherent and more or less parallel in direction; these were freed as much as possible, so as to bring the intestinal channel into a line. The old margin of the opening was now cut away with scissors, and the suturing commenced. The muscular coat being retracted by the finger-nail, the mucous membrane only was first united by a continuous silk suture in its whole extent; the muscular and serous coats were then inverted and their opposing peritoneal surfaces united by interrupted fine silk ligatures passed on each side through the two outer coats and then drawn together, an ordinary straight round sewing-needle being found most convenient. In addition some sutures were passed beyond the limits of the actual opening in the gut, which was thus firmly closed by about twenty or thirty closely placed stitches. The peritoneum was then carefully sponged, the coil of intestines returned free into the cavity, and the abdominal incision closed except at the upper part, where a drainage-tube was left in over the bowel, so that if escape occurred the fluid might find its way out of the peritoneal cavity. This afterwards proved important.

The operation lasted two hours and three-quarters. The patient was allowed nothing but water and opium for five days. Nutrient enemata were then commenced, and peptonised beef-tea was given by the mouth on the tenth day after operation. A discharge of pus occurred through the track of the drainage-tube on the second day after the operation, and on the fourth a little bile appeared. This occurred at intervals until the tenth day, when one of the silk intestinal stitches came away. The discharge now rapidly ceased, and the abdominal wound closed a few days later. The patient now began to take food, and rapidly increased in weight. No sickness occurred, and the bowels were moved by injection on the twelfth day. The temperature was generally subnormal throughout.

Remarks by Mr. BOND.—There are not, I think, many recorded cases of artificial anus in the jejunum formed by the surgeon in the middle line, and then treated by abdominal section and suture of the bowel. Most of the published cases have been secondary to strangulated hernia and situated in the groin, and the majority are examples of faecal fistula rather than artificial anus, in which the mucous membrane is continuous with the skin. No attempt was made in this case to close the opening in the bowel at the first operation, as it was thought that a free opening into the distended intestine would give the best chance of life. If called upon to treat a similar case, I should enlarge the opening in the intestine in the direction of the axis of the gut, and not across it, as, theoretically, that course, by keeping the intestine more in a line, should reduce the formation of the spur. The introduction of large-sized indiarubber tubes (suggested, I believe, by Mr. Banks) in cases such as this is a point of some importance. They appear to act in two ways: by their tendency to straighten after introduction they tend to prevent the excessive doubling of the intestine on itself opposite the opening, and by elastic pressure they reduce the projection of the inevitable spur; also by allowing the passage of bile and food into the intestine below they help to keep that in a normal condition and also sustain the patient. They seem to be especially applicable to cases of opening high up in the bowel, where the faecal matter is very fluid and the bile flow excessive, and should, I think, be introduced and worn if possible for some time before any operation for closure of the opening is undertaken. The plastic operation, which was really a turning in of the intestinal coats without freeing them from their adhesions to the abdominal wall, and was somewhat like that reported by Dr. Duncan in THE LANCET of July 5th, 1873, failed because there was too much tension on the intestinal walls. The last operation was undertaken with some anxiety, as the mortality according to Mr. Treves is nearly 40 per cent., but the patient unless relieved must have eventually died a miserable death from starvation. A great deal here depends no doubt on the way in which the sutures are applied, and it seems especially important to stitch the gut beyond the mere limit of the opening in order to firmly close in the puckers or gutters which are left at the angles. Doubtless, too, the fact that it was not necessary to divide the mesentery and so interfere with the blood-supply tended to a favourable result. It is also important to get the bowel into as direct a line as possible, thus reducing the angle or bend in the continuity of the tube. I think the slight escape of bile after the operation, with the throwing off of the intestinal stitch, must have been due to the fact that at one point the intestinal coat was very thin, having been injured in detaching the strong adhesions binding it to the abdominal wall; one more stitch worked its way out without any escape of fluid some three weeks after the operation. I should feel greatly obliged if any reader of this case would direct my attention to any list or statistics of cases of a like kind.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Inherited Congenital Deformity of Hands and Feet.—Psoriasis, Pityriasis, and Rheumatism.—Symmetrical Gangrene following Varicella.—Intussusception produced by a Tumour.

AN ordinary meeting of this Society was held on the 1st inst., Dr. W. H. Broadbent, President, in the chair.

Mr. R. W. PARKER and Dr. H. B. ROBINSON read notes of a case of Inherited Congenital Deformity of the Hands and Feet, in which a plastic operation had been done on the feet, the patient being a child aged three years and a half. The two inner toes were coalesced into a single great toe, and the three outer toes were similarly united into a little toe; the coalescence extended in part into the metatarsal bones, and there was a wide and deep cleft between. The operation consisted in removing the skin from the contiguous parts of the cleft, and then uniting the edges after the toes had been pressed together. A more shapely and sightly foot was thus obtained. The child was one of several who suffered from a similar deformity, and her mother, herself affected, feeling the inconvenience of such a foot, had taken her to the hospital to see whether something could be done to remedy the defect. The authors showed a family tree, from which it could be seen that the deformity affected three generations. The first to suffer was the child's grandmother, and of thirty-six lineal descendants sixteen were malformed; the malformation was perpetuated through the

Digitized by Google

female branches of the family. It was singularly uniform in its manifestations, and was attributed originally to a fright. The patient and several members of her family were exhibited.

Sir DYCE DUCKWORTH read a case of Psoriasis associated with Rheumatism, which passed into Pityriasis Rubra (Dermatitis Exfoliativa). F. A——, aged twenty-four, married seventeen months, mother of a child which she suckled for four months, was admitted into St. Bartholomew's Hospital on Nov. 14th, 1885. She was suffering from well-marked and ordinary psoriasis, which had lasted five months, and from rheumatic pains in most of the joints. Ten and five years previously she had had attacks of psoriasis, lasting four or five months, each accompanied with rheumatic symptoms, as at present. She lived at Stratford, on the ground floor of a damp house. The joint pains preceded the outbreak of psoriasis. When a child she had rheumatic fever. There was no known family history of rheumatic fever. She was a fairly well-nourished woman of slender build, complexion pallid, hair light-brown. The heart's apex was displaced outwards, and a systolic apex murmur was audible. Nothing was found amiss with any other viscera. Urine contained a trace of albumen. The whole body was covered irregularly with patches of scaly eruption, the erythematous areas around them being very wide. There was less of the rash on the face and neck, most on the abdomen. There was pyrexia, temperature varying from 100° to 103·8° during her stay in hospital, with nightly rises. The digestive system was not much disturbed. Urine acid; sp. gr. 1023; it contained very often a trace of albumen, and sometimes abundant urates. Catamenia regular since the birth of her child. At the time of admission to hospital the psoriasis was beginning to pass into a general desquamative dermatitis, and rheumatic symptoms were increasing in severity. Milk diet was ordered. To have an alkaline bath on alternate nights, and olive oil to be rubbed in all over the body. Fowler's solution in four-minim doses in an alkaline tonic mixture was given thrice daily. The appetite increased under this treatment. The pain grew worse, and the temperature kept up. Effusion occurred in some joints. Sodium salicylate was next given to the extent of a drachm daily. Soap-and-spirit lotion was used to remove the hard scales from the scalp, and linimentum calcis to the body generally. No improvement followed from the salicylate treatment, and the temperature was unaffected by it. The skin was now universally affected, and cast off handfuls of scales. The rheumatism was severe, and the patient became very ill. She begged for meat and for better diet than was thought fit for her. The salicylate was increased to eighty grains each day, and sitz baths given instead of alkaline ones. Joints of legs and arms very painful. Hypnotics required at night. In the third week after admission, the plans of treatment hitherto having been unavailing, a change was made, the quino-alkaline draught being given, and oleate of zinc ointment applied. Mashed potato and custard pudding added to diet. The skin improved somewhat after this, but still desquamated freely. Temperature still pyrexial. Joints improved. No fresh cardiac troubles came on, but "hæmic" basic murmurs developed. Within ten days the morning temperature began to reach normal, but the evening rise was nearly 102° on several occasions. On Dec. 11th arseniate of sodium in fifteen-minim doses was begun, and full meat diet was given. In a few days there was very decided improvement in respect of the skin and joints, but the temperature continued high, reaching its highest point, 103·8°, three nights after beginning this treatment. Antipyrin was given in full doses without any effect on this. The pulse was 138. Appetite very good. The arsenic was increased gradually up to ten minims at each dose. At the end of December patient's skin was getting clear, joints improving, and she got out of bed daily. Starch and zinc paste was found useful for the skin at this time. In January the joints were painless, but ached when fully stretched. The wrists and fingers were deformed, joints knotty, and fingers turned out to ulnar side of arm. When the patient left the hospital on Feb. 12th the skin was perfectly smooth and natural. The joints of the wrists and hands were crippled and deformed. The case illustrated the transformation of psoriasis into diffuse exfoliative dermatitis, an occurrence which has been previously noted. The relation of the rheumatic disease, if it was rheumatic, was of interest. Psoriasis is not uncommon in persons rheumatically disposed, especially in subjects of rheumatoid arthritis. The powerlessness for good of the salicylate treatment was noteworthy. The same has been noted of this drug in chronic rheumatic arthritis and so-called gonorrhœal rheumatism. The benefit of full arsenical medication was most marked, and no relief was afforded by treatment which commonly proves useful in ordinary rheumatism. The author had not found dermatitis exfoliativa rebellious to treatment by alkaline tonics, baths, and oily inunctions.—Dr. RADCLIFFE CROCKER said that his experience also testified to the possible connexion of rheumatism with a previous dermatitis. He thought that any form of dermatitis might be the antecedent—e.g., excessive inunction of chrysarobin had been recorded as preceding pityriasis. A case was narrated of nine attacks of psoriasis. The ninth attack was followed by pityriasis; each subsequent attack was also followed by pityriasis, and the patient died after the fourth attack. There was a mitral murmur, but no definite history of rheumatism. A case of a woman suffering from lichen ruber was also related. In this there was also rheumatism with mitral disease. Hypodermic injections of arsenic were followed by improvement. The rheumatism became worse; pericarditis and iritis developed. The lichen ruber element shelled off in large plaques, and pityriasis developed. Salicylate of soda and a low regimen effected no good, but the administration of quinine and good food was followed by improvement. Nothing but calamine liniment was used for the skin. The heart murmurs alone remained. The lichen ruber returned in very slight degree. Psoriasis was the most common antecedent of pityriasis rubra when this did not occur as the only disease.—Dr. T. BARLOW had also observed the triple association of psoriasis, pityriasis, and rheumatism. The case of a gentleman was related. A mitral murmur with hypertrophy of the left ventricle existed. During the last two years the type of the skin affection had altered. The patient developed an acute attack twice a year. At the beginning of one of these Dr. Barlow first saw him. There was some brawny induration of the true skin as well as the psoriasic condition. The attack lasted one month, and was attended with fever and much general illness. Anorexia was a marked symptom. The skin symptom changed, and a bright-red, swollen skin developed, with lymphatic glandular enlargements. After complete exfoliation of the cuticle the skin was left soft and supple, like that of a new-born child. He had watched five or six attacks in the same gentleman. He agreed that when once the skin lesion had taken on this type it would continue. During the attack certain conditions about the joints might have been regarded as rheumatic, but there was no true effusion into the synovial cavities.

Mr. EDWARD BELLAMY read a case of Symmetrical Gangrene (Raynaud's Disease) following Varicella in a child aged four, causing death on the fourth day. The patient was admitted under his care on Jan. 19th, 1887. On admission, she had spots of varicelli over her body and face, which were first noticed on the 16th. On the evening of the 19th, at 7 o'clock, the child complained of her right leg being sore, and a small circular black patch about as large as half a crown was seen below the inner side of the knee; by 10 o'clock this patch had extended down the leg to the foot, when she was brought at once to the hospital. On arrival, a similar patch had made its appearance just above the left ankle, which rapidly extended up to the knee. The patient was unable to stand, and complained of great pain in both legs, which increased on pressure. The second, third, and fourth toes of the right leg were exempt from discolouration, and the fifth but slightly mottled. Shortly after admission, an oblong patch about 2 in. by 2 in. appeared on the outside of the left thigh. On the 21st a small patch appeared on the outer side of the right forearm, and slight discolouration on either side of the spine, on a level with the crest of the ilium, and in the afternoon of the same day in either cheek and conchæ of both ears. The complexion was very white, face sallow, expression dull and heavy; tongue dry and brown, but reddish at tip. Pulse 150, weak; temperature 100°. Heart sounds normal; breathing normal; both legs cold and insensitive; pulsation in left femoral fairly distinct, but could not be felt in right. Urine: sp. gr. 1023; clear and pale; no trace of albumen and no hæmoglobin could be detected. In the evening of the 21st she was suddenly seized with stertor and died. A full account of the post-mortem accompanied the paper. Perhaps the most interesting points are as follows:—There was an enormous opening in the foramen ovale, bounded below by a valve a quarter of an inch deep, having a free crescentic margin. Dissection of the right

Digitized by Google

leg: The fat and skin and gangrenous parts were dark-purple from hæmorrhagic infiltration, this appearance fading away at the apex of Scarpa's space. The obvious gangrene ceased just above the inner condyle, the skin above being apparently normal. The leg, which appeared quite gangrenous, was of a uniformly purple colour. There were some petechiæ or small hæmorrhages in the intermuscular plane, the muscles themselves being very strongly contracted in rigor mortis, and appearing almost healthy. Here and there they showed small hæmorrhages; this was especially the case in the deeper fibres of the soleus. The femoral glands were a good deal enlarged, and either hæmorrhagic or containing a quantity of blood pigment. The saphena vein contained only post-mortem clot.—Mr. J. H. MORGAN said that the most remarkable point was the circumstance that the gangrenous condition extended higher on the inner side than on the outer. The gangrene did not spread much whilst the child was in the hospital. The great toes remained perfectly normal. At the necropsy the rigor mortis was well marked. The hæmorrhages were apparently confined to the cutaneous structures. The vessels were found to be healthy.—Mr. COODE ADAMS suggested that the case might have been one of hæmorrhagic small-pox; he inquired as to the condition of the body temperature.—Dr. LONGHURST considered that the case was due to blood poisoning, and he thought that it might have been small-pox.—Dr. HERRINGHAM regarded the case as most likely one of varicella gangrenosa, a condition which was not so very uncommon.—Dr. BENHAM asked whether the child had been exposed to cold, for the appearances were something like those of frost-bite.—Dr. RADCLIFFE CROCKER asked how the gangrenous area developed, whether in connexion with the varicellar vesicles or separately. He said that the condition was not allied to ordinary cases of varicella gangrenosa. Were the patches on the cheeks or arms pure hæmorrhages or gangrenes?—Dr. T. BARLOW said that all the cases of varicella gangrenosa he had seen began in the varicellar bullæ; it was a multiple gangrene quite different from the case now described. Again, there was no resemblance to symmetrical gangrene or Raynaud's disease. He classed Mr. Bellamy's case along with those of symmetrical gangrene following the acute specific fevers. He had recently seen one case, not so extensive, of symmetrical gangrene after measles. In these cases a dissolutio sanguinis appeared first to occur and to be associated with hæmorrhages as the initial phenomenon of the gangrene. In Mr. Bellamy's case, besides the hæmorrhages in the skin, there were extravasations in the pleuræ and muscles. In other cases, also, he had seen the diffuse hæmorrhages occurring in various organs. The tips of the ears was a favourite site. He could not but think, in opposition to Mr. Morgan, that the heart condition—for the foramen ovale was large enough to admit the thumb—may have had some share in the causation of the hæmorrhages. In one case huge hæmorrhages developed around the measles papules in a child who was the subject of congenital heart disease.—Sir DYCE DUCKWORTH believed that congenital heart disease was a serious complication of the exanthemata. He would not have thought of varicella gangrenosa in connexion with the case narrated.—Dr. BROADBENT agreed with the views of Dr. Barlow. In a case recently seen of typhoid fever, both ears became gangrenous, but he could not say whether preceded by a hæmorrhage; one or two fingers of each hand were also affected. He said it had no kind of resemblance to hæmorrhagic small-pox, of which he had seen some thirty cases.—Mr. BELLAMY briefly replied.

Mr. ARBUTHNOT LANE described a case of Intussusception produced by the presence of a Tumour growing from the Mucous Membrane of the Transverse Colon. After an attack of diarrhœa, in a chronic case of hip-joint disease in a child aged eight, a tumour as large as a walnut was found projecting from the anus. It was much congested; blood oozed from its surface. The nurse in attendance supposed it to be a prolapse of the mucous membrane of the rectum, and attempted to return it within the anus, but was unsuccessful. On examination, the tumour appeared to have a very long pedicle, which gradually increased in thickness, extending beyond the reach of the finger. As there were no symptoms of strangulation, and as the length of the pedicle was doubtful, he returned the tumour within the rectum. It soon passed out of reach. On the following day the tumour could be felt in the middle line, between the umbilicus and symphysis, between the finger in the rectum and the hand on the surface of the abdomen. Some days after, during another attack of diarrhœa, the tumour was again extruded from the anus. On this occasion it was found that the tumour was sessile, and that it was attached to the very congested mucous membrane by a constricted neck, the prolapse of gut being abundant and lax, so that on the first occasion the whole of the thin apparent pedicle must have been formed by mucous membrane and the intestine itself. On the removal of the tumour, the prolapsed gut was readily replaced above the pelvic brim by the finger, and subsequent examination revealed no signs of an intussusception. No tumour could be felt in the abdomen on either occasion in which the growth projected from the anus.—Mr. F. TREVES said that the mildest cases of intussusception were often those associated with large polypi in the colon. Polypi were present in 5 per cent. of the cases of intussusception. The first symptom of such intussusception was often the appearance of the tumour at the anus. He also drew attention to the causational influence of a mass of epithelioma in the wall of the bowel as leading to the formation of an intussusception.—Mr. A. E. BARKER said that the number of cases in which epithelioma had been the cause of intussusception was not great. He briefly related a case of epithelioma of the sigmoid flexure, in which the new growth extended two-thirds round the circumference of the bowel, and led to intussusception. The pedicle of the tumour was formed of the coats of the bowel itself.—Mr. BRYANT thought that intussusceptions caused by tumours were not very rare, though in the adult they were not recognised sufficiently. He believed a fair proportion of the cases in adults were due to tumours. He had recently operated on a lady aged eighty-four for intussusception. There was a tympanitic abdomen, and a long history of bowel trouble, followed by acute obstruction. Examination per rectum detected a growth in the bowel, which occupied the centre of the canal itself. The growth was as large as an egg, and of coarse villous nature. Its removal was easily effected, and the bowel then soon ascended above the brim of the pelvis, giving the palpating hand a curious sensation. The lady soon became well, and walked about in perfect health. The fact that the growth could be felt was the interesting point in Mr. Lane's case.

The following living specimens were exhibited:—Dr. Drewitt: A Case of Lupus, treated partly by Salicylic Paste, partly by Scraping. Mr. Parker and Dr. Robinson: Inherited Congenital Deformity of the Hands and Feet; Plastic Operation on the Feet.—Mr. Walsh showed for Mr. E. W. Parker an Abdominal Tumour (? renal sarcoma) in an infant aged two years.

MEDICAL SOCIETY OF LONDON.

Ulcerative Endocarditis.—Alleged Dangers of Starch-containing Foods during the period of Infancy.

AN ordinary meeting of this Society was held on Monday last, Dr. J. Hughlings Jackson, F.R.S., President, in the chair.

Sir DYCE DUCKWORTH read a case of Ulcerative Endocarditis that simulated typhoid fever and acute tuberculosis. It occurred in a girl aged twenty, in whom there was no history of rheumatic fever, but some of the joints had been slightly swollen. A systolic murmur was detected in the mitral area after the patient had been admitted into hospital. Cough, with bronchitis, wasting, and loss of power, with other symptoms of the typhoid state, were present, but there were no spots or diarrhœa and no enlargement of the spleen below the ribs. The necropsy revealed no tubercles or splenic infarctions, but the mitral valves were much diseased and fungating.—Dr. SANSOM inquired whether it was possible for the pneumonia to have preceded the malignant endocarditis. Dr. Osler, and a pupil of M. Cornil's, had drawn attention to the relationship between pneumonia and ulcerative endocarditis. He referred to the case recorded in the Medical Society's Transactions. Variability of murmurs was an important sign of this form of severe endocarditis. The case improved immensely under the use of half-drachm doses of sulpho-carbolate of sodium. She subsequently died, and the necropsy seemed to show that a fresh eruptive process had supervened whilst the original disease had subsided. The progress of the temperature afforded no aid in diagnosis.—Dr. HUGHLINGS JACKSON said that this form of endocarditis was met with in some cases of epidemic meningitis. Absence of knee-jerks would point to meningitis in a case of doubt between meningitis

Digitized by Google

and typhoid fever.—DR. HENRY WHITE dwelt on the difficulty of diagnosis.—Sir DYCE DUCKWORTH said that the antiseptic treatment had proved valueless in his hands. He had seen the knee-jerks disappear at the close of cases of typhoid fever.

MR. E. W. PARKER read a paper on the alleged Dangers of Starch-containing Foods during the period of Infancy. As the result of many years' observation at the East London Hospital for Children and in private practice, he stated his belief that the dangers of starch foods were greatly exaggerated. He was quite aware of the mortality among artificially-fed children, but he attributed this, as well as the marasmic condition of many that did not actually die, to congenital debility, the result of debilitating influences of various kinds acting on the parents before the birth of the children. An analysis of cases had convinced him that, in a large proportion of cases, artificial food was only commenced because the children were weak and puny, and not thriving on the breast milk. Mr. Parker did not advocate artificial feeding, nevertheless, but the contrary. He rather implied a belief that artificial feeding was on the increase, and that it had the consent of the medical profession: many mothers left off suckling, he argued, without sufficiently good grounds, so widespread was the doctrine that if all the starch had been converted into dextrose, and so rendered digestible, artificial feeding might safely be commenced. This was quite an error, and, moreover, it was desirable that mothers should nurse their children, as nursing mothers were less liable to conceive, and thus there was a longer interval between the children. Too rapid child-bearing was one result of not suckling; it was very debilitating, and one of the most potent sources of the marasmus and weakliness so largely present among the children of the poorer classes. Besides this, a child that was deprived of the mother's milk was probably deprived of the mother's care, not less important than the milk for a weakly child. Thus, Mr. Parker argued, there were many factors to be taken into consideration in estimating the causes of marasmus and its consequences. He thought that too much stress had hitherto been laid on the effects of artificial feeding, and more especially on the starch constituents of this food, and that too little stress was laid on the congenital debility of children born under adverse circumstances.—DR. GIBBONS did not agree with the conclusions of Mr. Parker on the innocuous influence of starch in infancy. Imitation of the mother's milk was the object to be aimed at in artificial feeding.—DR. ALLCHIN admitted that defective hygiene was a most important consideration, but he did not agree that starch was not injurious.—DR. DE HAVILLAND HALL said that puppies had developed rickets as the result of being fed on biscuits.—MR. R. W. PARKER, in reply, said that the experimental observations on animals were valueless *quâ* the point under discussion, because of the bad hygienic circumstances under which the animals were kept.

DR. WHIPHAM read a paper and showed some drawings of cases of so-called Glossitis Migrans, Wandering Rash, Lichenoid Eruption. A case in a domestic servant suffering from mitral disease was narrated. The second case occurred in a young man who suffered from typhoid fever. The sinuous margin was composed of vast accumulations of epithelial cells, taking the shape of a Chinese pagoda. The tissue of the mucosa showed evidence of inflammatory growth. Dark opaque masses overlaid the epithelium in places, and were probably composed of colonies of micrococci. He supported Lemonnier's view, that the lesion was a superficial inflammation—a glossitis superficialis migrans.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

AT a meeting held at 11, Chandos-street, Cavendish-square, on Wednesday, March 9th, Inspector-General Lawson in the chair,

DR. STEPHEN MACKENZIE read for Dr. Wykeham Myers a paper entitled "Further Observations on Filaria Sanguinis Hominis in South Formosa," of which the following is an abstract. The author stated that further and extensive careful examination had failed to discover in South Formosa a mosquito like the Amoy filaria-nurturing variety, either in species or capacity for nursing the blood embryo. He then proceeded to describe the varieties of mosquitos he had been able to discover in South Formosa, appending sketches and careful measurements of the tiger, brown, and ejecting mosquitos, with sketches and measurements of the Amoy filaria-nurturing mosquito, and reiterated his opinion that the absence of filarial diseases in South Formosa is due to the absence of the species of mosquito which is capable of acting as the intermediate host to this parasite. He next discussed the ultimate destination of the filaria embryos found in the blood, and the following are the conclusions at which he arrived:—1. Accepting that parturition in the parent worm is continuous and exceedingly prolific, then removal of those filariæ which have had their chance of mosquito withdrawal, but have escaped detection is necessary, in view of the swarm which will inevitably enter the blood from the lymphatic system at the next period of its suitability for their reception. 2. The marked difference between the condition of that fluid when favourable for filarial development and its state when hostile to their existence seems due either to the *presence* of an excessive amount of carbonic acid, *or* the *absence* of a sufficient quantity of free oxygen. Inasmuch as the former necessarily involves the latter, and experiments seem to show (*a*) that direct contact of carbonic acid in presence of excess of oxygen is not, immediately at least, injurious, but that (*b*) exclusion of oxygen, either by surrounding the blood with carbonic acid or placing it in a condition opposed to access of the former gas, brings about the destruction of the parasites, and that (*c*) the behaviour of the filarial embryo, both in the human blood and when contained in the mosquito, seems strongly to indicate a desire for this gas, it may be assumed that probably its presence is essential to further development, and its withdrawal or diminution in quantity conducive to death. The author therefore suggested the following as the course pursued by the embryo from birth until its absorption by the mosquito. For a period of not less than twelve hours, and probably in no case exceeding twenty-four, the filariæ remain in the lymphatic system; at some time during this period, urged by the favourable conditions in the hæmic circulation, it exhibits for the first time a selective ability, and enters the latter. It will be observed that, supposing twelve hours to be the least time apportioned for intra-lymphatic existence, and that the filariæ disappear from the blood at 7 A.M., appearing again at 7 P.M., all those born between these hours will be ready for entrance into the blood at various times during the following night, but those born during the night itself would only be fitted for intra-vascular existence at some time during the day. This infers a longer or shorter delay, according to the hour of birth, and may account for the fact of embryos being occasionally seen in the blood during daylight, as was the case with all Manson's early finds, got as they were during that period. It is possibly, however, more or less the result of accident, due either to what we may call impulsive injudiciousness on the part of a few, or untoward subjection to the irresistible forces present at or near the termination of the thoracic duct, within the scope of which they have been tempted to approach too closely. As to the facility for postponing their advent shown by those embryos born during the night, we have actual proof of such capability on the part of the parasite, in those geographical results previously described. The term "postponement" is only used in a figurative sense. Although, as before pointed out, the embryos are wanting in locomotory power at this stage, still there can be no doubt of their ability to resist moderate onward pressure, either by actual adhesion or by the opposition of forces resultant from the contraction and extensions in the body; converging as these do towards a central point, they are able to control within limits the duration of their stay in the sluggish lymph current. When the proper time arrives, however, they yield to the pressure, and their passage to the now attractive blood is brought about. In the mosquito, where migration has to be effected in a stagnant medium, inherent locomotory powers are required, so at or about the end of another twenty-four hours the embryo temporarily becomes possessed of this ability, moving about freely. Arriving at the thorax, and beginning at a stage where quiescence is more comfortable to its necessities, the parasite seems again to enter on a sort of chrysalis state, or, in other words, to become passive. The last section of the paper dealt with the pathology and treatment of elephantiasis or lymph discharges. The author discussed in great detail the different views put forward by various writers. Agreeing with Manson as to the filarial origin of these diseases in the majority of instances, he differed from him as to the mechanism by which the filariæ operated. He rejected abortion of the parent worm, and

Digitized by Google

was inclined to attribute the overgrowth of tissues, discharges of lymph or chyle, and febrile manifestations to overgrowth of cells due to increased plasmic flow (as distinguished from obstruction), due in the first instance to the presence of filaria sanguinis hominis (or in non-filarial cases to an ulcer, eruption, &c.), or some other excitation, and which, when once set up, might persist after the original exciting cause had ceased to operate. With regard to treatment, he advocated, when practicable, removal from a filarially infected region, but where this could not be accomplished filtering and boiling all water drunk, and for local treatment pressure both on the affected part by indiarubber bandages and over the arteries supplying the region, in preference to deligation of arteries. In connexion with the paper, Dr. Stephen Mackenzie exhibited a patient suffering from chyluria contracted in India, and demonstrated the living filariæ in the blood.—In the discussion which followed, Inspector-General Lawson, Drs. Thorne, Mortimer Granville, and Willoughby, and Mr. Smyth took part.

ACADEMY OF MEDICINE IN IRELAND.

The Marsupial Heart.—Absence of the Internal Iliac Artery.

A MEETING of the Sub-section of Anatomy and Physiology was held on Feb. 10th.

Dr. CUNNINGHAM exhibited the Heart of a Kangaroo which he had recently successfully injected. He stated that Owen was of opinion that the marsupial heart was distinguished by (1) the absence of the fossa ovalis, (2) the presence of a cleft in the auricular appendix of the right side, and (3) the absence of a separate orifice in the right auricle for the coronary vein. The absence of the fossa ovalis was also associated with a total absence of the ductus arteriosus, the Eustachian valve, and other vestigial remains of embryonic life, such as the urachus, hypogastric arteries, round ligament of the liver, &c., and was accounted for by the short period which the embryo spent within the uterus. The bifurcation of the auricular appendix was well seen in the specimen exhibited, and it was present in a marked form in the phalangers, but was absent in the thylacine and dasyure. With regard to the third point of distinction mentioned by Owen, Dr. Cunningham stated that he had been able to make out in the *Challenger* marsupials a separate opening of the great cardiac vein in the right auricle, but this was situated at the upper part of the cavity close to the opening of the superior vena cava.

Dr. LEDWICH read notes of the dissection of a male subject, in which the Internal Iliac Artery was absent on the left side. On the right side the structures were normal. The abdominal aorta bifurcated at the lower border of the third lumbar vertebra to form the two common iliac arteries; the right divided normally into the internal and external iliacs, but the left, instead of dividing, continued as a single vessel in its whole course to the femoral artery. This single iliac artery passed obliquely downwards and outwards over the psoas muscle for a distance of three inches, and then, turning somewhat sharply inwards and then downwards over the ilio-pectineal line, entered the pelvic cavity. This intra-pelvic portion of the vessel formed a long loop reaching to a point about half an inch below the highest part of the great sciatic notch. The artery then, ascending, recrossed the ilio-pectineal line, and, turning downwards over the horizontal ramus of the pubes, terminated in the femoral artery. This vessel may therefore be considered as divided into three portions—1, the oblique portion; 2, the looped portion, which may be subdivided into (*a*) the descending limb, (*b*) the transverse part, and (*c*) the ascending limb; 3, the horizontal or pubic portion. The diameter of the vessel was greatest at the transverse part of its loop, where it measured seven-sixteenths of an inch; and least at the termination of its pubic portion, where it measured five-sixteenths of an inch. Its total length was nine inches. The first sacral nerve passed through the loop of the artery from without inwards, and tightly held down the vessel; the nerve then, winding round the inner side of the ascending limb of the loop, joined with the lumbo-sacral cord. The branches which arose from each portion of the artery were as follows:—From the oblique portion: (1) A posterior ilio-lumbar artery of some size, which resembled in its course and mode of termination the lumbar branch of a normal ilio-lumbar artery. (2) Two or three small branches to the psoas muscle, peritoneum, &c. From the descending limb of loop: (1) The internal pudic artery arose opposite the first sacral foramen. Its intra-pelvic portion was exceedingly long, measuring from its origin to the great sciatic notch fully five inches, and in diameter it measured slightly over an eighth of an inch. From its origin the pudic artery curved inwards and downwards to the middle of the anterior surface of the bodies of the third and fourth bones of the sacrum, where it gave off the middle sacral artery. It then curved outwards and downwards, between the second and third sacral nerves, and in front of the pyriformis muscle, to the great sciatic notch, through which it passed below the muscle, and followed thenceforth the route and termination of a normal pudic vessel. The middle sacral artery was very small, and arose from the internal pudic over the fourth bone of the sacrum. It passed downwards in the middle line for a distance of an inch and a half, and terminated normally on the coccyx. The internal pudic also gave off, just outside the sciatic notch, a large muscular branch to the gluteal muscles. From the transverse part of loop: (1) The lateral sacral artery arose just above the second sacral foramen. It was a short small vessel, and sent branches into the second and third sacral foramina. (2) The gluteal artery was a short thick trunk, which arose from the junction of the transverse and ascending portion of the loop. It passed almost directly outwards through the great sciatic notch above the pyriformis muscle and terminated in the usual manner. From the ascending limb of loop: (1) The sciatic artery arose three-quarters of an inch above the transverse portion, and, passing downwards internal to the first sacral and the lumbo-sacral nerves, left the pelvis through the great sciatic notch below the pyriformis muscle, and terminated in the usual way; (2) an anterior ilio-lumbar artery (much smaller than the posterior), which terminated like the iliac branch of a normal ilio-lumbar artery. No other branches could be discovered arising from this abnormal iliac artery. The obturator and deep epigastric arteries arose by a common trunk from the femoral, about one inch below Poupart's ligament.

Dr. BROOKS communicated the result of his investigations into varieties in the Innervation of the Umbricals of the Hand and Foot, with some observations on the perforating flexors.

Dr. CUNNINGHAM exhibited (1) four Chinese Plates of Human Anatomy which had been presented to him by Dr. Irwin of Tientsin; and (2) casts of Deformed Feet of Chinese Women which had been presented to him by Professor Welcker of Halle. He explained from the casts that the foot was bent into an exaggerated arch so that the os calcis was brought to lie immediately below the astragalus; but, though they distorted the foot, the Chinese seemed to have an appreciation of the importance of the great toe, which was preserved for locomotion.—Dr. FRAZER said he had a book with a series of plates published two hundred years ago, illustrating the Chinese system of anatomy, which had been followed for upwards of a thousand years.—Mr. THOMSON remarked that they had advanced in surgery of late years. They had had "Erichsen's Surgery" translated into Chinese.—Dr. FRAZER: And also a Dublin book—"Churchill's Midwifery."

CAMBRIDGE MEDICAL SOCIETY.

A MEETING of this Society was held on Feb. 4th, when the President (Dr. Bradbury) gave an address on resigning the chair, to which Mr. Cleaver was afterwards elected. The chair was taken by the Vice-President, Mr. Stear, M.R.C.S., and the following communications were made:—

Quinsy.—Dr. EASBY (Peterborough) read a paper on quinsy and its treatment. After speaking of the old method of antimonials, free purgation, complicated gargles, leeches and blisters, Dr. Easby advised the use of aconite given after Dr. Ringer's method, or from ten to fifteen grains of salicylic acid or salicylate of soda given every two hours, which had invariably afforded speedy relief. Gargles were strongly condemned as both useless and cruel to the patient. As a local application, a powder consisting of equal parts of tannin and iodoform puffed on to the swollen tonsils he had found give great relief to the pain.—Dr. LATHAM agreed that gargles were useless, and advised the use of the spray, chlorine water

Digitized by Google

or some antiseptic. It was especially useful for children. He strongly endorsed Dr. Easby's remarks on giving salicylic acid and salicylate of soda in the early stage, more especially if there was any association of rheumatic symptoms.

Note on Stellwag's Symptom.—Mr. WHERRY showed a patient, a married woman, aged thirty-two, who came to Addenbrooke's Hospital with marked retraction of the left upper eyelid (Stellwag's sign). There was no proptosis or goitre, but some throbbing of the carotids and palpitations; no cardiac bruit. She blushed and perspired very easily, and suffered a good deal from indigestion and sleeplessness. The retraction of the lid was extremely well seen when the eyes looked downwards. There was no want of consensual downward movement of the eyelid (Graefe's sign). The pupils were equal and active, V=$\frac{6}{6}$ in both; fundus normal; no pulsation in the retinal vessels; complete power of closing the eyelid; cornea and conjunctiva sensitive. The patient has been married thirteen years; had no miscarriage; has one child, now six years old; has had no illness of late; menstruation quite regular, rather scanty; occasional leucorrhœa. Although there was no exophthalmos or goitre, Mr. Wherry thought this was probably a case of Graves' disease. This patient had first noticed something wrong with her eye about a year ago. She had been under observation for the last six months, and had improved under treatment by bromide draughts at night and small doses of belladonna twice daily. There was little change, however, in the eyelid symptom, which came on rather suddenly and continued to the present. Mr. Wherry wished to draw attention to this symptom without suggesting any theory as to the pathology of Graves' disease, because the opinion has been expressed by Graefe that cases are not rare in which the only symptoms of this affection in women are rapid action of the heart without hypertrophy or valvular disease and defective mobility of the lid; the latter is, at any rate, an extremely important symptom to take note of—important in the diagnosis, treatment, and pathology of Graves' disease.

Intra-uterine Amputation of Forearm.—Mr. STREET said that A. B——, aged twenty-two, a healthy young woman, was first seen by him when suffering from inflammation of the left olecranon bursa. From an inch below the elbow the limb is wanting, and the stump presents all the appearances of an intra-uterine amputation. On inquiry he found that she was born with this deformity; the stump was quite healed at birth, and no evidence of any remains was to be found. The cicatrix is very small, being only three-quarters of an inch long, and the skin is very little puckered around it; it is not adherent to the deeper parts. The bones of the forearm can both be distinctly felt, and the olecranon seems almost equal in size to the right one. The humerus and muscles of the left arm are no smaller than can be accounted for by not being so much used as the right arm. There is no history of syphilis in the mother nor was any accident remembered during gestation.

Immature (Senile) Cataract.—Mr. DEIGHTON read a short paper in which he discussed the conditions which rendered it advisable to operate in cases of immature (senile) cataract; he also read notes of a case in which he had operated, the patient obtaining V=$\frac{6}{6}$ and 1 Jaeger.

Reviews and Notices of Books.

A Text-book of Pathological Anatomy and Pathogenesis. By ERNST ZIEGLER. Translated and Edited by DONALD MACALISTER, M.A., M.D. Part II.: Special Pathological Anatomy. Sections IX. to XII. London: Macmillan and Co. 1886.

WITH this, the third, instalment of by far the best appreciated pathological text-book of our day, Dr. MacAlister has completed the task to which he applied himself. Of the remaining sections of the original work, some are not from Professor Ziegler's pen, and Dr. MacAlister has decided not to translate them. These sections, it may be said, comprise the diseases of the organs of special sense, of the osseous and muscular systems, and of the organs of generation. Some at least of these subjects would have been welcomed by the English reader, who may regret the decision to exclude them. Our literature is not so rich in detailed exposition of the pathology of these organs and tissues but that we could gladly receive them, and we may express a hope that the translator, whose duty has been so admirably performed in the portions he has published, may yet reconsider his resolve, and add a fourth volume, which will complete the work.

The volume before us deals with the important subjects of diseases of the urinary, respiratory, and nervous systems. They have been carefully edited, for the bibliographical references, which form so useful and notable a feature, are thoroughly up to date, rendering the work one of great value to the pathological investigator. The text is remarkable for the lucidity and scientific treatment of subjects which have been more or less obscured by different writers, who have dealt with them from too narrow a standpoint. Take for example the subject of renal disease, which since the time of Bright has been a field of so much contention. A sharp distinction is drawn between the simple "contracted" kidney and "renal cirrhosis." The former is demonstrated to depend upon arterial changes, a condition of atrophy due to arterio-sclerosis. It is the form which occurs in chronic lead poisoning, and it is allied to senile atrophy. We have here a recognition of the views promulgated by Sir W. Gull and Dr. Sutton, but, as Professor Ziegler points out, this is not the sole form of granular kidney known. Contraction of the organ may be an ultimate stage of chronic parenchymatous nephritis, or it may be the outcome of a true cirrhosis or a "chronic indurative nephritis," in which fibrous over-growth is the predominant feature. This teaching seems to harmonise the divergent doctrines on the nature of chronic Bright's disease in a more satisfactory manner than the attempt to create a unity in nature and origin between diverse forms of disease, which have nothing in common but the feature of wasting of secreting structure. The various types of nephritis — hæmatogenous nephritis is the term here employed—are differentiated into three groups: 1st, acute; 2nd, chronic parenchymatous; and 3rd, chronic indurative. Under the first head are included: 1, acute glomerular nephritis, such as is characteristic of scarlatina; 2, acute diffuse nephritis or acute inflammatory œdema; 3, acute disseminated interstitial nephritis, which is regarded as the commonest form of acute renal inflammation; and, 4, disseminated suppurative nephritis, which in this country we know best under the unfortunate name of "surgical kidney," but which includes also all metastatic and embolic abscesses. Of chronic parenchymatous inflammation, characterised by intertubular exudation as well as alteration in the epithelia, Professor Ziegler distinguishes according to their stage the following: 1, inflamed fatty kidney; 2, large mottled kidney; 3, large white kidney; 4, chronic hæmorrhagic nephritis; 5, chronic glomerular nephritis—a subdivision which is justified on anatomical if not on clinical grounds. Of the chronic indurative form, or renal cirrhosis, we have spoken above. There may be a tendency here to undue refinement, but it cannot be denied that the more the histology of kidney disease is studied, the stronger will be the conviction that there do exist varying types of disease, essentially distinct, included under the somewhat lax and unscientific heads of Bright's disease—acute and chronic. We may trace the same grasp of details and power of analysis which are so characteristic of Professor Ziegler in his chapter on diseases of the lungs, and especially in that on tubercular disease; but it would not be possible to do full justice to his treatment of this important subject without free quotation and extended notice. Suffice it to say that the pages devoted to this subject will well repay careful study; whilst one cannot fail to note the importance assigned to aspiration of tuberculous matter in the extension of the disease, which also spreads by peripheral extension, by tuberculous lymphangitis, and by intravenous tubercle. The section on the nervous system opens with a chapter upon the structure of the

Digitized by Google

brain—more detailed than usual in a pathological text-book, yet of considerable importance for the interpretation of morbid lesions. The chapters on softening, and on sclerosis—which is regarded in the main as degenerative and atrophic rather than inflammatory,—and the further chapters on inflammatory disorders of the brain and cord and their membranes, are fully abreast of present knowledge; whilst the final chapter on the disorders of the peripheral nerves will be read with interest, as embodying the views of the pathologist upon degenerative and neuritic lesions, which are daily receiving fresh attention at the hands of clinical observers.

We have said that this work is highly appreciated. In Germany it enjoys a remarkable popularity, having already gone through four editions. We venture to think it will be equally popular in this country, for it is a work which appeals both to student and to teacher. The former will gain from it a clear insight into morbid processes, and will be enabled to compare the results of his observation in the post-mortem room with the interpretations of the scientific pathologist. He will be greatly aided in this by the large number of highly executed engravings which illustrate the descriptions of histological appearances. The latter cannot fail to be quickened in his teaching and assisted in his exposition by a work which traverses the whole field of pathology in a systematic and orderly way. The book has a twofold merit: the text is not overladen with detail, and is therefore valuable as a text-book; and its ample bibliographical records render it equally valuable as a work of reference. Dr. MacAlister deserves the best thanks of pathologists for his labour and skill as translator and editor; and the publishers also may be congratulated upon the excellent manner in which they have fulfilled their part in its production.

Practical Medicine and Medical Diagnosis. By BYROM BRAMWELL, M.D. Edinburgh: Young J. Pentland. 1887.

THIS is evidently the first instalment of what promises to be a work of great merit; for it deals only with matters more or less introductory to the wide subject of medical diagnosis—such matters, namely, as methods of diagnosis, case-taking and case-recording, and medical thermometry. The work is based on the instruction which the author gives to his class at the Extra-mural School in Edinburgh; and, judging by its quality, we may fairly congratulate the students upon having so efficient and able a teacher. Dr. Bramwell speaks with all the authority of one who has himself fully mastered his subject, and we have nothing but commendation for the clearness and method with which he endows his subject. The chapter on case-taking is a model of what real instruction should be—guiding the student to orderly methods in his search after clinical facts, and the adoption of a strict line of inquiry into the antecedents of the case he is investigating. In the chapter on thermometry there are introduced short disquisitions upon the theory of fever and upon differential diagnosis, whilst the various types of pyrexia are fully illustrated. In the appendix will be found some pertinent remarks upon out-patient practice; and we are inclined to agree with Dr. Bramwell that senior students rather than junior should be occupied in this department. The rudiments of diagnosis are better learnt at the bedside than in the crowded out-patient room. We shall anticipate with pleasure the publication of further chapters of this undertaking, for which its author is so thoroughly well qualified.

La Goutte, sa Nature et son Traitement. Par Dr. W. EBSTEIN. Traduction du Dr. E. CHAMBARD. Revisée et augmentée par l'Auteur. Paris: J. Rothschild. 1887.

THIS is a veritable *édition de luxe* of Prof. Ebstein's well-known work; and it is prefaced by a brief and complimentary introduction to this French edition by Prof. Charcot, who trusts that in the next edition the author will take cognisance of Professor Bouchard's lectures on retarded nutrition. Ebstein's views are now fairly widely known, the main thesis being to support the doctrine of Garrod as to gout being due to a retention of uric acid in the system. This is demonstrated from the pathological side by the proofs that no gouty deposits occur in any tissue or organ except in places where the tissue has undergone necrosis, the notion being that such a retrogressive metamorphosis is induced by the action of uric acid upon the tissue. Experimental proof of this action is afforded in the results of ligature of the ureters in fowls, when, owing to retention of the excretion, highly charged as it is with uric acid, necrotic foci and deposit of crystalline urates are produced, similar changes being brought about in the kidneys when the secreting structure is damaged by the previous injection of chlorate of potash subcutaneously. Similarly, direct injection of uric acid or its compounds into the blood will produce like effects. The clinical part of the work deals with primary articular gout and primary renal gout—a distinction not perhaps generally appreciated, but fairly justified by facts. The therapeutical section is not marked by any considerable novelties, save perhaps in the rather liberal prescription of albuminoid and fatty foods, as compared with restriction in carbohydrates. An English translation (by Dr. Scott) of this work was published two years ago, but it did not, as this French edition does, contain the chromo-lithographs which represent the histology of gouty lesions in tendon, cartilage, kidney, &c., in a striking (perhaps a too vivid) manner.

Contributions to Practical Medicine. By JAMES SAWYER, Knt. Birmingham: Cornish Brothers. 1886.

SIR JAMES SAWYER has collected some of his scattered writings and subjected them to revision before reproducing them in the elegant form presented by this volume. The lectures and essays embrace such subjects as Insomnia, Intestinal Obstruction, Floating Kidney, and Phthisical Laryngitis; and they are treated in a thoroughly practical manner. That on the causes and cure of insomnia and that on constipation and intestinal obstruction strike us as being the most suggestive, and best illustrating the practical bent of the author. The essay on "floating kidney" is interesting, but in being revised it should have made mention of the great benefit derived by the surgical method of "nephrorrhaphy." The author has the faculty of expressing his thoughts clearly, and he is careful to avoid the too common mistake of writers—viz., the statement of facts outside their own experience. The book bears the impress of personal conviction, and is therefore likely to be appreciated by its readers.

ARMY MEDICAL SCHOOL.

THE summer session of the Army Medical School was opened at Netley on Friday, April 1st. Twenty-five surgeons on probation of the British Medical Service and twenty-eight of the Indian Medical Service were in attendance. The introductory address was delivered by Professor Aitken, F.R.S., in presence of the military and medical staffs of the Royal Victoria Hospital and School and a few visitors. The lecturer took for the subject of his discourse, "Recent Pathological Researches on the Production of Disease by Infective Processes generated within the Body." In the course of his preliminary remarks he referred to the illness of his colleague Professor de Chaumont, and to the probability of his being unable to take part in the teaching of hygiene during the present session of the school, and mentioned that it had been arranged for his duties to be taken by Deputy Surgeon-General Dr. Marston, head of the sanitary branch at the War Office, who possessed very extensive experience in the subject of hygiene both at home and abroad, and who would be aided by Surgeon-Major O'Reilly, as well as by the Assistant Professor of Hygiene, Dr. Davies.

THE LANCET.

LONDON: SATURDAY, APRIL 9, 1887.

THE Medical Council is summoned to meet on Tuesday, the 10th day of May—of course in consequence of the chaos into which the examining system is thrown, especially in England, by the determination of the Royal Colleges to exclude the Apothecaries' Society from their Conjoint Scheme. The refusal of the Colleges places the Council in a very delicate position. Those who were so enamoured of the Act of 1886 may now see how much reason we had for dissatisfaction with it. The wish of the Medical Council is thus set at nought by the Royal Colleges, and we are threatened with the perpetuation of a race of practitioners not good enough, according to the standards of the Colleges—though they have no mandate to exact higher tests than those of efficiency in medicine, surgery, and midwifery. The Royal Colleges are in a state of prosperity and hilarity just now. Their funds abound, and their diplomas are in demand; but it can only be regretted that they have not used their great wealth and prosperity to cement the profession, to abolish its divisions, and to assist in the creation for England of one grand portal for her general practitioners. They have chosen to do otherwise, and to refuse the request of a majority of the Medical Council preferred by its respected President. It is not for us to anticipate the consequences of this step. But it places the Apothecaries' Society in a position in which we are sorry to see it placed. It would have been more magnanimous in the Royal Colleges to have sought the disestablishment of the Society by direct legislation than by refusing to recognise its claim to co-operate with the other authorities under the legislation of 1886. It would be idle to ignore the painful position in which this decision of the Colleges places the Medical Council. Only one thing is certain, that the Council can never acquiesce in the creation of an inferior Examining Board, to authorise something less than efficient practitioners for people who are too poor to recompense, or too unimportant to require, an efficient medical man. Such seems as we showed last week, to be the dream of some Members of the Royal Colleges who are so lightly treating a request of the Medical Council. The Medical Council has no authority to recognise a lower standard at Blackfriars than on the Thames Embankment, and the creation of an inferior class of practitioners would be as disastrous to the profession as it would be unfaithful to the Medical Act. If the Medical Council determine to grant additional examiners to the Hall, it will not be likely to take any low estimate of the additions that will be necessary. For twenty years medical reformers have hoped for legislation that would have equalised what ought to be equivalent examinations, so that medical men who have obtained their qualifications from one body could hold their heads up before those who have received their qualifications from a similar body in another division of the kingdom. But only last week Mr. BERKELEY HILL commented on the convenience of Edinburgh, Glasgow, and Dublin as places of refuge for those who have been repeatedly rejected in London. We leave the representatives of Edinburgh, Glasgow, and Dublin to make their own acknowledgment of this compliment from one of the Council of the College of Surgeons of England. Our present purpose is rather to direct the attention of the Medical Council to Mr. HILL'S view of its duty at the coming meeting—viz., to give sanction and status to a body that will pass men whom the Royal Colleges of England will not think worthy of being passed. This raises a view of the duty of the Council which cannot be too seriously considered before it meets. It will be curious if the Medical Council should become, as it were, partners in a third-rate Examining Body meant for the accommodation of those plucked by the Colleges chiefly charged with testing the efficiency in candidates.

The retirement of Sir HENRY ACLAND at the approaching meeting will throw upon the Council one of the most difficult and important duties which it has to perform. Hitherto it has been free to take its President from outside the Council. Now, under the Act of 1886, it must choose one of its own members. There has never been a time when it was of so much moment as it is now that the President should be a man of strength, of impartiality, and of public spirit. We have given one specimen of the questions about to engage the attention of the Council. There are half a dozen more; and if the Council considers its own future reputation it will select a President with such qualifications as we have named.

THANKS to the many labourers in the field of neurology, we are by no means in total darkness concerning the nature of hypnotism, catalepsy, trance, and allied conditions. Doubtless we see through a glass darkly, but this may be said of all knowledge, including medicine. We shall first give an exposition of the facts met with in the states under consideration, and then bring this knowledge to a focus, and endeavour as far as possible to see what anatomical and physiological interpretations may be put upon the facts. It would take up far more space than we have at our present disposal to discuss the strictly psychological and other mental aspects of these diseases, but we believe that at the present juncture a physiological explanation or attempt at an explanation may prove acceptable in the face of the case of M. CHAUFFAT, now attracting so much public attention.

In catalepsy, hypnotism, and the like states, the conspicuous feature is the loss of the ordinary consciousness of the individual, the subject of the abnormal state. This loss varies in degree. It may be profound and deep, so as not to be recovered by any artificial means, or it may be recoverable by external stimulation of greater or less intensity. Again, it may vary in itself, probably as the result of internal conditions of the cerebral cortex, and this variation may be so great that, on the one hand, consciousness is almost normal, or, on the other, fully in abeyance. It is most necessary to recognise this irregularity and variability in order fully to understand, so far as is possible, all the facts that have hitherto been observed. There are, besides the loss of consciousness, other phenomena of which mention must be made. And the same variableness may be met with in these. An individual in

Digitized by Google

the hypnotic state may perform certain actions, often of a complicated nature, under the influence of what our Paris *confrères* call "suggestion." This fact implies the persistence of function of certain tracts of brain tissue almost certainly situated above the level of the lowest sensori-motor areas, spino-bulbar centres, and probably in the cortex of the cerebrum and cerebellum. In catalepsy, as a rule, rigidity of the voluntary muscles also exists, and likewise a condition known as wax-like plasticity—flexibilitas cerea—a state which is detected after overcoming the primary muscular rigidity, and which allows of the limbs or other parts of the body being placed in the most awkward, constrained, and inconvenient postures. Indeed, the tissues appear to be as plastic as wax of a certain temperature, and can be moulded almost to the same extent. Once moulded, the tissues take on a rigidity that casts the muscles as though they had suddenly solidified, and from pliable wax had become solid bronze. But this is not all. Certain kinds of stimulation—as, for example, gentle but rapid stroking of the skin, or pressure on some nerves—have the property of relaxing the rigidity and of causing the limb or part to return to its customary condition. Of the accuracy of the facts which we have just described there can now be no kind of doubt. The phenomena may be ascertained without the slightest difficulty. Take, for example, the fixation of the leg of such a patient as CHAUFFAT. Let anyone in full health, strength, and consciousness try conclusions with this patient. He will find that attempts at maintaining his own lower extremity in the posture he may already have placed CHAUFFAT's will not be long successful. Most recumbent individuals could not maintain one leg raised at an angle of 60° for more than fifty or sixty seconds, without considerable pain and tremulousness developing, and leading to a strong desire to desist from the continuance of a task involving so much distress. With CHAUFFAT, or another cataleptic, several minutes would elapse ere tremor developed, and the leg would not fall until complete exhaustion had set in—an exhaustion that takes a much longer time to appear than in a conscious healthy subject. It is hardly possible for anyone to simulate the condition of flexibilitas cerea, and it does not seem within the bounds of reason to suppose that a conscious individual would permit the various painful excitations of his senses without evincing some signs of his having experienced them.

The explanation, anatomical and physiological, that we have to offer may be fairly stated in the following manner. Consciousness is only possible physiologically when the bulk of the cortical perceptive centres are in a state of normal functional activity. Loss of consciousness varying in depth is concurrent with loss of function of the cortical perceptive centres, also varying in degree. We know as well as it is possible to know that removal or damage of the whole of the cerebral cortex behind the "motor region" would destroy perception of all sensory impressions. We are also perfectly certain that a still more limited lesion of the centripetal paths could produce a similar effect. An individual in whom the "sensory crossway" or posterior third of the posterior limb of the internal capsule on each side had been completely severed would be totally anæsthetic to impressions on his tactile, auditory, visual, olfactory, gustatory, and probably visceral organs. If we imagine that in catalepsy there is a total loss of the functions of the cortical perceptive centres—a loss that may be caused by essential molecular changes, or due to blood poisoning or coarser disease—for it must be remembered that meningitis, tumours, softening, and malaria may be the efficient causes of catalepsy,—an explanation, imperfect and incomplete we grant, would be forthcoming of the symptoms and signs met with in catalepsy and hypnotism. It is highly improbable that an individual in possession of the proper use of the "motor" and prefrontal regions of his brain would be in a state of ordinary consciousness. In these regions are locked up innumerable motor mechanisms, and these may be unlocked and set agoing through the centripetal channels not concerned in the causation of consciousness. Indeed, it is a fact that all the movements which a cataleptic individual can be made to perform come within the category of automatic movements. It is clear that in the absence of consciousness new movements cannot be acquired, and we may take it for granted that mechanisms exist, preformed in the brain, for all the actions ordinarily performed by us. As an illustration, we need but mention the circumstance that most individuals go through such processes as undressing in a purely automatic fashion, the mind being occupied all the while by a train of thought. The placing of CHAUFFAT's hand in the fighting posture leads to the development of a menacing expression of the countenance. Consciousness need not be involved in such an association, for it is certain that mechanisms of a sensori-motor kind exist near together in the motor region of the brain—a region which there are good grounds for believing may be the seat of "muscular sense" as well as of certainly efferent motor impulses. Plasticity and rigidity of muscle can hardly be explained on the assumption that the bulbo-spinal centres are alone in action. It would obviously not explain the former phenomenon, and certainly not the rigidity; for this implies over-action, of which there is no other evidence than the mere rigidity, for the reflexes as a rule are not increased, and may even be diminished, in catalepsy.

IN whatever shape the proposals of those anxious for the reform of the University of London may be adopted, the existing constitution of the University is doomed. In Sir E. FRY's original scheme, in that of Sir P. MAGNUS, and in the one now before the Senate, associated Colleges and their representatives are introduced between the Senate and the members of Convocation, and duties of more or less importance are to be delegated to them. The Senate and the graduates in Convocation will be supplemented by Faculties and Boards of Studies, either as such, as in the new scheme, or as a Council of Education, as suggested by Sir P. MAGNUS, and on these the representatives of the Colleges will form the chief or sole element. It is by this infusion of teachers that the business of a local university is mainly to be carried on; but we question much whether the graduates in Convocation will not successfully attempt to weaken these clauses and substitute for them those in Sir P. MAGNUS's scheme. If such a course be adopted, the teaching element will be small in proportion, and so liable to be outvoted in the Boards of Studies and the

Digitized by Google

Council of Education by representatives of Convocation, who may have no knowledge of the requirements of a suitable curriculum, so that the value of the other proposals will be reduced to a minimum. But even if the provisions of the new scheme be passed, they are too cumbrous and too ill-defined to give any reasonable hope of their being made capable of forming a basis for a real Teaching University, which is the great want in London. Bodies of insufficient weight and standing must be admitted if these clauses stand, and the larger educational Colleges will practically have no increased representation, influence, or power. This seems to us a fatal objection to the scheme. It is better to wait for a real Teaching University in London than to adopt a feeble substitute, which will weaken the absolute rule of the present Senate and impair the efficiency of the Examining Board for the empire, and not satisfy the aspirations of the teachers in the London Colleges which can fairly claim to be of university rank and standing. These defects will be clearly shown in an analysis of the proposed changes.

The University is to consist of (1) Senate, (2) Convocation, (3) Associated Colleges, (4) Faculties, (5) Boards of Studies, with the Queen as visitor, instead of merely Senate and Convocation as at present. The thirty-seven Fellows composing the Senate are to be divided into sixteen Crown nominees, the chairman of Convocation, twelve representatives of Convocation voting as graduates in Arts, Laws, Science, and Medicine separately; and eight direct representatives of the Faculties, also voting separately. The representatives of University and King's Colleges, the Colleges of Physicians and Surgeons, and of the Legal Councils, which were expressly named in the former schemes, have disappeared altogether, and their places are practically given to the representatives of the Faculties, so that the exceptional position of University and King's Colleges, and the advantages of association with the medical and legal corporations on which formerly so much stress was laid, are now put aside; but by a majority of one the Senate has determined that this question shall be reconsidered by the Special Committee. Life Senatorship is to be abolished in favour of a tenure of eight years; but Convocation has already favoured the still shorter period of four years, and this seems to us preferable, especially as retiring members are eligible for re-election. Except for an increase from nine to twelve representatives on the Senate, the powers of Convocation will remain unchanged, whereas, in Sir P. MAGNUS'S scheme, which Convocation adopted on June 29th, 1886, members of Convocation, as well as the Colleges and the examiners, were to form the Council of Education or intermediate body between the Senate and the graduates. This difference is a vital one, and we fear it will endanger the passing of the scheme through Convocation, whilst, if the alternative be adopted, the whole scheme will in the eyes of the teachers be worthless. The Faculties are now to be constituted solely by the representatives of associated Colleges, divided under Arts, Laws, Science, and Medicine, and each Faculty will elect members, who, with an examiner in each subject in the Faculty, will constitute the Board of Studies in each Faculty. These Boards of Studies will elect a chairman every year; consider and report to the Senate upon any matter referred to it by the Senate; express opinions on any matter connected with degrees, examinations, and teaching; and deliberate, if so requested, with the Senate, or report to the respective Faculties. They will thus form either distinct or conjoint permanent consultative bodies, whilst the Senate remains the sole executive. The associated Colleges are to be selected from Colleges and teaching institutions in any part of the United Kingdom, and may be named in a schedule prior to any application for a Charter, or be afterwards admitted by a Committee of Selection. This will be considered a weak alternative by those interested in promoting a Teaching University in London, and cannot but be opposed by that Association. The Medical Schools and Colleges from which the University receives certificates for degrees in Medicine will retain their right of giving such certificates, whether they be or be not associated Colleges. The present method of granting degrees is to be maintained, except that the Senate will ask for power to grant honorary degrees, which Convocation has always steadily declined to sanction. The last clause is so peculiar that we reproduce it *verbatim*: "Power to hold real property, and to accept grants, gifts, devises, and legacies for the purposes of the University, including the establishment of professorships and scholarships, and the furtherance of regular and liberal education and of original research. Provided that no professorship or lectureship be established in the University of a kind likely to compete with any teaching given in University College, London, or to injuriously affect the reasonable prospects of that College." Negotiations with that College will be held before applying for a Charter. The opposition of University College is to be bought off by this clause, and every other College and Medical School must take care of itself. A more palpable bribe to the section of the professors in University College which opposes the movement for a Teaching University, or a more unfair proposal, was never introduced into a University scheme than this proviso. Other institutions are concerned in the higher medical and general education as well as University College. As some questions are referred back to the Special Committee, which is requested to confer with the Committee of Convocation, and then report to the Senate, it is obvious that the scheme will not be sufficiently complete to lay before Convocation at the May meeting, and that a special meeting will have to be summoned for its consideration at a later date.

PROFESSOR MAX MÜLLER has inaugurated a good work, which may be described as the repair of philosophical breakages. There can be no question that philosophy and science are suffering from that merciless reduction of their subject-matter to very small pieces which has resulted from abuse of the analytical method, both in inquiry and in criticism. The aim of every student of art and nature has been to discover differences between things, and to formulate what have been termed *specific* characteristics with a view to classification. It has been so in the natural sciences, and it has been so in what may be termed the unnatural sciences, or those which deal with abnormalities, including pathologies. The gain would be enormous if this plague of disintegration could be stayed. Professor MAX MÜLLER thinks DARWIN would have added greatly to the already high value of his services to philosophy and science if he had abandoned the term *species* when he placed the facts

Digitized by Google

of differentiation in a new light by his discovery. Accepting, as we must, the doctrine that words are not merely the instruments, but in a sense the integers of thought, it is manifest that any misuse of terms must be of more serious moment than any mere clumsiness in the naming of facts. MAX MÜLLER would improve our intellectual work and clear our brains by purifying our language, and with a view to the simplification of the task he would have us cut adrift as much as possible of the lumber that encumbers and strains both philosophy and science. This is the lesson we read in his lecture on Thought, and it is one that may well be learned by all who have the real and far-reaching interests of truth and knowledge at heart. To think simply and well is the first condition of good and useful labour in the province of mind; and simple, clear, and effective thinking is not possible unless "thinks," or *things*, are understood in their simplicity. The practical difficulty of simplification lies in the fact that everything is many-sided, and that, in order to obtain a sufficient notion of an object or a subject, we must, so to say, walk round it and observe each of its faces, and in doing this we cannot possibly avoid making such abstractions as are essential to the recognition of differences. There is food for earnest reflection in Professor MAX MÜLLER's discourse on this most interesting subject, and we can only regret that it does not form part of his programme to point out precisely how the fragments of knowledge grouped under the head of the medical sciences might be pieced together in such fashion as to make the views of those who need to be especially single-eyed and clear-sighted less obscure and more complete.

Annotations.

"Ne quid nimis."

DEGREES FOR LONDON MEDICAL STUDENTS.

THE decision arrived at by the Committee of Delegates of the Royal Colleges of Physicians and Surgeons to recommend their respective Colleges not to confer at present with University and King's Colleges, but to proceed conjointly and independently of other bodies, in their endeavour to obtain the right to confer degrees in Medicine and Surgery, will be received with much regret by all who are anxious to secure an academic degree for medical students in London, and will in no way diminish the opposition to a mere professional title, but tend to increase it. The provincial schools will insist on their claim to equal rights and privileges with the London medical schools, in any action taken by the two Royal Colleges, of which they claim to be constituent factors, and they will be strengthened by the professors and councils of University and King's Colleges, who will protest against a degree being conferred, in one Faculty only, by two professional corporations without university rank or academic status. The entire weight of the University interest in London and the country will now be thrown against the scheme, whereas by conjunction with University and King's Colleges the antagonism of the University of London would have been the only opposition to be apprehended on the academic side, and we have no doubt on which side the argument for "least resistance" really lies. With the University of London applying for a new charter, which will be opposed by many of its own graduates in Convocation and by those who are promoting the movement in favour of a Teaching University in London; with University and King's Colleges also applying for a charter to grant non-medical degrees, which will be opposed by the existing University, which dares not let its largest colleges secede without a struggle; with the Royal Colleges, again, endeavouring to obtain a charter to grant medical degrees—a movement that will be opposed by the provincial schools if a residential qualification be inserted and only half-heartedly supported by London teachers if this be omitted; by University and King's Colleges, who know that now or never they must become real constituents of a University; by all interested in founding a Teaching University in London, who will not willingly see the chief Faculty of such a University slip from the combination; by the Irish and Scotch corporations, which will seek similar powers out of jealousy and self-interest; and by the Apothecaries' Society, which has been contemptuously thrust aside,—the outlook is not a hopeful one. We are quite sure that it would have been more to the advantage of students if the question had been considered on a wider basis, and that less opposition to the degree would thereby have been aroused. Indeed, we still hope that the Crown will insist on the different bodies waiving their personal prejudices and jealousies, and compel them to unite to form a real University, such as exists in every metropolis and educational centre in the world except London.

RECENT CHANGES IN EXAMINATION REGULATIONS.

Two regulations of some importance to students were recently passed by the Colleges of Physicians and Surgeons upon the recommendation of the Committee of Management. The one refers to the period at which a candidate may again present himself after rejection at the final examination. Hitherto this period has been fixed at six months—rather a long time in the case of those who nearly attain the requisite standard, and entailing some hardship at the close of their curriculum. We think that the Committee have done wisely to allow such candidates as obtain fourteen out of the fifteen marks required to pass such examination to be admitted to re-examination after a period of three instead of six months' study. The other change adopted is in the regulations for the primary and elementary examination in anatomy and physiology. It allows a candidate to be admitted to this examination on the completion of his first six months' attendance at a recognised medical school (exclusive of the months of April, August, and September), instead of the stipulation that he should not be allowed to compete until the close of his first winter session. This change ought to be productive of a larger May entry in the schools, and a large number of candidates at the January examination, which will greatly relieve the plethora now experienced in April. With reference to this question, it may be useful to point out certain other directions in which these examinations may be improved. The principle recognised in the foregoing regulation of the first examination might well be applied to the second examination also; and in that case there would be no need to hold more than three such examinations yearly. The October examinations in anatomy and physiology are of little advantage, since the schools are closed during the greater part of the interval between that examination and the preceding. It is only for the final examination that the opportunities for study—i.e., clinical work—are available during this time. Again, the option allowed to candidates of entering for one subject only should not obtain for the second examination, anatomy and physiology being so closely connected with one another. A more liberal system of marking might also with advantage be introduced, for a maximum of fifteen marks for a whole examination is an absurdly small number, and must be diffi-

Digitized by Google

cult for the examiners to work with satisfactorily. Lastly, a candidate who has been rejected in all the subjects of the first examination is required to pay a higher fee than that originally charged, for a rejection in each of the four subjects entails an additional fee of £3 3s., so that on his second appearance he pays £12 12s. instead of £10 10s.! This is clearly anomalous, and has probably been overlooked by the Committee of Management, who might profitably take the whole subject of fees into consideration.

THE ELECTION OF PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.

WE are glad to chronicle the fact that, at the meeting of the College of Physicians on the 4th inst., Sir William Jenner was for the seventh time elected to fill the office of President. The somewhat antiquated mode of election, without previous nomination, required (as it often has done) a second ballot, for unless on the first voting the Fellow whose name stands first has obtained the suffrages of two-thirds of those present at the meeting, the Fellows are called upon again to decide between him and the Fellow whose name stands next on the list of the first ballot. It is clear, therefore, that the first ballot does not indicate the full wishes of the College, many names often being returned with the view of showing who are eligible for the high office. It may be interesting to note that Sir William received 73 votes out of 120, the Fellows amongst whom the remaining 47 votes were distributed being Sir William Gull, Dr. Quain, Sir A. Clark, Dr. Wilks, Dr. Johnson, Sir H. Pitman, Dr. Andrew, and Dr. Ogle. Sir W. Gull's name on this occasion stood second, and the second ballot resulted in the return of Sir W. Jenner by an overwhelming majority—99 to 13. Sir William accepted this result as the practically unanimous wish of the College that he should continue as President for a seventh term, and he suitably expressed his sense of the high honour thus conferred.

PHYSIOLOGICAL ACTION OF NITROUS OXIDE GAS.

DR. DUDLEY BUXTON has communicated two valuable papers upon the above subject to the Odontological Society, based upon numerous clinical observations and experiments. The effects of nitrous oxide inhalation upon the mammalian organism are, he says, broadly speaking—(1) a condition of anæsthesia; (2) an emotional state, provoking a sensation of exhilaration—in fact, it plays the *rôle* of a stimulant; (3) it gives rise to modifications of the respiratory and (4) circulatory systems; and (5) provokes marked muscular movements, which may be classed as (*a*) rigidity and (*b*) jactitations. The anæsthesia produced by nitrous oxide is not dependent upon analgesia or loss of sensation of painful impressions of the sensory end-organs, such as that produced by cocaine &c., or upon failure of the conducting sensory nerves, for sensation is retained until the perceptive powers themselves cease to receive; moreover, there is immediately anterior to the loss of consciousness a hyperæsthetic stage, therefore it may be concluded that the nerve centres are acted upon. The ways by which nitrous oxide may enter the system, and is enabled to produce its special effects are—either that it gives rise to other bodies by changes in its chemical form, or by acting as an irrespirable gas and causing asphyxia, or by exercising a specific action, just as strychnine does. Dr. Frankland came to the conclusion that nitrous oxide was not decomposed during its sojourn in the body, basing his opinion upon analyses made of the air expired by rabbits when confined in an atmosphere of mixed air and nitrous oxide. In the first stage of asphyxia, that of dyspnœa, there is an increase in the respiratory movements, both inspiratory and expiratory; in the second, a dominance of the expiratory efforts, culminating in general convulsions; in the last, exhaustion, with long-drawn inspirations, gradually dying out. The blood-pressure during the first and second stages rapidly rises. Dr. Dudley Buxton has never observed an increase in the expiratory movements when HO_2 has been administered, which are merely increased in number and depth, or expiratory convulsions, notwithstanding the gas has been pushed to its utmost limit, and from a large number of sphygmographic tracings the tension in the arteries has been lower than normal. In experiments upon dogs, Dr. Buxton found that where a trephine-hole was made through the skull, during the inhalation of the gas the brain pulsations became more forcible and somewhat hurried; then the brain substance was seen to swell up, until at last it actually protruded through the aperture; whereas in a similar experiment, with the trachea occluded, the brain receded, sinking away from the opening. Other experiments showed that the heart's action was but little interfered with by nitrous oxide, even where the inhalations were pushed until respiration was interrupted; during asphyxia, on the other hand, a rapid and continuous increase in blood-pressure invariably occurred. The dose of nitrous oxide required to produce insensibility varies very considerably in different persons—a fact which supports the view that nitrous oxide exerts a specific action on the nerve centres. Dr. Buxton also discusses many other interesting points in the action of the gas, such as the occurrence of hallucinations.

THE CASE OF TRANCE.

NORMAL consciousness has not yet returned to M. Chauffat, who is now in the thirteenth day of his "sleep." But there are signs indicating the possible near approach of restoration to the natural state of life. The loss of consciousness is less profound. It is possible to awake Chauffat with but little external stimulation. Moreover, during the past three days evidence of a wider awakening of intellect has been shown; acts are performed indicating the revival of considerable powers of memory. The anatomical substratum of mind can be aroused to such a state of activity that apparently correct answers relating to questions involving a ready remembrance of past scenes and acts may be obtained from the patient. These replies cannot be communicated by word of mouth, but Chauffat makes himself understood by the aid of fair penmanship. To the lay mind, doubtless such facts appear extraordinary, but medical men are familiar with cases of brain disease in which similar phenomena obtain. As happened after Chauffat's previous attacks of hysterical catalepsy, paralysis of the left leg and dumbness persist some time after the recovery of power over the other movements of the body. It is difficult to explain in Chauffat's case why the cerebral centres controlling the speech movements—ordinarily subserved by the *left* side of the brain in right-handed individuals—and those presumably in the right side of the brain presiding over the movements of the left leg should remain so much longer in the "sleeping" state than the large remainder of the cerebral cortex. The ultimate recovery of these centres, however, proves that they are not the seat of gross changes. Employing an analogy from electricity, we may imagine that the speech and left leg centres take a longer time to recharge with the vis nervosa. It may be remembered that Chauffat has uttered a few words, such as "thief," "scoundrel," and a number which is believed to be that of the cab in which he was last driven. Such ejaculations also show that the speech centres can be thrown into action, but probably only as the result of powerful excitation. This is in accord with all previous observations. It may be asked why the above-mentioned words, and not others, were spoken. The reply to this question is that it is very pro-

Digitized by Google

bable that the words were some of the last used or about to be used by Chauffat before he became unconscious. Highly probable is it that the molecular changes, the accompaniments of these words, in the speech centres leave more than usually permanent traces, the physical bases of memory, which render the words more liable to be uttered, under the influence of incitations, than words which have left less indelible markings. The other functions of the patient have undergone a satisfactory improvement, but their condition presents little that is of special interest. We may refer for further comments on the trance condition to an article on page 736.

THE CROONIAN TRUST.

AFTER some delay and much discussion, the Royal College of Physicians have agreed to a scheme whereby the large funds that now accrue from the Croonian Trust may be utilised. It may be remembered that last year it was decided that there should be one or more lecturers appointed "to deliver lectures on one or more subjects in Anatomy, Physiology, and Pathology, with a view to the prevention, control, and cure of diseases," and that the funds should be administered in payment of such lecturer or lecturers, and in promoting scientific investigations on the subjects of the lectures. The regulations adopted at the last meeting of the College—which will be found on another page—are in accordance with these resolutions. It will be seen that provision is made for the reappointment of the lecturer, whose duty it will be to deliver a course of not less than four lectures annually. In this way the lecturer will be free to take up subjects which may entail prolonged investigation. At the same time, it might have been well to have placed some limit upon his term of office, the only objection to that being that he might feel bound in every case to hold it for the full number of years assigned. The devotion of the surplus of the fund to defray expenses of original investigation by a past or present Croonian lecturer strikes us as somewhat limiting the benefits to be derived from the fund; and we should prefer to have seen the proposal to nominate, from time to time, a junior Fellow to a Croonian Fellowship. But the committee, who doubtless considered this point, may have felt their hands tied by the original terms of the trust. It now remains for the choice of the President and Censors to be made with circumspection; and we may hope that the cause of scientific medicine will be promoted in the selection of lecturers who will be enabled to devote their time to original investigations. Lastly, it may be noted that the time fixed for the delivery of the lectures is in the month of June, instead of in March as at present, and that the first course will be given in 1888. It must therefore soon devolve upon the President and Censors to make their selection.

ALLEGED ILL EFFECTS OF VACCINATION.

AN inquest was held by Dr. Danford Thomas on the 29th ult. touching the death of Ellen Jane Herring, aged four months. The deceased child was vaccinated by the public vaccinator a month prior to its decease. A few days before death another medical man was consulted as the child grew ill. Coma supervened and proved fatal. A certificate was given that death was due primarily to meningitis, and secondarily to "the effects of vaccination." The vaccinia had progressed in a normal manner in every particular. There was very little constitutional disturbance, and unusually little inflammation about the vaccination points. Several other children were vaccinated from the arm of deceased. There were no signs or symptoms of blood poisoning. The manner in which the death certificate was written was most unfortunate, for at the inquest the doctor who signed it deposed that he intended to convey no more than that vaccinia, being a specific fever, had somewhat lowered the vital powers of the child, and so to a certain extent had acted as an accelerating cause of death. So far this was true, but both the popular and professional interpretation of the certificate would be something far graver. In short, the certificate was calculated to credit vaccination with the death, and discredit a valuable life-saving procedure. Very properly a post-mortem examination was ordered to be made. At the necropsy it was found that there was typical tubercular meningitis with hæmorrhage beneath the arachnoid. The inflammation was purely basal. Both lungs were thickly studded with quite recent miliary granulations. The mesenteric glands were tubercular, some containing caseous matter, and others suppurating. There were no metastatic infarcts or abscesses; in fact, there was complete absence of anything that could be assigned to pyæmic infection. The vaccination scars were normal, and there was no infiltration of inflammatory matter around them or in the associated lymphatic glands. Mr. Pepper stated that, in his opinion, the vaccination had been satisfactorily performed and that the vaccinia had run a natural course; and, further, that the vaccination had little or no effect on the development and progress of the tuberculosis, which had commenced previously to it, and which would inevitably have proved fatal within a short period had vaccination not been performed. The jury unanimously accepted these opinions, and recorded the same in their verdict.

THE CARMARTHEN INQUEST CASE.

ON March 25th last an inquest was held at Carmarthen before Mr. John Hughes, F.R.C.S., coroner, concerning the death of George James, aged forty-seven, head constable. From the evidence reported we gather that deceased had suffered for some time from nervousness and want of sleep, but that otherwise he was not known to be in ill-health. Soporifics had been administered by Mr. J. E. Edwards, M.R.C.S., and on the day of his death deceased applied for more medicine. Mr. Edwards made up a draught containing half a drachm of chloral hydrate and half a drachm of bromide of potassium, and gave both written and oral instructions that half the contents of the bottle were to be taken at once and the other moiety three hours later if required. Deceased wilfully disobeyed the doctor's orders and took the whole quantity in one dose, and almost immediately died. If the medicine was dispensed as described we cannot doubt that the death was due to other causes, and even if the dose had been large enough to be probably a fatal one, we should not expect death to occur so suddenly as it did. The medical man who made the post-mortem examination deposed that "there were no symptoms of chloral poisoning, and no signs of disease in the internal organs, and he could offer no opinion as to what was the cause of death." The jury returned the verdict, "Death by the visitation of God." On theological grounds such verdict might be found in every case of death; but from a medical and scientific standpoint it is merely a record of ignorance of the facts underlying the event under consideration. It must not be concluded that because no chemical tests for chloral give affirmative evidence of its presence in the body after death, therefore it may not have been taken even in a lethal dose, for experience teaches the contrary. In our opinion, Mr. Edwards must be acquitted of all blame in the unfortunate matter of the death of Mr. James. He had a perfect right to prescribe chloral, if, in his judgment, he thought fit; and certainly he cannot be accused of carelessness in the matter of giving directions as to how the medicine was to be taken. We fully endorse the protest be made at the inquest, that he was not informed of the time and place of the post-mortem examination. To some

Digitized by Google

extent his professional conduct had been impugned by the friends of deceased, and, moreover, the coroner, in the exercise of his judicial function, cautioned Mr. Edwards as to the evidence he was about to tender, thus properly, but unfortunately, giving some colour to the loose accusation of blame that had been laid at his door. It is true there is no legal responsibility compelling the coroner, or the medical man commissioned to make the examination, to give notice to individuals concerned in the issue of the inquiry, but it is none the less desirable that such practice should always obtain. The coroner for Central Middlesex is very strict on this matter of procedure. With the order for making a post-mortem examination he encloses notices for any other medical men concerned, leaving the time of the examination to be filled in by the gentleman who is to officiate at the necropsy. We commend this discretionary action to all coroners, medical or otherwise. Mr. Edwards has our sympathy in the somewhat painful position in which he has been placed.

CONGENITAL OCCLUSION OF THE PHARYNX.

A SPANISH practitioner, Don M. D. Illera, gives in *El Siglo Médico* an account of a case in which a newly born child could not be taught to suck, and whose mouth on the introduction of the finger grasped it like a ring. On inspection the middle third and edges of the tongue were found to be connected to the superior alveoli by firm adhesions, which entirely prevented the organ from being depressed. In addition to these adhesions, two little tumours were seen on the palate near the arch of the fauces, which almost occluded the passage into the pharynx, thus rendering swallowing of liquids almost impossible. It was evident, therefore, that unless operative measures were resorted to the child must necessarily succumb very shortly from sheer inanition. The parents, however, though the state of the case was laid before them, refused to permit of an operation till the fourth or fifth day, when they decided to allow it. Don Illera seized the tumours with forceps and cut them off at the base, touching the bleeding surfaces immediately with the actual cautery. The adhesions were then divided, and after the application of a sponge with cold water for a few hours, repeated very frequently, the child was able to swallow some milk quite easily, and ultimately attained complete use of the tongue. Don Illera was induced to publish this case, as he once saw a similar case in which the practitioner in attendance had considered the risk of operation too great to be attempted.

MORAL DISCIPLINE OF LUNATICS.

GRANTED that very much of the wrong-doing of eccentric persons is the outcome of mental derangement, the question arises whether or not, in the interests of the individual as well as of society, it ought to be regarded as crime or insanity. We are of opinion that this question can never be answered as directly and simply as many respectable authorities desire that it should be. We incline to the belief that no hard-and-fast line can ever be drawn between crime and madness. There are undoubtedly, we think, cases in which, as Dr. Edgar Sheppard pointed out years ago, there is an admixture of wickedness and disease in which the proportion of the two constitutional elements may vary almost indefinitely. If that be so, then it is manifest that each individual case must be studied and treated on its particular merits. Accordingly, we are not disposed either to blame all judges and justices of the peace who sentence lunatics to terms of imprisonment, or to maintain the plea of insanity on behalf of all transgressors. Moral discipline of the sort which consists in the punishment of offences, whether these offences be wholly malevolent or partially insane, is by no means inadmissible in the treatment of mental disorder or disease. It is not for the advantage of the weak-minded that they should be allowed to think that the hypothesis of irresponsibility will cover any multitude of sins. Better far let these half-mad folk understand once for all that if they outrage public decency or assault their neighbours they will have to suffer for the offence. These are general remarks, and we do not wish to apply them specifically; but the principle of moral discipline is, we are convinced, a sound one, and neither the lunatic population nor the community as a whole will suffer by reason of its being enforced.

THE CORONER'S CENSURE ON A MEDICAL STUDENT.

LATE on Saturday night, the 26th ult., a man aged twenty-four, was taken to St. Thomas's Hospital by the police; he was said to have been "run over" by a tramcar about an hour previously. A medical man, who had seen him earlier, thought that he was suffering from internal injuries. The dresser who saw the man on his arrival at the hospital made a very careful examination, but failed to discover anything beyond a small scalp wound, two abrasions on the back, and another on one of the legs. The patient was quarrelsome, could not answer questions coherently, presented no signs of shock, and was in a condition of semi-intoxication. Without referring to the house-surgeon, the dresser, a Japanese gentleman, told the police to take him away. He was taken to the police-station and seen several times during the night, as he was very noisy and vomited frequently; he also went to the watercloset once. No complaint was made during the night, nor did he ask to see a doctor. In the morning he dressed himself, and then complained for the first time of pain in the epigastrium, but left the station by himself, having given bail. He was soon after found by a policeman, not far from the station, leaning against a wall and complaining of great pain in the abdomen. The man was taken to the Wandsworth Infirmary, where he died the same evening from peritonitis, which at the post-mortem examination was found to have been caused by a small rupture of the duodenum; there was also a slight rupture of the liver. At the inquest on the case, the coroner censured the dresser for not having called the house-surgeon to see the man, saying that if it had not been for the careful manner in which he had examined the patient a verdict of manslaughter against the dresser might have been returned. We think in such a case no person in a subordinate position should take upon himself to pronounce an opinion or assume responsibility unnecessarily. Although the house-surgeon might not have recognised the injuries which were shown at the necropsy to exist, and the symptoms of which were so long delayed, still he would probably have admitted such a case and watched for their development.

THE DIMINISHING USE OF ALCOHOL.

WE share the satisfaction of all our contemporaries in reflecting on the significance of a less expenditure on alcohol. The expenditure on drink in 1886 was £122,905,785, as compared with £123,258,906 in 1885, or £363,121 less. Ten years before, in 1876, the highest expenditure was reached—viz., £146,288,759, or £4 9*s.* per head, as against £3 7*s.* 8*d.* in 1886. It is deeply to be regretted, however, that the diminution in one year is not more than £363,121, in spite of all the teaching of medical science and personal experience. Not only is the diminished amount drunk still enormous, but it is drunk by an ever-diminishing number of persons. For there is an ever-increasing number of persons who either totally abstain or drink exceedingly little. It is drunk, too, in a wrong way. All casual drink-

Digitized by Google

ing, drinking on an empty stomach, is bad, and makes directly for disease. We must be thankful for any improvement, however slight. But the disease implied in the consumption of nearly 123 millions of money's worth of alcohol is enormous. A recent return to Parliament shows a steady and large decrease of alcohol consumption in workhouses. In the year ending Michaelmas, 1871, the total cost of intoxicants used in workhouses in England and Wales was £82,554. The cost for 1885 was £44,820. In some workhouses with a large number of inmates, as Wandsworth, Lambeth, and Bethnal-green, no intoxicants at all were used. Similarly with several provincial workhouses. It cannot be too much impressed on guardians that there should be no interference with the medical officers in regard to the prescription of alcohol for the sick, nor upon the medical officers that theirs is the responsibility of prescribing it with care. The Parliamentary returns show that in workhouse practice, as in private, the profession is alive to its responsibilities.

THE HOXTON MURDER CASE.

We imagine there are few persons who will demur to the finding of the jury in this case at the Central Criminal Court, for, guided by the light of the existing law of this country, there was abundance of evidence to show that Currell was guilty of the crime of wilful murder. It is true there was no direct or personal evidence against him, but the indirect or circumstantial was so complete and consistent that no doubt can be left in the inquiring mind that the verdict was fully warranted by the testimony. The convict on the day of the murder borrowed a key of the house where his sweetheart, the deceased woman, then lived. Shortly afterwards, when accosted by an acquaintance with the fact of the death, he replied, in answer to the observation "This is a serious matter for you," "Yes, it is." At the same time he showed no concern to learn the circumstances surrounding the death of Lydia Green. His purloining deceased's wages from her fellow-workpeople, together with his subsequent flight, can only be explained on the theory of his guilt. But, putting on one side the bearings of the legal technicalities of the case, we find ample grounds to warrant us in affirming that the crime was not wilful murder as understood by the medical jurist. That Currell knew the nature and consequences of the act he was about to commit we do not attempt to dispute, but that he was of sound mind and understanding we feel justified in denying. There is scarcely a murder trial of the kind under review in which the presiding judge does not brush against the tangled thicket of law and alienism, and in the recent gaol delivery at the Old Bailey Mr. Justice Grantham, although impartial in his summing up, managed, we assert, with all respect, to run counter to the laws that govern mental science. His lordship remarked in his charge to the jury: "The absence of motive of anger, or of passion, or of any wrong to be revenged only increases the enormity of your crime." This sentence would meet with our approval were it justifiable to assume that all the facts underlying the crime were known (and who can doubt that many were hidden in the minds of the murderer and his victim?), and still more that Currell was at the time free from impulses ungovernable by an impotent will. As regards motive, we are entirely at one with the learned judge, for in few instances can the act of murder find a commensurate excuse, and, as a rule, it is idle and futile to endeavour to fathom the causes of capital crime where the evidence is only circumstantial. We trust the Home Secretary will order a medical commission to inquire into Currell's antecedents and his present condition. The justification for such a procedure may be found in Mr. Justice Grantham's weighty remark: "*It may be that you committed this murder in some unaccountable and irrational state of mind.*" We are no advocates for allowing crime to go unpunished, but it is our bounden duty to plead that life shall not be taken except in cases in which there is the clearest and fullest proof that it has, in the most unqualified sense of the term, been wilfully sacrificed by the accused. It must be proved beyond all reasonable doubt that Currell's "*peculiar temperament*" cannot be translated as his uncontrollable impulse, before the sheriff and the hangman have carried out the last scene in the drama of the convict's miserable existence. Both Mr. Davies, who was called to see the deceased woman shortly after the murder, and Dr. Burchell, who conducted the post-mortem examination, were censured by the judge: the former for neglecting to investigate the case more fully, and for hastily assuming that the wounds might have been occasioned by a fall; and the latter for having trusted to his memory for facts observed at the necropsy. In extenuation of Mr. Davies's mistake, we believe it may be urged that he was called from a case of labour that demanded his presence. Dr. Burchell's error was venial; nevertheless, it may be pointed out that no circumstances connected with an alleged murder are too trivial to be recorded at the time of observation. It is too much, however, to expect from a man engaged in busy general practice what may appropriately be demanded from an expert pathologist and professed medical jurist.

MUMPS AND PERIPHERAL NEURITIS.

Many diseases not strictly speaking of nervous nature have now been found to be associated with peripheral neuritis. Phthisis, typhoid fever, diphtheria, and other febrile diseases are the best known of these. Mumps may be added to the list on the authority of M. Joffroy. The paralysis that occurred in Joffroy's case affected all four limbs. The legs, as usual, were first affected. Lancinating pains preceded the paralysis. The deep reflex actions were abolished. The muscles gave the reaction of degeneration when tested with the faradaic and voltaic currents. The muscles appeared to be increased in sensitiveness, for slight pressure caused pain. The paralysis was observed first three weeks after the onset of the mumps. Is it necessary to ask whether the case was one of true mumps? Mumps is certainly complicated and sometimes followed by cerebral paralysis. In M. Joffroy's case the paralysis endured for four months. Iodide of potassium was the medicament administered.

THE HYGIENE OF OCCUPATIONS.

The hygiene of occupations has been attracting the attention of the State Board of Health of New Jersey, who have, as a preliminary to the study, set forth the general considerations involved in a paper by Dr. E. M. Hunt. He is followed by Dr. J. W. Stickler, who, after having dealt in detail with the various processes included in hat-making, finds that from the beginning, when the different furs are dealt with in the mixing and blowing room, to the end, when the finishers take up the manufacture, certain diseases, and especially affections of the respiratory organs, are liable to be induced. In fact, out of a total number of 722 hatters, the cause of whose death could be accurately determined, no less than 51·8 per cent. died of pulmonary phthisis, and 63·5 per cent. of some form of lung lesion. The next subject of work is that of silk, flax, and jute, which is taken up by Dr. W. K. Newton. As regards silk, he would strongly discourage weaving in dwelling-houses, where the loom or reel is often set up in an already overcrowded kitchen or living room; but he holds that if factories could be built and maintained so as to afford proper lighting, heating, and ventilation, the silk manufacture ought to be a healthful one. In the case of flax and jute, the hackling process, for which no satisfactory machine has been invented,

Digitized by Google

fills the air with dust made up of dirt and minute fibres, leading to paroxysms of coughing and often to early death. The spinning process charges the air in much the same way, the hair and clothing of the operatives being covered with the dust. Hemp and flax dressers inhale a dust that is peculiarly irritating, and the processes generally tend to destruction of the lung tissue in some form or other, and lead to a high mortality amongst the workers. Fans are stated but rarely to effect a proper change in the state of the air, and hence some form of air-filter over the mouth is recommended. In wet-spinning, the air, instead of containing dust, is loaded with moisture, which drops like a fine mist on the operatives, who are practically subjected to a vapour bath—an arrangement provocative of bronchial and other catarrhal affections, as also of rheumatism. The diseases occurring in the manufacture of rubber boots and shoes are considered by Dr. J. P. Davis. After a description of the processes of this trade, it is pointed out that the greatest danger attends the compounding process, in which a large quantity of white lead, litharge, &c., is mixed with the rubber or gum, lead-poisoning being especially frequent during moist hot seasons in summer, when the factory windows have to be kept carefully closed. The heat and want of ventilation are also very injurious. The other conditions leading to mischief are the introduction of naphtha into the cauldron of liquid; the machinery, with resulting accidents; and the fixing of the rubber when completed on to the heels and soles of the boots and shoes, the last being pressed against the pit of the stomach. It is to be hoped that the series commenced in this report will be extended to other trades.

GLASGOW UNIVERSITY CLUB, LONDON.

WE understand that the Marquis of Lothian, Secretary of State for Scotland, and Lord Watson, who was formerly the representative of Glasgow University in the House of Commons, will be the guests of this Club at their approaching dinner on April 29th (Graduation Day), when the chair will be taken by Professor Gairdner of Glasgow. The Club now consists of upwards of 100 members, and as it is constituted entirely with a view to such social meetings, and to maintaining in London the *esprit de corps* and associations connected with their *alma mater*, it seems probable that there may be many men in various walks of life who would desire to become members, but whose names have escaped the notice of the council. The inaugural dinner of the Club, at which Professor Sir W. Thomson presided, took place in October last, at the Holborn Restaurant. The honorary secretaries are Dr. Heron, 57, Harley-street, W., and Mr. McIlraith, 3, Furnival's-inn, W.C.

THE SANITARY STATE OF AVONMOUTH.

THERE is a stage in the history of towns and communities when their future prosperity is either made or marred, and in no respect is this more true than as regards their healthiness. For commercial and other reasons people begin to aggregate on sites which would not otherwise be selected as suited for the growth of towns; and where such sites have from the first been a primary care of the local sanitary authority, being at once supplied with adequate means of sewerage, water-supply, and other sanitary requisites, prosperous places and healthy communities have in the end resulted. Where the first beginnings of towns have been neglected, or, to a large extent, looked on with indifference, the reverse has been the case, and in the end such localities have either attained an unenviable notoriety for their unhealthiness, or it has taken many thousands of pounds to secure mere comparative healthiness in places where a few hundreds at the onset would have been far more successful. Avonmouth, not far from Bristol, is one of these growing towns; its docks are already attracting the favour of ocean steamers, a new dry dock is in contemplation, and about a thousand people are already established there. It has not been altogether neglected. Indeed, a system of sewerage has been established, and it would appear that modern building bye-laws are in operation there. But a system of sewers in a low-lying spot which does not take away the contents of large "rhines" of stagnant water, and which is so contrived that the lowest floors of houses cannot be adequately drained into it, is not such a system as is needed for a growing community. If there be one thing above another that is requisite in sewerage systems, it is that there should be a proper fall from the lowest floor of all dwellings to the sewer, and that the sewer should pass at a proper fall to its outlet. Neither of these essential requisites exists at Avonmouth, and hence, instead of this locality, which has grown up during a period of unexampled sanitary opportunities, being typical of that which is called for by modern health requirements, it is, in the words of Dr. Crossman, the local medical officer of health, the weakest point in his district. We have referred to the existence of building bye-laws in Avonmouth, but it is well known to those who are concerned in sanitary administration that such bye-laws lose their main power for good unless a surveyor is appointed to see to their enforcement; and no such appointment has been made for Avonmouth. There are doubtless other points in which the health requirements of this growing place call for attention, but we have only noted the great need for a proper system of sewerage and outfall, and for proper control over building operations, as types of that class of work which in all such places can ensure future healthiness if they are properly carried out at an early stage, whereas sickness and disease are sure to ensue sooner or later if they are neglected. There is no time like the present for initiating measures which are to influence the sanitary history of growing communities.

THE PRIVY COUNCIL AND THE MEDICAL ACT OF 1886.

THE *London Gazette* of April 1st contains an order of the Queen in Council declaring that on and after the first day of June, 1887, the second part of the Medical Act shall be deemed to apply to New Zealand.

THE ANATOMICAL SOCIETY.

As we announced some time since, steps are being taken towards the foundation of an Anatomical Society. It is proposed that the scope of the new Society shall be "Human and Comparative Anatomy, Embryology and Histology, so far as they bear upon Human Anatomy." The project is receiving influential support from authorities in England, Scotland, and Ireland. An inaugural meeting, at which Professor Humphry has consented to take the chair, will be held towards the end of the present month, at a place and time to be announced in due course. Mr. C. B. Lockwood, of 19, Upper Berkeley-street, W., is acting as hon. sec. *pro tem.*, and will be glad to give information to anyone who is interested in the movement.

REGISTRATION UNDER OLD DIPLOMAS.

THE uncertainty of the exact bearing of the Act of 1886 on the conditions of registration after the appointed day in June, and the opinion of the solicitor to the General Medical Council (see p. 747) thereanent, induce us to advise all persons entitled to registration on old qualifications to register without delay. One of the most probable consequences of the new Act will be to raise legal questions more likely to benefit the sister profession than our own.

Digitized by Google

THE HEALTH OF THE SPEAKER.

WE are glad to be able to announce that the health of the Right Honourable the Speaker of the House of Commons is progressing favourably. We learn that on Saturday, the 26th ult., after the repeated long sittings of the House, he was much exhausted, and on the following day he experienced a severe attack of cramp of the right leg, which was followed by swelling and tenderness in its middle and lower thirds, indicating some lymphatic disturbance. There is little doubt that the harass and anxiety inseparable from his official position have been much augmented by the recent disturbed condition of political affairs, and have been too great a strain upon his usual good health. The right hon. gentleman has been attended by Mr. G. W. Mackenzie, of William-street, Lowndes-square, and on Wednesday morning was sufficiently recovered to leave London for Sandy, his country residence in Bedfordshire. He has leave of absence until the middle of next week, when he is fully expected to be able to resume his Parliamentary duties.

TORTURING TURTLES.

IF it were not cruel—which it is, and hideously so—to bring over turtles in a dying state, it would be wantonly wasteful. We wonder that the aldermanic conscience—which is popularly believed to be located within the area of the gastric organ—has not long ago rebelled on behalf of the poor turtles thus tortured. Of course the animals ought to be either killed and packed in ice, or preserved in tanks. The turtle is not so common a stock-in-trade as to be necessarily "bulked" in carriage. The waste is large, and the quality of the meat is wofully deteriorated by the way it is tumbled about and mauled *en route*. If to these drawbacks we add that the sufferings inflicted on the creatures are terrible, it might be thought that the case for prudence and humanity was made out—but is it?

ABUSE OF MEDICAL CHARITY IN SCOTLAND.

A MEETING of medical practitioners was lately held in the Faculty Hall, Glasgow, Dr. James Morton, President of the Faculty, occupying the chair. He and various speakers descanted on the abuse of medical charities, both infirmaries and dispensaries. Dr. Macleod was especially emphatic in complaining that even well-to-do people came to the infirmary, and even as in-patients. "He had," he said, "some farmers in his wards, who farmed six or seven hundred acres of land. They would come up with lines from doctors recommending them. The medical profession was immensely at fault in this. They suffered greatly by these letters from doctors." We feel bound to reproduce these words, and hope to have some refutation of them from Scottish practitioners. Practitioners are well within their rights in representing to their consulting brethren the means of their patients, with the view of getting for them that consideration which the best consultants are ever ready to give. But infirmary beds are not meant for those who farm six or seven hundred acres. The Scotch boast, and properly, of their independence, but in all the literature of abused charity there is nothing worse than the accounts of abused medical charity in Scotland. Dr. John Brown in "Our Gideon Grays" quotes from the Appendix to the Report of the Board of Supervision the results of the inquiries of a voluntary association of medical men formed in Edinburgh, with the public-spirited Dr. Alison as chairman. The inquiry had reference to the remuneration of doctors among the paupers. One man attended 400 paupers for eight years and never received one farthing for his skill, time, or drugs. Another has the same story to tell of 350, some of them thirty miles off. He moderately calculates his direct loss from these calls on his time and purse at £70 a year. Verily, ours is a benevolent profession. But our benevolence, like that of Dr. Alison himself, has been overdone, and is bad for the public and the poor. A committee was appointed to consider and report on the best means of preventing abuse and overlapping of medical charity.

PERTH INFIRMARY.

IN the issue of THE LANCET for April 2nd it was stated that eight directors of the Perth Infirmary had resigned in consequence of the strained relations between the board of directors and the medical officers of the institution. It seems that the only strained relations existing were between Dr. Bramwell and the directors. The latter had deemed it wise to promote Dr. Bramwell to the consulting staff after nineteen years of service as a visiting surgeon. Dr. Bramwell did not wish to resign his position on the visiting staff, and at a meeting of subscribers his supporters passed a vote of censure, in consequence of which eight directors resigned. Another meeting of subscribers has since been held, at which the directors who had resigned were re-elected unconditionally by an overwhelming majority. The relations between Messrs. Christie, Stirling, Graham, Calder, and Hunt, the medical officers of the Perth Infirmary, and the directors have, we understand, always been of a most friendly nature.

"BRAIN."

ARRANGEMENTS have been made between the Council of the Neurological Society of London and the editorial committee and publishers of *Brain*, in virtue of which the journal has become the organ of the Society. The publishers, Messrs. Macmillan and Co., have undertaken the whole financial responsibility of the journal, which will henceforth be regularly sent free of charge to every member of the Society. The editor is Dr. de Watteville, who has fulfilled the post of acting editor for many years past. The next number of *Brain* forms the first part of the new tenth volume, and will contain Dr. Bastian's important paper on the Muscular Sense, with the discussion thereon.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Don Manuel Rioz Pediaja, Professor of Chemical Analysis as applied to Medicine in the University of Madrid, who had held the offices of Dean of the College of Pharmacists and of Rector of the University. Dr. Gustav Kempner, *privat-docent* of Berlin. Dr. Julius Wolff, one of the medical officers of the Policlinic in Breslau. Dr. Jean Kickx, Professor of Botany and Director of the Botanic Gardens in Ghent.

VACCINATION AND DISTEMPER.

M. DUPUIS of Brussels has made a number of observations for the purpose of ascertaining the effect of vaccination on puppies, with special reference to its power of protecting them from the distemper. He found that it was quite possible to inoculate them with vaccine, but that it had no protective influence against distemper.

THE TREATMENT OF PHTHISIS BY ANILINE.

THE commission which was appointed by the second congress of Russian medical men at Moscow to examine the treatment of phthisis by aniline, as proposed by Professor Kremianski, has, after experimenting on a number of animals who were fatally affected by even small doses of aniline, and after some little trial in the wards, come to the

Digitized by Google

conclusion that aniline is not harmless to animal life, but on the contrary, very poisonous indeed, and that it also exerts no beneficial effect at all on phthisis.

FOREIGN UNIVERSITY INTELLIGENCE.

Basle.—Dr. Fehling, Director of the Stuttgart School for Midwives, has been appointed Professor of Midwifery.

Berlin.—Professor Karl Möbius of Kiel will take up the duties of the chair of Zoology after Easter.

Bordeaux.—M. Blarez (*agrégé*) has been appointed Professor of Chemistry.

Cracow.—Professor Hofmokl of Vienna has refused the invitation to Cracow on account of the wretched condition of the surgical clinic. The names of Drs. Rydygier and Obalinski are now mentioned in connexion with the vacant surgical chair.

Giessen.—Dr. Spangel, Director of the Town Museum of Natural History, has been appointed Professor of Zoology.

Helsingfors.—Dr. Holsti has been appointed Extraordinary Professor of Internal Pathology, and Dr. E. Sundvik Extraordinary Professor of Physiological Chemistry and Pharmacology.

Innsbruck.—Dr. Borysiekewicz of Vienna has been appointed Professor of Ophthalmology.

Lyons.—M. Laroyenne, who takes one of the gynæcological courses, has been appointed Professor-adjoint. M. Perroud, who takes one of the courses on children's diseases, has also been appointed Professor-adjoint.

Munich.—Dr. Karl Schloesser, Assistant in the Ophthalmic Clinic, has become *privat docent*.

Nancy.—M. Hergott (*agrégé*) has been appointed Professor of Midwifery. M. Spilmann (*agrégé*) has been appointed Professor of Clinical Medicine.

Rouen.—Professor Duménil has been appointed Director of the Preparatory School of Medicine.

Tomsk.—The Medical and Physico-Mathematical Faculties of this the new Siberian University are to be opened this year.

Toulouse.—M. Charpy has been appointed Professor of Anatomy, in succession to M. Bonamy, deceased.

Vienna.—Professor Max Gruber of Graz has been appointed Extraordinary Professor of Hygiene. It has been decided that the vacation courses are only to be open to foreign medical men in cases where the full number of the classes is not made up by Austrians. This may prove rather a serious matter for some of the English and Americans who frequent the Vienna Hospital for the short courses, for which it is famous.

Würzburg.—Dr. Matterstock has been selected by the Senate as successor to Professor Geigel, the recently deceased Professor of Medicine.

AT the Belgian Royal Academy of Medicine there has been a warm discussion for some time past on the subject of the State regulation of prostitution. M. Moeller, in support of his objections to the principle of regulation, attempted at a recent sitting to show by reference to English statistics that such regulation was not only useless, but actually hurtful. M. Crocq, however, from the very same statistics, proved that the cases of contagion in the British army were less numerous by one-half in the localities where the Contagious Diseases Acts were in force than in other garrison towns.

THE lectures at Gresham College, Basinghall-street, will be delivered by Dr. Symes Thompson on the 19th and three following days of the present month. The subject will be "The Blood." It is hoped that the course will be continued on Oct. 4th, 5th, 6th, and 7th.

ON the 4th inst. Mr. Ritchie received a deputation at the Local Government Board from eleven unions and boards of guardians, representing all the great military and naval centres, who urged that the law should be amended so as to enable them to detain in their infirmaries patients suffering from disease until cured. Mr. Ritchie, in reply to the representations of the deputation, said that he did not know whether Lord Devon's Act, which enabled the guardians to detain persons suffering from "contagious disease," could be applied to these cases; but he would obtain the opinion of the law officers of the Crown upon the point, and would communicate their opinion to the various boards of guardians.

THE captain of the ship *Belpore* of Liverpool, which arrived in the Tay from Calcutta on the 31st ult., reported to the Customs officers who boarded the vessel the deaths of two of the crew from cholera during the homeward passage. The vessel was moored at the quarantine station, and a thorough disinfection by the sanitary authorities was ordered previously to her coming into port.

THE Norwegian Government has taken another step towards discovering the origin and nature of leprosy, which is so common on the west coast of Norway, by despatching Dr. G. A. Hansen, director of the Leprosy Hospital at Bergen, to North America, for the purpose of inquiring into the heredity of the disease among Scandinavian emigrants to the United States.

DR. SINCLAIR COGHILL of Ventnor has been elected Vice-President of the International Medical Congress to be held at Washington on Sept. 5th proximo.

AT Braintree, in consequence of the extensive prevalence of measles in the town and neighbourhood, several of the schools have been closed.

THE trustees of St. Bartholomew's Hospital, Rochester, have declined to reopen the lock ward of that institution.

ROYAL COLLEGE OF PHYSICIANS.

A COMITIA of the Royal College of Physicians was held on Monday last, the 4th inst., the President, Sir W. Jenner, Bart., in the chair. There was a large attendance of Fellows.

A communication was read from the Colonial Office requesting information upon the contagiousness of leprosy. The subject was referred to a special committee consisting of Sir Risdon Bennett, Sir J. Fayrer, Dr. R. Liveing, and Dr. Stone.

It was resolved to erect a statue of the Queen in the new Examination Hall, in conjunction with the Royal College of Surgeons.

The adoption of the report of the Croonian Committee was moved by Dr. Quain, seconded by Sir E. Sieveking, and carried. The report, which was based on resolutions of the College passed on June 29th, 1886, recommended the following regulations:—"1. That the Croonian lecturer be appointed annually by the President and Censors for the purpose of delivering a course of not less than four lectures on subjects embraced in No. 1 of the above resolutions. 2. That the lecturer be paid 100 guineas for the lectures, and that the remainder of the Croonian Trust fund be employed for original investigation by a past or present Croonian lecturer. 3. That the lecturer, who must be a Fellow in accordance with the original trust, shall be eligible for reappointment. 4. That the subjects of the lectures and investigations be selected with the approval of the President and Censors. 5. That the lectures be delivered in the month of June, and that the first course of lectures be given in 1888."

The President then addressed the meeting upon the

Digitized by Google

affairs of the College during the past year, and gave an account of the career of the six Fellows who had died since the last annual meeting—viz., Drs. Wiltshire, Nairne, Farre, Chadwick, Moxon, and Carrington.

The election of President was then proceeded with, and the choice again fell upon Sir W. Jenner, who was formally inducted into the office by the Senior Censor.

MEDICAL REGISTRATION AND THE NEW ACT.

IN view of the possibility of some (perhaps many) who possess registrable qualifications not being aware of the full bearings on registration of the Medical Act (1886), a letter, of which the following is a copy, has been forwarded to all the medical licensing bodies in the United Kingdom:—

"Sir,—I am directed by the President of the Medical Council to forward to you, for the information of ——— ———, the following statement, which has been prepared for him by the solicitor to the Council:—

"'After the 1st of June, 1887, no person can be put on the Medical Register by virtue of a single qualification, such as a diploma in surgery or a diploma or licence in medicine. Up to the 1st of June next any person can be put on the Register by virtue of such single qualification, and being once on, he may obtain additional qualifications by subsequent examinations, and such additional qualifications may be added to or substituted for those already on the Register. But after the 1st of June next no one can be put on the Register who has not passed the qualifying examination required by the Act of 1886—that is, an examination in medicine, surgery, and midwifery, and these three subjects must be taken up together; hence anyone who has now a single qualification, and intends to obtain further qualifications after the 1st June next, should take care to be on the Register before that day, for if he is not on it, his single qualification will not afterwards entitle him to registration.'

"As the subject is of importance to many persons who have not yet completed their medical education, you will doubtless think it desirable to give the statement such publicity as you may see fit, for the information of candidates for your examinations. "Yours faithfully,

"W. J. C. MILLER, Registrar.

"General Medical Council Office, 299, Oxford-street, London, W."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Caxton and St. Neots Combination.—Mr. Poyntz Wright acts for two rural areas and one urban district. So far as he has had opportunity of judging the water-supply, he is of opinion that the wells are frequently contaminated with organic and sewage matter by reason of the dangerous proximity of privies and cesspools fouling the subsoil, and he points out the risks which such a system involves. He also advises the abolition of cesspool privies and their replacement by earth-closets or pail-closets. He also advocates in certain places cesspool drainage in safe positions, with an overflow into a water-course. This, we fear, is unsafe advice, involving as it does fresh pollution of streams, and absolute breach of Section 47 of the Public Health Act, in so far as the urban district is concerned which is named at the head of the chapter, if indeed this district was intended to be included. The St. Neots rural authority have, on Mr. Wright's suggestion, adopted a voluntary system of notification of disease, but the urban authority objected to carry out such a system, on the ground that the medical attendant on such cases rendered unnecessary, by his action, any interference on the part of the health officer. Such reasoning would, if carried to its proper extent, lead to the abolition of the clauses of the Public Health Act as to the prevention of infection in all cases where a doctor was called in; but this was certainly not the intention of the Legislature. Dealing in other chapters separately with each district, it appears that in St. Neots much well-water is dangerously circumstanced, and weekly scavenging is called for, together with improvement in closets and in dealing with slop-waters. In the Caxton rural district good water will soon be available for several places from water-works to be erected at Bourne. In the St. Neots rural district improvements have been made at Grafham as to water-supply, and at Eaton Socon the sewage irrigation answers well; but at Kimbolton a similar system would appear to have resulted in failure, owing to the land receiving more sewage than it can possibly take up.

Helmsley Rural District.—In the Helmsley division of this union the population is 3961, and it had in 1886 a death-rate of 12·1 per 1000. There was no scarlet fever or measles during the year, and only 3 cases of enteric fever came under notice. The history given as to these by Dr. Bruce Low shows how carefully each such occurrence is investigated with a view to preventive action. It is somewhat curious that 61 cases of diarrhœa occurred at Pockley in this district; the details were sent to Dr. Ballard in connexion with his official inquiry into diarrhœa prevalences. The general immunity of this district from dangerous infection may perhaps induce the authority to postpone providing the means of isolation and disinfection which Dr. Low advocates, but it is precisely during the absence of emergencies that these matters should be dealt with. It is satisfactory to record a marked diminution in illegitimate births and in deaths amongst such children, especial attention having been devoted to this subject in the district, and wide publicity having been given to the evils and cruelties heretofore attendant on illegitimacy. Questions of overcrowding, water-supply, and other matters are dealt with as they rise.

Clitheroe Urban District.—The birth-rate for this district in 1886 was 28·8 per 1000, the death-rate 17, and the zymotic rate 1·5. The current work of the year included the gradual removal of open midden-privies, 170 having been abolished in favour of the tub system. Action is also being taken towards securing the slaughtering of animals in wholesome places, and in certain instances any further slaughtering in existing places was prohibited. It is also stated that as the present time there are but few instances in which there is any direct communication between houses and drains in the Clitheroe district. In the Low Moor district matters are by no means so satisfactory; and whereas in Clitheroe reduction of mortality is shown, no such diminution is observable in the Low Moor. In the former, for example, the infantile death-rate is distinctly less than in the latter. Mr. J. J. Fraser also shows that where sanitary improvements have been effected infectious diseases have diminished.

St. Asaph Rural District.—With a death-rate of 18·0 per 1000, Dr. Lloyd-Roberts is of opinion that deaths are not excessive; but whilst there may not be much to complain of, there is, in our opinion, still room for improvement in this respect in such a district. Diphtheria has often been a perplexing disease in this portion of North Wales, and it was last year scattered through six parishes in this rural district. In St. Asaph itself infection is conveyed from the upper to the lower parts of the city by the river Elwy, which acts as a source of water-supply for the latter area. But we read, as regards the district generally, that no new public works for sewering or water-supply have been undertaken. At Prestatyn such works are imperatively called for, the district being one which bids fair to become a growing watering-place.

Pwllheli Urban District.—In this district the death-rate for 1886 was 18·13 per 1000. Early in the year small-pox called for energetic action, and, owing largely to the available hospital accommodation, the disease was checked. Out of 21 cases 3 were unvaccinated, and of these 2 died; whereas no case occurred in a revaccinated person. Mr. Lawton reports that he has maintained systematic inspection of the district, and he shows how such matters as scavenging and water-supply have been supervised, and how slaughter-houses, common lodging-houses, and bakeries, &c., are controlled.

VACCINATION is, it is stated, to be enforced among all the workmen employed on the coming Paris Exhibition. Each man will be vaccinated as soon as engaged, and the Government will not only pay for the necessary medical treatment, but will continue the man's wages should his arm become bad and prevent him from working.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6022 births and 3831 deaths were registered during the week ending April 2nd. The annual rate of mortality in these towns, which had increased in the preceding seven weeks from 19·5 to 23·5 per 1000, declined again last week to 21·6. During the thirteen weeks of the first quarter of this year the death-rate in these towns averaged 20·0 per 1000, and was 2·2 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 14·6 in Brighton, 17·2 in Bradford, 18·8 in Birmingham, and 19·3 in Portsmouth. The rates in the other towns ranged upwards to 28·7 in Manchester, 30·7 in Huddersfield, 32·5 in Plymouth, and 33·1 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the preceding seven weeks from 340 to 465, further rose last week to 471; they included 239 from measles, 105 from whooping-cough, 37 from scarlet fever, 32 from diphtheria, 32 from diarrhœa, 25 from "fever" (principally enteric), and only 1 from small-pox. These zymotic diseases caused the lowest death-rates last week in Birkenhead and Bolton; and the highest rates in Oldham, Sunderland, and Huddersfield. The greatest mortality from measles occurred in Sheffield, Cardiff, Liverpool, Newcastle-upon-Tyne, Bristol, Oldham, Manchester, Huddersfield, and Sunderland; and from whooping-cough in Bristol, Huddersfield, and Blackburn. Of the 32 deaths from diphtheria in the twenty-eight towns, 14 occurred in London, 4 in Liverpool, 3 in Bristol, 3 in Oldham, 2 in Plymouth, 2 in Birmingham, and 2 in Manchester. Small-pox caused one death in Portsmouth, but not one either in Greater London or in any of the twenty-six other large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 433, 474, and 509 in the preceding three weeks, declined again last week to 417, and were 127 below the corrected average. The causes of 107, or 2·8 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Wolverhampton, and Huddersfield. The largest proportions of uncertified deaths were registered in Oldham, Salford, Sheffield, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 26·2 and 25·9 per 1000 in the preceding two weeks, further declined to 23·5 in the week ending April 2nd; this rate exceeded, however, by 1·9 the mean rate in the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 11·5 and 18·5 in Leith and Greenock to 28·2 in Paisley and 31·5 in Aberdeen. The 588 deaths in the eight towns last week showed a further decline of 58 from the numbers in the previous week, and included 43 which were referred to measles, 31 to whooping-cough, 18 to diarrhœa, 8 to diphtheria, 6 to scarlet fever, 5 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 111 deaths resulted from these principal zymotic diseases, against numbers increasing from 98 to 127 in the previous four weeks. These 111 deaths were equal to an annual rate of 4·4 per 1000, which exceeded by 1·7 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had increased in the preceding four weeks from 27 to 55, declined last week to 43, of which 34 occurred in Aberdeen and 8 in Glasgow. The 31 deaths from whooping-cough corresponded with the number in the previous week, and included 12 in Glasgow, 11 in Edinburgh, and 5 in Dundee. The 18 deaths attributed to diarrhœa showed a further increase upon recent weekly numbers; 10 were returned in Glasgow and 4 in Dundee. The 8 deaths from diphtheria included 3 in Glasgow, 3 in Edinburgh, and 2 in Paisley. The 6 fatal cases of scarlet fever, of which 3 occurred in Glasgow and 2 in Edinburgh, showed a decline of 12 from the number in the previous week. The 5 deaths [illegible] fever," an increase of 2 upon the low [illegible] week, [illegible] deaths from the eight towns, which had been 152 and 146 in the preceding two weeks, further declined last week to 132, and were 2 below the number in the corresponding week of last year. The causes of 67, or 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 29·3 and 31·3 per 1000 in the preceding two weeks, was again 31·3 in the week ending April 2nd. During the thirteen weeks ending last Saturday the death-rate in the city averaged 30·9 per 1000, the mean rate during the same period being but 20·7 in London and 21·6 in Edinburgh. The 212 deaths in Dublin last week corresponded with the number in the previous week; they included 6 which were referred to "fever" (typhus, enteric, or simple), 4 to measles, 4 to scarlet fever, 3 to whooping-cough, 1 to diarrhœa, and not one either to small-pox or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 10, 7, and 18 in the preceding three weeks, were again 18 last week; they were equal to an annual rate of 2·7 per 1000, the rates from the same diseases being 2·0 in London and 3·8 in Edinburgh. The deaths referred to "fever" exceeded the number in any recent week, while those from scarlet fever showed a decline of 3 from the number in the previous week; the fatal cases of measles and whooping-cough corresponded with the number in the previous week. The deaths of infants exceeded the number in either of the previous two weeks; while those of elderly persons showed a decline. Four inquest cases and 5 deaths from violence were registered; and 69, or nearly a third, of the deaths occurred in public institutions. The causes of 29, or nearly 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

MEDICAL REGULATIONS.

ALTERATIONS in and additions to the Regulations for the Army Medical Department have been approved, and will be issued to those concerned.

A Greenwich Hospital Pension of £50 a year for Fleet and Staff Surgeons has fallen vacant by the death of Retired Fleet Surgeon Gerald Yeo, F.R.L.S., who had been a recipient of the same since May 21st, 1881.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Wm. Alex. Gardiner is granted retired pay, with the honorary rank of Deputy Surgeon-General (dated April 2nd, 1887).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets Dugald McEwan, M.D., has been placed on the Retired List.

In accordance with the provisions of Her Majesty's Order in Council of March 25th, 1887, Deputy Inspector-General of Hospitals and Fleets William Henry Sloggett has been granted the honorary rank of Inspector-General of Hospitals and Fleets, in recognition of his services as Inspector of Certified Hospitals (dated March 25th, 1887).

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet:—Herbert Elliott Marsh; Henry George Travers Strickland, M.B.; Alfred Patterson; Michael Ronan, B.A.; John Anderson McAdam; John Dudley, M.B.; and David Brownrigg Bookey.

The following appointments have been made:—Staff Surgeon J. A. McAdam, to the *Penguin* (reappointed on promotion); and Surgeon William George Jack, to the *Forward* when recommissioned, and until then additional.

ARTILLERY VOLUNTEERS.—2nd Durham (Seaham): Surgeon T. C. Beatty, jun., resigns his commission (dated April 2nd, 1887).—Luke Gerald Dillon, M.D., to be Acting Surgeon (dated April 22nd, 1887).

ENGINEER VOLUNTEERS.—2nd Cheshire: Jas. Atkinson, Gent., to be Surgeon (dated April 1st, 1887).

RIFLE VOLUNTEERS.—4th Lancashire: Surgeon and Honorary Surgeon-Major E. H. Roe resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement (dated April 2nd, 1887).—1st Linlithgowshire: John Anderson, M.B., to be Acting Surgeon (dated April 2nd, 1887).—1st London (City of London Rifle Volunteer Brigade): Surgeon J. J. Gawith resigns his commission (dated April 2nd, 1887); Acting

Digitized by Google

Surgeon H. F. Stokes to be appointed Surgeon (dated April 2nd, 1887).—22nd Middlesex (Central London Rangers): Surgeon J. R. Kemp resigns his commission (dated April 2nd, 1887).

Correspondence.

"Audi alteram partem."

THE TREATMENT OF PLACENTA PRÆVIA.

To the Editors of THE LANCET.

SIRS,—I suppose, strictly speaking, that no particular method of managing placenta prævia can claim being *the treatment*, because the conditions which present themselves when we are called to these cases vary very much, and to each variety there is a more appropriate treatment. Besides the two positions of the surroundings I mentioned in my last letter—namely, where we are called without previous knowledge, and secondly, where we have already ascertained the existence of placenta prævia,—there are three main classes:—

1. If the os uteri be well dilated, the placenta extending but a little over the os, and consequently the membranes plainly felt, the rupture of the membranes is the first thing to be done. If turning has been determined upon, then this will be performed at the same time; otherwise we might wait for the natural forces. Should these hesitate, or hæmorrhage continue, ergot, forceps, or version should be employed, according to circumstances. There will be no reason to detach the lower portion of the placenta.

2. Should the placenta, however, be attached nearly or entirely athwart the os uteri, then the detachment of the placenta as far as the fingers can easily reach will have a twofold effect: it will relieve the os from the restriction the adhesion of the placenta caused, and permit consequently its expansion; and it will also for a certain period generally check the bleeding, but not always; sometimes there is a very sharp loss; then the quickest and surest plan is to turn at once and plug the os by the leg or breech; the bleeding then stops, and pains generally arrive in a short period. If, after this separation of the lower portion of the placenta, no bleeding arise, and if we can remain about the patient, the natural forces might be trusted to deliver the patient; should, however, these hesitate, we might elect two plans—either to dilate the os with Barnes' bags, and when the os is large enough to apply the forceps to the head to bring this into the os, or turn and bring the breech into the same position. In either case labour pains usually soon come on. We should keep on the forceps, however, to assist, if needful, till the head is clear. But if, on the contrary, we have neither bags nor forceps at hand, then version by my method gives the patient security.

3. But supposing the os uteri is small, the bleeding severe, and, called on suddenly, we are unable to obtain either dilating bags nor forceps, also unable to leave the patient till delivered: then it is (now that the tampon is for ever, I hope, discarded), even though the os would admit only one or two fingers, that my plan of turning becomes the security of the patient, and being the only treatment possible, and of the most secure kind, it does practically become *the* treatment.

In the second class of cases, when the employment of version becomes necessary from the continuance of hæmorrhage, and both dilators and forceps are absent, and the os being not dilated sufficiently to admit the hand, then my plan of turning becomes *the* treatment, and the patient's security, and, except the *accouchement forcée*, the only security; and these cases, coupled with the third class, form by far the largest number in every-day practice. But the full recognition of the rule for as early a delivery as possible in cases of placenta prævia brings out the advantage which the capability of early version given us by the combined or bipolar method, advancing treatment a considerable stage earlier; and when other methods are not to hand, as I pointed out in 1863-4 in my remarks on Dr. Greenhalgh's paper, and in my work on Combined Turning, there is one advantage in this form of version, that soon after the leg is brought through the os uteri labour pains generally occur, giving time enough for the patient to rally and an early release of the medical attendant. Dr. Lomer points out the ease with which his assistants learnt it, and he thinks they represent very well the average in the profession, the cases reported having been done principally by them. Still, without classifying the employment of version as a routine, practice gives results at present of the most favourable kind. In the conclusion of an unavoidably egotistical letter, I would again urge those engaged in midwifery, while employing all the modern methods of help suitable to each case, to remember the rule, "Deliver as early as possible after the recognition that the placenta is about or athwart the mouth of the womb"; and to this I would add, "Don't leave the patient till she is delivered." As the result of my experience, I have often remarked I would rather handle a case of placenta prævia than one of post-partum hæmorrhage.

I am, Sirs, yours truly,

J. BRAXTON HICKS.

George-street, Hanover-square, April 3rd, 1887.

PASTEUR'S "METHODS."

To the Editors of THE LANCET.

SIRS,—Your issue of Feb. 5th contains a letter by Dr. John H. Clarke, in which he says, "At any rate, the facts should be made known without delay, in order, on the one hand, to remove suspicion from M. Pasteur's treatment, or, on the other hand, to warn possible applicants against the risk it involves." This warning does not come a moment too soon. I have been rather surprised that, in the face of von Frisch's experiments and M. Peter's experiences, THE LANCET has not thought it advisable to warn the profession of the possible dangers of the latest phase of M. Pasteur's treatment—the intensive method. Certain of M. Pasteur's French supporters—especially M. Grancher—are still triumphantly appealing to the formidable list of "cases of cure." But not only is the treatment in those cases founded on a fallacious basis, but it has been abandoned, and, so far as we have particulars, it has been distinctly confuted by crucial experimental test. M. Pasteur has at last been driven to admit the force of an objection, which he should have recognised before committing himself to the treatment of human beings after they were supposed to have been inoculated with rabic virus. This is what he says: "The objection can be brought against the usual protective inoculation of man after a bite, which is based upon the inoculation of dogs before the bite, that the immunity of animals after infection with rabies poison has not been certainly established. To confute this charge it is necessary to make dogs immune after trephining and the intra-cranial inoculation of street rabies. ..... My first experiments on this point took place in August, 1885. The result was a partial success. In the course of the last month I took up these experiments as soon as my duties allowed me time. *The condition of success is this: that the inoculation should begin soon after the infection—i.e., the same day;* that one must proceed with such extraordinary rapidity that the series of *medullæ oblongatæ* made use of may be employed in twenty-four or less hours, and that this treatment must be repeated once or twice every two hours. That Dr. v. Frisch was not successful in similar experiments is to be ascribed to the slow inoculation he employed." I will not now stop to consider whether M. Pasteur does not stand condemned out of his own mouth. As von Frisch has repeated the experiments by the new method, and declares that the procedure is not only *not* successful but possibly dangerous, and as, moreover, M. Pasteur has declared otherwise and admits the transcendent importance of the test, let that point be authoritatively and finally settled. Any appeal to the "cases" in view of M. Pasteur's utterance, to the effect that the condition of success is that the inoculations should be commenced the same day as infection, and with such extraordinary rapidity, is simply idle, as in none of them was that condition observed. Let varying quantities of saliva—diluted if necessary—taken from a rabid dog be injected into healthy ones, and let M. Pasteur operate in half the cases, the other half being reserved as controls; and let this experiment be repeated as often as necessary. M. Pasteur must stand or fall by this test. What, may I ask, would have been the fate of M. Pasteur's method had one of the fatal cases been his first instead of Joseph Meister? Should we have heard any more of it? I imagine not. Unfortunately, the twelve inoculations (six of which were done with subsequently

Digitized by Google

proved innocuous material) accomplished then what thirty-six do not succeed in doing now, and the reputation of the method was established! But, *mirabile dictu*, that very perfect, ever-successful, though unstable method has now been abandoned for a new one. "The three little inoculations" at any time before the occurrence of hydrophobia became twelve within thirty-five days of the bite, reduced suddenly to fifteen days; though the non-fatal cases were all the time vauntingly held up as examples of the success of the treatment. Now we have the latest shift, which affects not only the number of inoculations, but the very intensity of the material itself, and which, according to M. Pasteur's experimental "conditions of success," actually reduces the time to *the day of infection*. Bearing in mind the manner in which the method has undergone so many modifications with a never-failing claim to success, we are brought face to face with the fact that we must accept one or other of the following two conclusions:—(1) That there are degrees of infection, that each method operated efficiently in preventing rabies, and that there was a marvellous adaptability between the degree of infection and the method adopted in each case; or (2) that in the rare cases in which infection occurred the inutility of the particular method had recourse to was demonstrated, and a change of method was accordingly adopted. Which, may I ask, is the more reasonable conclusion? It is pitiable to see the intolerance with which M. Peter's efforts to lay bear the truth are met by M. Pasteur's partisans; but the time will surely come when he will make himself heard not only within the walls of the Académie de Médecine, but in every corner of the earth where M. Pasteur's fame has reached.

I am, Sirs, yours faithfully,

Goalundo, March 1st, 1887. VINCENT RICHARDS.

THE CASE OF LENNARD *v.* BROWN AND ALLATT.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of the 5th ult. there was a leading article dealing sympathetically with the case of Lennard *v.* Brown and Allatt, in which an attempt was made to prove adultery against a medical co-respondent. This attempt broke down entirely, and Mr. Brown was absolutely exonerated alike by the summing-up of the judge and by the verdict of the jury. The petitioner has no means of paying the costs which Mr. Brown has incurred in defending himself, and these amount to the sum of £160 18*s.* 11*d.* We think the case is one in which other practitioners may be fairly asked to assist Mr. Brown in bearing the expenses which have thus been forced upon him. But he felt it to be a duty to resist the attempt, to which any other member of the profession might be exposed, and in thus deciding he was fighting the battle of the profession as much as his own. We trust that you will render us your valuable assistance in bringing forward this aspect of the case, and that you will be induced to take charge of any fund which may be raised for the purpose indicated.

We are, Sirs, yours truly,

ROBERT BARNES,
SYDNEY JONES,
W. H. BROADBENT.

April, 1887.

*** We understand that Dr. Murray, of Meadowside, Upper Richmond-road, Putney, has expressed his willingness to receive subscriptions towards a fund for the purpose intimated in the above letter.—ED. L.

"A VICTIM OF THE LAW."

To the Editors of THE LANCET.

SIRS,—The letter which appeared in THE LANCET of March 19th with the above signature discloses a case which seems to me to call for some practical sympathy from members of our profession. The writer tells us that, in compliance with a magistrate's order (which, I presume, he was bound to obey), he examined and certified to the insanity of a patient who, in consequence of his certificate, was consigned to a lunatic asylum. On regaining her liberty, she brought an action against the medical man who signed the certificate; and though the verdict was given in his favour, he is now called upon to pay costs to the sum of £240, the plaintiff professing herself a pauper. [illegible] ill-paid profession few can, without serious inconvenience, if not actual hardship, bear such a strain on their resources; and if you, Sirs, would open a subscription list for the unfortunate "victim," whose name is, I presume, known to you, I feel sure that many of his professional brethren who have happily escaped such vexatious actions themselves will show their thankfulness by helping to indemnify him for his pecuniary loss. In "mind and body" he has doubtless suffered much; it should be the care of his brother practitioners that he does not suffer in "estate" also.

I am, Sirs, yours truly,

Petersfield, March 28th, 1887. A. W. LEACHMAN, M.B.

*** At the moment of going to press, we learn that the Metropolitan Counties Branch of the British Medical Association have opened a subscription list for the object mentioned above, and that donations towards the fund may be forwarded to Mr. George Eastes, M.B., 69, Connaught-street, Hyde Park. The amount given or promised has already reached nearly £40. We need scarcely say that the movement has our hearty sympathy.—ED. L.

THE DRAINAGE OF THE MONTE CARLO CASINO.

(From our Special Correspondent.)

IN a previous letter the condition of the sewers of Monaco was described and criticised, but tourists are more interested in the drainage of the Casino than of this antique town. Most visitors live in the district of Monte Carlo or of the Condamine. There is only one very small and modest hotel available at Monaco. Tourists go up to Monaco to see the Palace, the small museum, the quaint streets of the old town, and the very beautiful garden at the extremity of the rock. To the naturalist this garden is interesting as a contrast to the Casino gardens, situated on the opposite hill of Monte Carlo, for they contain no foreign plants, but a luxurious collection of indigenous flowers and shrubs. Nevertheless, all this may be seen in a couple of hours. The case is very different with regard to the Casino. Even those who do not play spend every day many hours within the walls of this magnificent building. The admission is absolutely free, and there are concerts twice a day, given by one of the best orchestras in Europe. The theatre, built by Garnier, the architect of the Paris Grand Opera, is in itself a sight which would attract thousands of people, even without the concerts and theatrical representations. Then there is a reading-room, with more than a hundred periodicals in all languages; and the Atrium, a magnificent hall, where people walk up and down for hours together, talking to their friends; the Atrium is, in fact, the universal rendezvous, where half the gossiping of Monte Carlo takes place.

These explanations are necessary to show that the sanitary condition of the Casino must have an important influence on the health of those persons who spend any time in the Principality. It so happens, however, that though money has been lavished on this superb building and no pains have been spared to render it attractive, the usual continental ignorance with regard to sanitary matters has very considerably marred the general result. The organisation of the drainage has been left to mere hazard, and the same may be said with respect to ventilation. There are eight closets for the use of the public in the basement of the Atrium, placed back to back and separated by a narrow passage. Formerly a small metallic pail or *tinette* was placed under each closet, which only retained the solid materials; and, incredible as it may seem, the liquid contents were actually allowed to overflow on the floor of the passage. The floor being slightly concave, the sewage, of a very offensive and concentrated description, slowly trickled to the centre, thus converting the passage into an open drain gravitating towards a little sewer. Of course, the smell from this passage occasionally invaded the whole building. This is now, however, altered. The *tinette* system is abolished. English closets, draining into hardware pipes, are employed in their stead. The flush is insufficient and badly delivered, but still the closets are free from odour, and the passage is no longer a standing nuisance. Here the improvements end. Immediately outside and almost touching the wall of the Casino

Digitized by Google

an immense cesspool has been constructed. As the law of the Principality forbids the draining of closets into the sewers, it may be thought that the building of a cesspool was unavoidable; but a special enactment was obtained from the Government exempting the Casino from this rule. Unfortunately the only use made of this advantage has caused more harm than good; for not only has the obnoxious cesspool system been maintained, but, availing themselves of their special privilege, the Casino authorities have allowed an overflow pipe to be added. Thus, after the accumulation of several cubic yards of sewage—that is to say, when the sewage has had plenty of time to ferment and to attain its foulest and most dangerous condition—it reaches the level of the overflow pipe and escapes into the sewers. Of course the smallest quantity of sewage in such a state gives rise to great nuisance, particularly as the sewers at Monte Carlo are not systematically flushed or ventilated. It is extraordinary that in the nineteenth century such obvious errors should be committed. The Casino is so close to the sea and the sewer outfall that, though the sewers are not properly constructed, no great harm would have arisen if the building drained direct into them, particularly, as with the new English closets, a considerable volume of water is now employed. But to allow the sewage to accumulate, to ferment, and then permit its slow but continuous flow into the sewers, is simply to poison the whole neighbourhood. Far from the Casino, and on higher ground, the sewer mouths have given off odours which have surprised persons not acquainted with these details. Evidently the cesspool must be abolished altogether, or else the overflow must be carefully closed and the cesspool periodically emptied, like all the other contrivances of this description within the Principality.

Apart from this, during the present season and for many weeks the most appalling odours have prevailed throughout the Casino, especially in the reading-room and in the theatre. One waterspout running outside a wall was discovered and pulled down. It communicated with the sewer, and, being in a leaky condition, enabled foul gases to travel upwards into the wall. A new pipe has been substituted, which is made to empty over an open gully, and thus the connexion with the sewer is effectively severed. This is one of the very rare instances of an improvement accomplished which is scientifically correct. But there are other defects that have not been discovered, and the constant escape of sewer-air within the Casino is all the more dangerous as the building itself is completely devoid of any system of ventilation. The air depends for its renewal on the hazard of opening doors or windows. There are a great number of "lanterns" on the roofs of the gaming-rooms, but these are so low that when opened a violent down-draught ensues. Consequently they are nearly always shut, and intolerable heat and closeness result. Undoubtedly the excitement of gambling is most injurious to the health; but when combined with the respiration of foul air, contaminated by the breath of thousands of people, by the emanations from badly-constructed drains, and the burning of hundreds of lights, the result is even more disastrous. As Monte Carlo is not only of itself one of the best health-resorts on the Riviera, but is easily and constantly visited by invalids from Cannes, Mentone, Nice, &c., these considerations are of great importance. The public have at least the right to expect that the wealthy owners of the Casino will try to provide pure air for the three or four hundred thousand visitors who each year are tempted to try their fortunes at the *roulette* or *trente et quarante* tables. In this case it is not so much a matter of expense as of knowledge. The directors of the Casino do not know what to do. They are not men of science, and the persons in their employ are men of art and men of business who have never had any opportunity of learning anything about sanitation. Thus more money has been spent in building what has proved to be the cause of nuisance and of danger to health than it would have cost to construct drains correctly laid, ventilated, trapped, and intercepted. But this excuse does not deprive the public of the right to protest; and, as yearly the climatic advantage of Monte Carlo as a health-resort is better appreciated, both by physicians and by patients, it becomes a duty to point out these defects. Moreover, there is every reason to feel the utmost confidence that the directors of the Casino would make considerable alterations if they were certain that the desired improvements could be secured. It would be difficult to find in all Europe a building where, during the course of the year, so great a number of people congregate and remain for so many hours within its walls. But this season many persons have been positively driven away by the bad smells; and, if for no higher motive, self-interest points to the necessity of better ventilation and better drainage. Enough has been done for outward show and outward attractions; care must now be taken that, in contemplating the fine paintings, decorations, and architectural beauties of the Casino, or in listening to its unrivalled orchestra, the visitor shall no longer be inconvenienced by impure air and insufficient ventilation. Indispensable improvements of this description, there is little reason to doubt, will be attempted at no distant date. The directors have discussed these matters on several occasions. Many projects have been submitted to them, and it is to be hoped that they will soon have succeeded in selecting a good working plan. In that event it will be a pleasure to notice favourably that which, at present, and in the public interest, it is necessary to criticise somewhat severely.

LIVERPOOL.

(*From our own Correspondent.*)

THE NORTHERN HOSPITAL AMBULANCE.

SOME idea of the great value of a well-organised ambulance service in such a city as this is shown in the account given of one day's work done by the ambulance of the Northern Hospital. On the 28th ult. there were removed to the hospital the following cases:—1. A sailor, suffering from scalp wounds, concussion of the brain, and compound fracture of the leg. 2. A carter, who had sustained a scalp wound and concussion of the brain. 3. A man, seventy-two years of age, with a fracture of the thigh. 4. A stableman, who had been thrown from a trap, and had sustained a scalp wound with concussion of the brain. A well-appointed horse ambulance must soon become a necessary adjunct to every large general hospital in town or country.

RECENT LOCAL HOSPITAL CHANGES.

Dr. Bradshaw has been elected Physician to the Stanley Hospital. Dr. Ellis, Hon. Assistant Physician to the Hospital for Women, has been elected Honorary Medical Officer for In-patients; and Drs. Bernstein and Crozier have been elected Honorary District Medical Officers to Districts 4 and 9 of the Ladies' Charity and Lying-in Hospital.

OVERCROWDING IN THE LIVERPOOL WORKHOUSE.

For some time past the Liverpool Workhouse, though of considerable dimensions, and probably one of the largest institutions of the kind in the kingdom, has been found to be inadequate to meet all the demands made upon it. When it is borne in mind that the greater part of the buildings were erected many years ago, this will not appear surprising. Steps are being taken to remedy the overcrowding which exists, but nothing can be done till after the report of the Local Government Board inspector.

PREVALENCE OF MEASLES.

At the meeting of the Health Committee on the 31st ult., the medical officer of health reported that there had been during the week 9 cases of fever, 31 of scarlatina, and 171 of measles. He regretted to say that the latter was on the increase; there had been 33 deaths from it since the previous week, representing 10 per cent. of the total deaths, while it was the largest number of deaths from measles in a single week that he had known for a great number of years. In one school in Toxteth Park there were no fewer than fifty children absent on account of it. The committee had no power to close the schools except with the consent of the managers, and there was no hospital accommodation whatever.

LIVERPOOL FOUNDLING HOSPITAL.

The first report of the Liverpool Foundling Hospital has recently been published. Its object is the double one of affording to women who have fallen *once only* an opportunity of regaining respectability, and of providing a home for the children of such women. Besides receiving infant children, the hospital contains wards for the confinement of unmarried women, *eligible under the rule of previous good behaviour*, who are thus enabled to return to a respectable life, leaving the child in the hospital. The institution has been at work for about nine months. Eight infants have been admitted; and two, whose mothers have since gone back into domestic service, have been born in the hospital.

DUBLIN.

(*From our own Correspondent.*)

THE QUEEN'S JUBILEE.

At a recent meeting of the Executive Committee of the City and County of Dublin Jubilee Committee, it was resolved unanimously that a hospital for consumption and diseases of the chest would be a memorial most likely to receive support from the public, the hospital to be in the county of Dublin. Various other suggestions had been started, but the foundation of a hospital for chest affections was considered the most desirable project in celebration of Her Majesty's Jubilee. Accordingly a meeting of the Celebration Committee was held last week, under the presidency of the High Sheriff of the county, and after some discussion the resolution above referred to was adopted by 23 to 14. It has been stated that Dublin is over-hospitalled, and that it would be better to utilise the money collected by establishing Jubilee wards in the present existing hospitals. There are, however, in my opinion, many and valid objections to this proposal, while, on the other hand, the erection of a special institution for chest affections at Killiney, a sheltered and salubrious locality on the coast about ten miles distant from the city, is one which may be expected to meet with much greater approval. General hospitals are not the places for consumptive patients, and in advanced stages of the malady not only are those institutions unsuitable to the patients, but they are a constant source of annoyance to the other inmates of the wards. It must also be remembered that these patients occupy beds which might with greater advantage be tenanted by sufferers from more curable maladies. This view of the matter has been adopted for some years by the authorities of the Belfast Royal Hospital; and, as a result, for some time before the foundation of the Hospital for Consumption,[1] patients in the advanced stages of the disease were refused admission into the wards of the only general hospital in that large and populous town. I do not intend to discuss the cost of the proposed institution, but shall merely refer now to the absolute necessity of such a hospital as is now proposed to be established. The Registrar-General for Ireland has pointed out that one-tenth of all the deaths in Ireland are caused by consumption, and one-sixth by diseases of the respiratory organs other than phthisis; while in Dublin the mortality is relatively higher. It is sincerely to be hoped that a substantial sum may be obtained for the erection and endowment of a hospital of the kind, which would be the most fitting Jubilee gift that could be offered by Her Majesty's loyal subjects in this country.

RICHMOND DISTRICT LUNATIC ASYLUM.

In last week's issue I referred to the insanitary condition of this asylum, and in consequence of the report of the resident medical superintendent the governors held a meeting last week, when it was determined to hold an inquiry into the defects to which attention had been directed. I am informed that Sir Charles Cameron, medical officer of health and city analyst for Dublin, and Mr. Wilkinson have been engaged to investigate the matter, and any suggestions made will at once be carried out.

NATIONAL EYE AND EAR INFIRMARY, DUBLIN.

In the Dispensary for Diseases of the Throat, which was established about three years since as an adjunct to the ear department, 124 new cases were treated during the past year, and of these a large proportion consisted of aural patients who were found to have throat complications. The hospital is certainly carried on with due regard to economy, for the sum paid in salaries during the year, including that of the house-surgeon, only amounted to something over £100.

THE MEATH HOSPITAL.

At the annual meeting held on Monday the committee acknowledged the very handsome bequest from the late Mr. John Barber, amounting to £4500, which it is intended to expend in erecting a memorial ward, to be called the "Barber Ward." Mr. O'Reilly Dease, D.L., has also given a sum of £200 for the necessary expense in tesselating the entrance hall and accident corridor, as the first part of a memorial to his father and grandfather, both gentlemen having been distinguished surgeons of the hospital.

I understand that, at last, the report of the Dublin Hospitals Commission has been placed in the hands of his Excellency the Lord-Lieutenant.

The death is reported at Gorey, from blood-poisoning, of Dr. George Weldon, in his sixty-first year.

Dublin, April 5th.

[1] Erected by the benevolence of a citizen, Mr. Forster Green.

Obituary.

JOHN BRADY, F.R.C.S.I.

ON the 27th ult., at Rugby, a gentleman remarkable in his generation passed from our midst. Born in the year 1813 in the county of Cavan, Ireland, Mr. Brady at an early age repaired to London to study medicine, and in due course, becoming qualified, he started in practice in the Borough, in partnership with his brother Charles, who enjoyed the reputation of being a very skilful and accomplished surgeon. Quickly they established a large and lucrative practice, which doubtless would have become even more extensive, but for the fact of the partnership being terminated in consequence of the subject of this notice retiring from practice shortly after his marriage, in 1847, with a wealthy heiress, Miss Pritchard, of Ely, by whom he had two daughters, who survive him. Mrs. Brady died in 1860, and Mr. Brady never married again. Possessed of a singularly active and cultivated mind, he could not content himself with a life of idleness, so, turning his attention to politics, he entered Parliament as member for Leitrim in the year 1852, which constituency he represented uninterruptedly for twenty-seven years, his connexion with it being closed in consequence of failing health. As characteristic of the man, it may be mentioned that on the occasion of his first contesting Leitrim he was strenuously opposed, in consequence of his liberal opinions (opinions which nowadays would be looked upon as being conservative), by the leading Conservatives of the county, but subsequent acquaintance with his integrity of purpose and independence of character converted many of them into his staunchest political adherents. Firmly impressed with Roman Catholic doctrines, he was to a very remarkable degree tolerant of the religious belief of those who differed from him; generous to a degree, charitable, hospitable, and warm-hearted, to know him was to love him. In the year 1869 he introduced into Parliament the measure with which his name should always be gratefully associated, and on August 2nd, in that year, the "Medical Officers Superannuation (Ireland) Bill" became law. The writer of this notice was in the House on the Wednesday upon which he moved the second reading of the Bill, and well recollects the impression which his judicious and able statement made upon a most attentive audience. In recognition of this and other professional services, the Royal College of Surgeons in Ireland, on August 5th, 1869, conferred upon him their Honorary Fellowship. Mr. Brady was, moreover, a highly educated man and a ripe Shakespearian scholar, to which circumstance possibly may be attributed the fact of his intimacy with all the leading actors of the day, by whom he was looked up to as an authority. In addition to his professional distinctions, Mr. Brady was a J.P. and D.L. for Cambridgeshire in England and for the county of Leitrim in Ireland.

THE MARGATE ROYAL SEA-BATHING INFIRMARY.—At the annual meeting of the governors of and subscribers to this institution on the 31st ult., it was reported that during the past year 636 patients had been treated in the infirmary, of which number 495 had been discharged, seven had died, and 137 remained in the hospital. The out-patients during the year had numbered 36. The pecuniary support afforded is lamentably insufficient, and the committee have had great difficulty in carrying on the work of the charity during the past year. Increased and additional subscriptions are earnestly appealed for by the directors.

THE annual general meeting in connexion with the Victoria Hospital for Sick Children, Hull, was held on the 4th inst., when satisfactory reports were presented and adopted.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners held on March 28th and following days, the under-named, having passed their final examinations for the Letters Testimonial, were admitted Licentiates of the College:—

Joseph Daly, Richard H. Dickson, John W. Haughton, Joseph Lavertine, Reginald Rygate.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on March 31st:—

Hebblethwaite, Harold, Grove-terrace, Bradford.
Lingwood, Edgar Henry, Corrance-road, Brixton.

A NEW hospital is shortly to be erected in Hull, to be called the Hull Orthopædic Hospital.

HOSPITAL SUNDAY collections were held at Hartlepool on the 3rd inst.

THE Duke of Northumberland has signified his intention to give a site, consisting of 3000 square yards, for the proposed new infirmary for the borough of Tynemouth. The ground is valued at £1200.

BEQUESTS.—The treasurers of the Oldham Infirmary, the Southport Infirmary, and the Southport Convalescent Home have each received cheques for £2700 from the executor of the late Mr. George Redford, of Southport.

THE BRITISH OPHTHALMIC HOSPITAL, JERUSALEM.—A meeting of the friends of the above institution was held at the Jerusalem Chambers, Westminster Abbey, on the 30th ult. Sir Charles Warren was in the chair.

AT the Loughborough Petty Sessions on the 30th ult., a butcher was fined £10 and costs, or, in default, one month's imprisonment, for exposing for sale sixty-seven pieces of unwholesome meat.

MEDICAL MAGISTRATE.—Joseph Todd, M.R.C.S. Eng., and L.S.A., of Selby, qualified on Monday, the 4th inst., at the Quarter Sessions, as a Magistrate for the West Riding of Yorkshire, having been placed on the Commission of the Peace in January last.

ON the 30th ult. a new underground reservoir, recently constructed by the Water-works Company, to contain half a million gallons of water, was inaugurated at Tonbridge by Lady Goldsmid. The town has now a good supply of excellent water.

WORCESTER INFIRMARY.—At the recent annual meeting of the governors of this institution it was reported that the income during the past year had amounted to £3647, and the expenditure to £4391. The number of in-patients amounted to 1288, and of out-patients to 5214.

PRESENTATION.—On the 31st ult., Dr. Murdoch Cameron was presented by the students attending the midwifery classes of the University of Glasgow with an address signed by all the members of the class, in acknowledgment of his services as their teacher during the absence of the professor, Dr. Leishman.

ROYAL COLLEGE OF SURGEONS IN IRELAND MEDICAL SCHOOL.—The following have been awarded prizes in Anatomy for the past session:—Descriptive Anatomy: Senior prizeman, Mr. McIlwaine, £3 3*s.*; junior medalist, Mr. Wright. Practical Anatomy: Senior prizeman, Mr. Warren, £3 3*s.*; junior prizeman, Mr. Wright.

BIRMINGHAM MEDICAL INSTITUTE.—The annual meeting in connexion with this institute was held on the 31st ult., Mr. J. V. Solomon, President, in the chair. From the report, which was presented and adopted, it appeared the number of members has been increased by 173 during the past five years, the number of books taken out by members had increased by 1176, and during the past year the number of borrowers was 138, as compared with 73 in 1881. Dr. James Johnson was elected president for the ensuing year; Messrs. Gilbert Barling and Wood White were re-elected honorary secretaries, and Dr. Saundby and Mr. Bennett May librarians.

AT a recent inquest held at Portsmouth, the jury returned a verdict that the deceased had died from blood-poisoning caused by eating tinned salmon which was unfit for food.

AT the usual monthly meeting of the members of the Association of Public Sanitary Inspectors on the 2nd inst., Dr. Alfred Carpenter delivered an address on "Theory and Practice as to Disinfection." A discussion, in which several of those present took part, followed the reading of the paper.

SANITATION IN JAPAN.—Mr. W. K. Burton, senior engineer to the London Sanitary Protection Association, has been appointed Professor of Sanitary Engineering to the Imperial Institute, Tokio, by the Government of Japan. This institution is, we believe, the only college in the world as yet where such a professorship exists.

VOLUNTEER MEDICAL STAFF CORPS.—The Secretary of State for War has approved of the formation of a Volunteer Bearer Company at Manchester. The total strength of the company will be 100. It is to be an independent unit, subordinate to the military and medical authorities of the district. The company's formation will date from April 1st, 1887.

NORTH-WEST LONDON HOSPITAL.—On the 1st inst. the general court of governors of this institution was held for the purpose of receiving the eighth annual report. It was stated that during 1886 602 in-patients had been admitted, and 33,687 cases treated as out-patients, 10,673 of these being new cases. The receipts for the year amounted to £3477, the annual subscriptions producing £536 of this sum.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for successful vaccination in their respective districts:—Mr. Edward Jay, St. George's, Hanover-square; Dr. G. Hales Parry, Docking Workhouse and District, Norfolk (third time); Mr. Thomas Brett Young, of the Romsley District of the Bromsgrove Union; Mr. F. W. Lewis, of Llandovery Union (second time in succession).

AT the monthly meeting of the Manchester Royal Infirmary Board, held on the 28th ult., Mr. Alderman King presiding, it was reported that an arrangement had been made for the reception of cases of infectious disease from Salford at the Monsall Hospital, in consequence of the infectious hospital at Cross Lane, Salford, having been purchased by the London and North-Western Railway Company for the purposes of railway extension.

ST. JOHN AMBULANCE ASSOCIATION.—A course of lectures on "First Aid to the Injured" has been recently delivered to some of the senior boys of King Edward VI.'s Grammar School, Berkhampstead, by R. L. Batterbury, M.D. Lond., one of the medical officers of the school. The examination was conducted by Surgeon-Major Casson, and, out of twenty-five candidates, twenty-three are reported to have passed, and will obtain the certificate of the Association.

UNIVERSITY COLLEGE HOSPITAL.—The annual meeting of the supporters of this institution was held on the 31st ult., when it was reported that 2638 patients had been admitted during the year, of which number 1260 were cured and 868 relieved. The out-patients numbered for the year a total of 35,765, besides which a large number had been seen on the recommendation of local and other medical men, making the total of in- and out-patients upwards of 40,000. The number of beds during 1886 was 209. A hope was expressed that this Jubilee year would see the debt of about £14,000 cleared off.

THE JUBILEE.—The amount contributed to the Jubilee Fund for the extension of the Aberdeen Infirmary now stands at £16,264. The sum required is £30,000. It has been decided to erect a Jubilee cottage hospital at Castle Cary.—About £420 has been promised to the building fund in connexion with the Dartmouth cottage hospital scheme, and £86 annual subscriptions; the total amount required, however, being about £2000.—On the 31st ult. a new infirmary and dispensary was opened in Bideford. The institution, which has cost about £2000, has been, in celebration of the Jubilee, opened free of debt.

Examined and found correct. CARTER & CARTER, Chartered Accountants, Birmingham.

MEDICAL NOTES IN PARLIAMENT.

Dublin Hospital Commission.

IN the House of Commons, on the 4th inst., Dr. Kenny asked the Chief Secretary to the Lord-Lieutenant of Ireland whether the report and minutes of evidence of the Dublin Hospital Commission were yet ready; if not, when members might expect them to be laid upon the table.—Mr. A. J. Balfour, in reply, said that it is understood that the report will shortly be submitted to the Lord-Lieutenant. On its receipt the Irish Government will be in a position to consider whether it, as also the minutes of evidence, should be laid upon the table.—Dr. Tanner asked an explanation of the delay.—Mr. A. J. Balfour presumed the delay had occurred in the writing of the report, but he reminded the hon. member that it by no means followed because a report was presented that it should therefore be laid on the table of the House. That was a matter within the discretion of the Lord-Lieutenant.

Indian Medical Staff.

On the 5th inst., in answer to Dr. Tanner, who asked as to the rank and allowances of officers belonging to the medical staff of India under six years' service, Sir J. Gorst stated that the rank of these officers is that of surgeon. Their allowances are more than those of subalterns, but less than those of captains. After six years they are more than those of captains. They do receive the allowances of their rank. There are no claims appertaining to relative rank and no less is suffered.

The Pharmacy Acts Amendment Bill.

On Tuesday morning, Dr. Farquharson moved the second reading of this Bill, briefly narrating the circumstances which led to its introduction, and urging that its enactment would be in the public interest.—Dr. Clark regretted that he felt it his duty to oppose the second reading. The object of the measure was to give additional powers to the Pharmaceutical Society, and powers which it ought not to possess. Up to 1868 anyone could carry on the business of a chemist and druggist, but in that year a Register of chemists and druggists was drawn up, and those who practised the trade were called upon to pass a qualifying examination. But now the Society wished to go still further, and to be allowed to create a curriculum, and to compel students to pass in chemistry, botany, and materia medica. The only result of the passing of the Bill would be to make the trade a close corporation, to make it easy for students to pass in large towns, but to make it almost impossible for those to qualify who lived in small towns and poor neighbourhoods. By allowing the Bill to pass the House would depart from the principle of free trade, by limiting the sale of drugs to a very small class, and he could only say that if this power was to be conferred on any body, it should be given to a public body, and not to a private society of traders, who could make bye-laws which should have all the effects of an Act of Parliament. If the Bill were pressed and carried to a second reading, he should feel it his duty in committee to endeavour to amend it and make the Pharmaceutical Society more representative of the 12,000 members of the trade. In his opinion there was no necessity for the proposed change, and he should therefore move that the Bill be read that day six months.—Mr. H. J. Wilson seconded this amendment.—Mr. Chance supported the Bill on the ground that it would assimilate English and Scotch law to that prevailing in Ireland, which had worked so satisfactorily.—Dr. Tanner thought there was considerable fear that the rights of many chemists and druggists were not properly respected. He urged that the second reading should be deferred a few days to allow some necessary amendments to be drafted. On a division the Bill was read a second time by 76 votes to 22.

The Committee stage of this measure came on for consideration on Wednesday morning at 2 A.M. On the motion that the Deputy Speaker do now leave the chair, Colonel Hodge moved the adjournment of the debate. The Bill had passed through the second reading with only a slight run of opposition, and he hoped the House would agree to an adjournment.—Dr. Farquharson said he had himself intended to move the adjournment of the debate, and subsequently to move to report progress. Many members were deeply interested in the Bill and desired to put amendments on the paper, and to have longer time for its consideration.—Mr. Chance and Mr. Lowther supported the motion for the adjournment.—Dr. Tanner said there were several points in the Bill which demanded investigation. It was alleged at first that the Bill was the same as the law which applies to chemists in Ireland. Accordingly from what he knew of the measure, he was not at all satisfied about it, and he should certainly support the adjournment.—Dr. Clark said he thought his hon. friend the member for Aberdeenshire might accept the motion. The Bill was brought forward between two and three o'clock on the previous evening and advanced a stage. It was an important measure, affecting thousands of people whose livelihood would be taken away.—Mr. Biggar also supported the motion for the adjournment, which was carried by 95 votes against 29. The debate was accordingly adjourned till Tuesday, April 19th.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ABBOTT, C. E., M.R.C.S., L.K.Q.C.P.I., has been reappointed Medical Officer of Health for the Braintree Rural Sanitary District.

BERNSTEIN, MEYER J., M.B., C.M.Ed., has been appointed Honorary Medical Officer for the Fourth District of the Liverpool Ladies' Charity and Lying-in Hospital.

CAPE, JOSEPH THOMAS, M.R.C.S., L.S.A., has been re-elected Medical Officer of Health by the Rural Sanitary Authority of the Totnes Union.

CHICK-LUCAS, J. R. G., M.R.C.S., L.S.A., has been appointed Honorary Medical Officer to the Ryde Dispensary, Isle of Wight.

CROZIER, WILLIAM, M.K.Q.C.P.I., L.R.C.S.I., has been appointed Honorary Medical Officer for the Ninth District of the Liverpool Ladies' Charity and Lying-in Hospital.

DOWDING, ALEX. W. WOODMAN, M.D.Durh., M.R.C.S., has been appointed Medical Officer for the Haughley District of the Stow Union, vice Stephens.

DURWARD, JAMES STEWART, L.D.S. R.C.S.Ed., has been elected to the Senior Staff of the Edinburgh Dental Hospital.

EDIS, JOHN BUTLER, M.R.C.S., L.R.C.P.Ed., has been appointed Hon. Surgeon to the Hospital for Women, Shaw-street, Liverpool.

EUSTACE, MARCUS, B.A., M.B., B.Ch.Dub., has been appointed Medical Officer for the Second District of the Alresford Union.

FALKINER, NINIAN MCINTIRE, A.B., M.B., B.Ch.Dub., has been appointed Visiting Physician to the Convalescent Home, Stillorgan, Dublin.

FLETCHER, RORY, M.R.C.S., L.S.A., has been appointed Resident Medical Officer to the Male Lock Hospital, Dean-street, Soho, W., vice G. W. H. French, F.R.C.S.

GOODALL, JOHN KENAT, L.R.C.S., L.R.C.P.Ed., has been reappointed Medical Officer for the Bolsover District of the Chesterfield Union.

HAGYARD, ROBERT, M.R.C.S., L.S.A., has been appointed Honorary Surgeon to the Hull Orthopædic Hospital.

HALL, ANDREW JOHNSTON, M.A., M.D., C.M.Glas., has been appointed Medical Officer for the Parish of Rothesay, vice Maddever, deceased.

HASWELL, J. F., M.B., C.M.Edin., has been appointed Junior House-Surgeon to the Northern Hospital, Liverpool, vice C. C. Charlton, resigned.

HUNTER, CHARLES BUCHANAN, M.B., C.M., has been appointed Surgeon to H. H. the Nizam's Railway, Hyderabad, India.

HUTCHESON, JAMES, M.B., C.M.Ed., M.R.C.S., L.R.C.P.Lond., has been appointed Surgeon to the Edinburgh Royal Maternity and Simpson Memorial Hospital.

JOHNSTONE, WM., has been appointed Public Analyst to the Boroughs of Dartmouth and Dunstable.

MACKENZIE, THOMAS, M.A.Glas., M.B., C.M.Ed., has been appointed House-Surgeon to the Edinburgh Royal Maternity and Simpson Memorial Hospital.

MARTIN, MATTHEW, M.B., C.M.Glas., has been appointed Medical and Surgical Officer to the Parkhead Steel and Rolling Mills, Glasgow.

OWEN, RICHARD JEFFERYS, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Second District of the Llandovery Union.

PACKER, W. HERBERT, M.D., L.R.C.P., has been appointed Medical Visitor to the Shropshire Private Lunatic Asylums, vice Edwyn Andrew, M.D., deceased.

ROBERTS, JAMES B., M.B., C.M.Ed., has been appointed Medical Officer for the Fourth District of the Nottingham Union.

SEMPLE, HENRY F., M.R.C.S., L.R.C.P., has been appointed House-Surgeon to the Bristol Hospital for Sick Children and Women, vice E. Leonard Lees, M.B., C.M., M.R.C.S.

STADDON, WALTER JOSEPH, M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Medical Officer for the Workhouse of the Leeds Union.

WARE, GEORGE STEPHEN, M.R.C.S., L.R.C.P., L.S.A., late House-Physician and Obstetric House-Physician, has been appointed House-Surgeon to the Middlesex Hospital.

WILSON, JAMES, M.B., C.M.Glas., has been appointed Surgeon to the Bethlehem Lodge of Ancient Shepherds, vice A. Muir Smith, resigned.

WILSON, WILLIAM, M.B., C.M.Ed., L.R.C.S., L.D.S., has been elected to the Junior Staff of the Edinburgh Dental Hospital.

YEATMAN, J. W., M.R.C.S., has been appointed Government Medical Officer for the Upper Wakefield and Saddleworth Districts, South Australia, vice H. F. Harvey, M.R.C.S., resigned.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Resident Clinical Assistant. A gratuity of £20 is usually awarded at the close of the term of office (six months).

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, N.—Aural Surgeon.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, W.C.—Clinical Assistants in the Out-patient Department.

QUEEN'S HOSPITAL, Birmingham.—Obstetric and Ophthalmic House-Surgeon. The appointment carries with it board, lodging, &c.

Digitized by Google

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, Ventnor.—Assistant Resident Medical Officer. Small honorarium.

SCARBOROUGH FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Resident Medical Officer. Salary £300 for the first year, £220 for the second (if satisfactory), with fees extra, and residence, free of rates and taxes, with an allowance for coals and gas.

SMEDLEY'S HYDROPATHIC ESTABLISHMENT, Matlock-bridge, Derbyshire.—Junior Resident Physician. Salary £150 per annum for the first year, with accommodation in the establishment.

ST. PANCRAS INFIRMARY, Dartmouth-park-hill, Highgate, N.W.—Dispenser. Salary £100 per annum, with dinner daily, and, subject to the approval of the Local Government Board, rising by £10 annually, to £120.

Births, Marriages, and Deaths.

BIRTHS.

BLOXAM.—On the 31st ult., at George-street, Hanover-square, W., the wife of J. Astley Bloxam, F.R.C.S., of a son.

BOWES.—On the 2nd inst., the wife of John Ireland Bowes, Medical Superintendent of the Wilts County Asylum, Devizes, of a daughter.

EAST.—On the 30th ult., at Upper Berkeley-street, Portman-square, W., the wife of Edward East, M.R.C.S., of a son.

MORRIS.—On the 29th ult., at Windhill, Bishops Stortford, Herts, the wife of John Edward Morris, M.D., of a son.

O'CONNELL.—On the 29th ult., at North-villas, Havelock-park, Southsea, the wife of Surgeon-Major R. O'Connell, of a daughter.

RUSHBROOK.—On the 3rd inst., at Upper Phillimore-place, Kensington, Janet Monteath Rushbrook, L.K.Q.C.P.I., L.M., wife of Henry George Rushbrook, of a daughter.

SHAW.—On the 17th ult. (St. Patrick's day), at Mildenhall, Soham, Suffolk, the wife of H. C. Costello Shaw, L.R.C.P.Lond., M.R.C.S., of a daughter.

TROTT.—On the 13th ult., at Waterloo, Hamilton, Bermuda, the wife of Dudley C. Trott, M.B., B.C., F.R.C.S., of a daughter.

MARRIAGES.

CRANE—CRANE.—On the 2nd inst., at the Parish Church of St. Marylebone, Leonard Crane, M.D., Surgeon-General, Trinidad, to Lillie, fourth daughter of the late Wm. Crane, Speaker of the House of Assembly, New Brunswick.

JONES—JONES.—On the 30th ult., at St. George's Parish Church, Beckenham, Kent, John Hills Jones, M.B., C.M., to Catherine (Kate), youngest daughter of the late Robert Jones, of The Mount, Llanfair, Montgomeryshire.

THOMSON—MACPHAIL.—On the 30th ult., at Free Church Manse, Kilmuir, Skye, N.B., John Thomson, M.B., C.M.Edin., to Isabel Finlayson, fourth daughter of the Rev. John S. Macphail, of Kilmuir.

DEATHS.

COATES.—On the 26th ult., at 1, Westbourne-street, Eaton-square, S.W., Frederick Thomas Coates, M.R.C.S.E., second son of the late George Coates, Surgeon, of Bloomsbury, aged 43. Deeply lamented.

HENSLEY.—On the 4th inst., at Coleherne-road, S.W., Frederick John Hensley, M.D., M.R.C.S., L.S.A., in his 65th year.

KEDDLE.—On the 29th ult., at The Elms, Beaminster, after a long and trying illness, Samuel Shering Keddle, M.D., J.P. for co. Dorset, within two months of completing his 90th year.

SHAW.—On the 31st ult., at Bishopsgate-street Without, after a lingering illness, Henry Shaw, M.R.C.S., in his 74th year.

STIRLING.—On the 30th ult., at Marine-parade, Brighton, Wm. Boughton Stirling, M.D., and of Nottingham-place, W.

VACHER.—On the 30th ult., at 31, Shrewsbury-road, Birkenhead, John, infant son of Francis Vacher, F.R.C.S.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE LITERATURE OF THE SPLEEN.

J. W. (Leicester).—The treatise referred to is by Dr. Guido Baccelli, President of the Accademia Medica di Roma, and some time Professor of Clinical Medicine at the Sapienza. It was published in Latin in the year 1876, and its title is "De Primitivo Splenis Carcinomate (histologice, lympho-sarcomate); historia, diagnosis, extispicium" (on Primary Carcinoma of the Spleen—in histological classification "lympho-sarcoma"—a history, diagnosis, and necropsy). It is inscribed in an appropriate dedication to Dr. Eduard Rindfleisch.

Alpha is thanked for his letter on the Leicester Sick Benefit Society. We shall be glad for any published statement of the case. We could not insert an anonymous letter.

M.B.—The matter should be brought under the notice of the Apothecaries' Society.

Alsina.—The name mentioned was not struck off the Register.

THE LUNACY BILL.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me through your columns to invite all workhouse medical officers interested in the Lunacy Acts Amendment Bill to attend our council meeting on Thursday, April 14th (5 P.M.), at 3, Bolt-court, Fleet-street, as the clause particularly affecting them will be under discussion. I am, Sirs, yours truly,

J. WICKHAM BARNES.

Poor-Law Medical Officers' Association, 3, Bolt-court, Fleet-street, E.C., April 4th, 1887.

Felix.—Dr. Frederick Roberts' book "Notes on Materia Medica" (Lewis) or Dr. Mitchell Bruce's Materia Medica and Therapeutics (Cassell) will give the proportions.

Mr. C. S. Jeaffreson.—The paper will appear shortly.

BREAD-MAKING.

To the Editors of THE LANCET.

SIRS,—In answer to the letter of Mr. Robert Jones in THE LANCET of the 26th ult., I beg to say that my late father, Dr. Thos. Smith, wrote an article entitled "An Improved and more Wholesome Mode of Making Bread." The article appeared in the *Leeds Mercury* of Feb. 17th, 1844, and I have a printed copy of the same.

I am, Sirs, yours truly,

Cheltenham, April 4th, 1887. FRED. A. A. SMITH, M.D.

THE FIFTY-TWO YEARS' PLAGUE.

ACCORDING to Procopius, "the Byzantine Herodotus," the Plague began A.D. 542 in the Nile delta at Pelusium, and dividing its forces it attacked Alexandra and the rest of Egypt on the one hand and Palestine on the other. Beginning always on the sea-shore, it penetrated inland, depopulating islands, caverns, hill tracts—wherever, in short, human beings were found. In its second year it invaded Byzantium in the middle of spring. Many of its victims felt themselves struck in some part of the body, when, by way of exorcising the assailant, they would utter some sacred word and hurry into the nearest temple. To escape the importunities of friends, others, again, would barricade themselves in their rooms and plug their ears so as not to hear the loud knocking at their doors. A feverish malaise arousing them from sleep or arresting them in their walk or at their work was the first symptom; but there was no change of colour, or sense of burning heat, or inflammatory affection, so that in the evening neither patient nor physician was alive to any danger. But many on the same day or the day following, or a considerable time thereafter, saw a bubo rising on the groin, or in the armpits, or on the parotids, or in other regions, and this symptom was common to every sufferer from the disease. Somnolence, stupor, or acute delirium were often present, with forgetfulness of every call of nature, so that many who happened to be without attendants died of hunger. Contact with patients or with the dead gave the malady neither to physician nor to sexton, while many—they knew not why or how—were attacked and succumbed in a few hours. Patients flung themselves into the sea or from high places in anticipation of death, while in others the bubo, not preceded by visions or delirium, passed into gangrene, and they died in convulsive agony. The physicians suspecting these plague ulcers to contain a poison which caused the disease, opened them in many dead subjects, and found them to contain a large carbuncle. Those cases in which the body was covered with black pustules, the size of a lentil, died within twenty-four hours, while others vomited blood till death relieved them. Errors in prognosis were infinite, able physicians foreseeing death where marvellous recovery supervened, and predicting recovery just before fatal collapse. Therapeutics were equally at fault. The bath was of use in some cases; worse than useless in others. It was quite as ineffectual to fly from the disease as to treat it—such was the ignorance as to its origin or its issue. Those in whom the bubos proceeded to copious suppuration got well, as with the defervescence of the carbuncle the signs of returning health revealed themselves. Recovery was not always, however, complete, the survivors being often afflicted with semi-paralysis of the tongue, impairing distinctness of articulation for life. In Byzantium the plague lasted four months, during three of which it was at its maximum, when the mortality reached 10,000 daily, till the city seemed deserted. Other details confirmatory, with few exceptions, of the powerful description by Procopius fill in the sombre picture, and must be drawn from the histories of Agathias and Evagrius. Gibbon, in his condensation, followed with greater authority by De Renzi, contests the dictum of Procopius that the disease was non-contagious, an epithet scarcely applicable to a visitation which passed from country to country, beginning at the seaports and penetrating inland. Another point indicated by De Renzi is the evidence deducible from Procopius that the Byzantine physicians practised morbid anatomy and sought out the causes of disease by pathological research:—"Even the Christians of the sixth century did not hold the dead subject to be so intangible as not to afford to science the means of exploring the structure of the body, and so of aiding anatomy" ("Scuola Salernitana," vol. i., p. 31).

Mr. Kingzett.—A specimen of the preparation should be sent for examination.

A One-eyed Engine-driver.—We cannot say we are greatly impressed with the force of the argument used by our correspondent.

A WARNING.

To the Editors of THE LANCET.

SIRS,—As a hint to my professional brethren, I send a line to say that a man called at my house yesterday afternoon, at about 3 o'clock, and asked if I was in. On my servant replying in the negative, he asked when I was expected, and was told that I would return in about half an hour. He said he would wait, and taking up a newspaper sat down In a very short time he was seen by my servant going out of the house, saying that he had some business to transact, and would call again. It is needless to say that he did not return, and it was discovered that he had taken with him a pocket dressing-case and binaural stethoscope, together of the value of from £4 to £5. The man was of middle height, dark complexion, about forty years of age, and called himself "Mr. Kerr."

I am, Sirs, yours faithfully,

ARTHUR H. T. LONGHURST, M.D.

Wilton-street, S.W., March 29th, 1887.

WINTER HEALTH RESORTS AT HOME.

A CORRESPONDENT is anxious to direct attention to the advantages of Colwyn Bay, North Wales, as a winter health resort for poitrinaires. "I have travelled," says the writer, "in many places in Europe and Asia Minor, but find no climate better than this." He regards the relief he has experienced from many severe symptoms of chest affection as due to the ameliorating influence of the climatic conditions prevailing in the four successive winters he has spent in the locality in question.

Mr. A. W. Stirling.—The note was founded upon an article in one of the March numbers of the *Lyon Médical* (March 13th?).

Mr. C. Roberts.—Next week.

RAPID STAINING OF THE TUBERCLE BACILLUS.

To the Editors of THE LANCET.

SIRS,—I can strongly recommend the following mode of staining the tubercle bacillus in cover-glass preparations for clinical purposes. It is a slight modification of Neelsen's method. The stain—which in my opinion is preferable to any of those containing solutions of aniline—is made by dissolving one part of magenta in 100 of a 5 per cent. watery solution of carbolic acid, and adding 10 of absolute alcohol. A sufficiency of this fluid is poured into a watch-glass, and heated on a retort-stand over a spirit lamp till steam rises freely and the temperature is not very far from the boiling point. The cover-glasses, prepared in the usual way, are then floated in the stain for two minutes; if the right temperature has been reached this is quite long enough; the watch-glass should be covered. In Neelsen's method the preparations are then decolourised with acid, and subsequently stained with blue as a contrast. I find that these processes may be very conveniently combined. By dissolving methylene blue in 25 per cent. sulphuric acid till a deep colour is obtained, and immersing the cover-glasses for one minute in this immediately after their removal from the magenta. They are then rinsed in water, dried, and mounted in balsam. The whole process of staining and mounting occupies about six minutes according to my experience. Possibly this method may have been already suggested; if so, it has escaped my notice.

I am, Sirs, yours faithfully,

Eastbourne, March 31st, 1887. HENRY S. GABBETT, M.D.

H. L. H.—1. On the 1st of June.—2. Spottiswoode's, East Harding-st., London, E.C.

Dr. Uhlworm (Cassel).—We cannot exchange.

THE SELFISH PRINCIPLE AND MEDICAL ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—Many of those who recognise the truth of M.D.'s letter under the above heading, in your last issue, will coincide with your comment upon it. We all know the Pharisee in medical etiquette; we know his ways, even if we cannot always escape his toils. These people should concern us very little. Luther is reported to have fought the great battle of the Reformation under the motto, "In quietness and confidence shall be your strength." Such also should be our motto, and it is not that of the complaining Pharisee. What "M.D." really means is that we general practitioners, who endeavour to bear our wrongs in silence, do not receive sufficient support from the medical papers. All that the Pharisee wants is recognition—an incomplete sympathy with his grievance suits him best, and his own glib tongue supplies what is lacking. These wasps of the profession cannot make honey, but they can use their stings, and they dip them in any available venom. The life work of every successful practitioner contains a ready antidote in his consciousness of good done, and perhaps less frequently in its grateful recognition. But no great good is attained without personal peril. Therefore, my brother "M.D.," take courage and persevere—as your work is, so shall your strength be; as your strength is, so should be your silence.

I am, Sirs, yours truly,

April, 1887. ANOTHER M.D.

G. M.—The subject is, we fear, hardly ripe for discussion, but will not be lost sight of.

A very old Subscriber has not enclosed his card.

WHAT IS BRONCHITIS?

To the Editors of THE LANCET.

SIRS,—Will you permit me through the medium of your valuable journal to ask the medical profession what is bronchitis? Is it a fever, and to be classified with other specific fevers, such as whooping-cough and measles? My own impression is that it is not, but that it is a diseased state of the bronchial tubes, invariably the result of fever poison, such as in influenza, (by far the most common cause), and also of typhoid, typhus, small-pox, measles, or some other fever poison. I think this is a matter which should be well thought out by the profession, or at the onset of a disease we may by the bronchitis be led away from the cause of the mischief. And in treating it we should put to ourselves the question, What is the cause of this derangement? Is it from within—i.e., from gout, or from without, from one of the specific fevers? I hold the same view with regard to pneumonia, pleurisy, and peritonitis.

I am, Sirs, your obedient servant,

Slough, April 4th, 1887. WM. U. BURKE, M.R.C.S.

ENGLISH PRACTITIONERS IN ITALY.

HOLDERS of British diplomas in Italy may practise among the English-speaking communities there without an Italian qualification. In Rome (which, as the capital, may be presumed to regulate the usage of the provincial towns) the English practitioner must, if called upon, be prepared to certify to the municipality his professional credentials by producing his diploma, or (still better) the British Medical Register containing his name. The Italian Government, indeed, so far recognises his right to practise in the Peninsula as to make him pay income-tax (*ricchezza mobile*) on the average of his professional income. An Italian qualification, however, is required if the English practitioner's *clientèle* extends to the native population, though cases are quite common in which Italian patients call in the English consultant possessing only a British qualification and remunerate him with a *honorarium* on the English scale.

R. P. (New York).—A dictionary of medical nomenclature cannot be called complete unless it gives correctly the pronunciation of each term. Angina, in the common collocation "angina pectoris," is usually mispronounced. The penult is short, as in the hexameter of Lucilius: "Insperato abiit quem una angina sustulit hora" (He departed unexpectedly, whom angina removed in an hour). Again, in the medical poem of Serenus Sammonicus: "Anginæ verò sibi mixtum sale poscit acetum" (But angina requires vinegar mingled with salt). It is also short in the "Trinummus" of Plautus, v. 540, ed. Cocchia (Turin, 1886), who rightly derives it from the Greek ἀγχόνη.

Justice.—If all the circumstances of the case are correctly stated by our correspondent, we have no doubt that an appeal to the head of the Department would ensure a reconsideration of, and a just decision upon, the claims of the officer concerned.

M.R.C.S.Eng.—From the description given of the lad, we should think the possession of the power attributed to him can scarcely be doubted.

ANOSMIA.

To the Editors of THE LANCET.

SIRS,—In response to "Constant Reader," I beg to suggest the following, and have no doubt if carried out relief will be experienced. Strychnine hypodermically injected at the sides of the nose, together with electricity (a battery of about thirty or forty cells), would best meet the requirements, which should be used daily. This would restore the sense of smelling if anything would, as the olfactory and other nerves would be directly roused by the above. Headaches would be best treated by bromide of potassium and belladonna, to which might be added small doses of tincture of nux vomica, and should be continued with steadily for some time. The solution of extract of ergot and tincture of hyoscyamus are often found of the greatest benefit in the treatment of headaches, and are worthy of a trial. Mild aperients would be essential, especially if any costiveness were present. Further, I should suggest the head to be bathed in cold water daily, and cold applications might be applied during attacks with advantage. The offensive odour is most probably due to some diseased teeth; thus a visit to a dentist would be desirable. A Turkish bath taken occasionally would be highly beneficial. Trusting that the above may be of some help,

I am, Sirs, yours truly.

March 30th, 1887. T. J. LAVERS, M.D., &c.

THE INTERNATIONAL MEDICAL CONGRESS.

To the Editors of THE LANCET.

SIRS,—I take the liberty of addressing you for the purpose of making a suggestion about the forthcoming International Medical Congress in Washington. If I remember aright, when the British Association met at Montreal a few years since the Canadian and American railways gave free passes over their lines to all members who had come from Europe. I think that if the American railway companies could be induced to grant a similar privilege to foreign medical men attending the Congress in September it would result in largely increasing the attendance, and would be an immense boon to many doctors of limited means, who otherwise would be debarred from visiting America. From what I know of the large-minded generosity of the American people, I am sure that if the matter were once laid before the directors of the principal American lines they would accede to the request without hesitation.

I am, Sirs, your obedient servant,

April, 1887. M.B.

Mr. T. Nixon.—Information may be obtained at the office of the Crown Agents for the Colonies, Downing-street.

CLIMATE OF RED BLUFF, CALIFORNIA.

To the Editors of THE LANCET.

SIRS,—I should be obliged could you or any of your readers give me some information concerning the climate of Red Bluff, California (lat. 40° N., long. 122° W.), especially as to its suitability to a patient with delicate chest and tendency to fibroid phthisis.

I am, Sirs, yours faithfully,

April 2nd, 1887. F.R.C.S.E.

ABSTRACT OF

Lumleian Lectures

ON THE PATHOLOGY OF INTRA-UTERINE DEATH.

Delivered at the Royal College of Physicians of London, March, 1887,

BY W. O. PRIESTLEY, M.D., F.R.C.P., LL.D.,

CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL, AND LATE PROFESSOR OF OBSTETRIC MEDICINE, KING'S COLLEGE.

LECTURE I.

CALLING attention to the importance of the subject which he had chosen for these lectures, not only in its general aspects and from a statesman's point of view, as influencing the law of population, but in its interest for the pathologist and medical practitioner, Dr. Priestley said that owing to the large extent of ground covered by it he must content himself with giving in outline a sketch of its broader dimensions, while he dwelt with greater detail on those sections which had more especially excited his interest, or in which he had personally made some investigation. The complex and intricate anatomical structure, and the alterations associated with the rapid development of the contents of the gravid uterus even in the normal state, render, the lecturer remarked, all investigation very difficult. When pregnancy pursues its natural course and development follows its normal progress, the changes which take place are incessant and varying. From the time at which the decidua is first formed in the interior of the uterus, to become the outermost of the fœtal membranes, to the formation of the fully-grown placenta, there is no pause or cessation in the active changes which characterise the progress of growth. The cells and fibres which build up the tissues day by day undergo progressive change, and the vessels equally undergo modification in size, form, character, and in their relation to surrounding parts. So, too, if any derangement occurs, either from accident or disease, the morbid change thus initiated is, or may be, impressed with the same activity of growth, rapid degeneration or abnormalities being produced with surprising quickness. Hence pathological researches into these unstable and ever-changing structures are beset with difficulties, and to this must be attributed the widely different views held by equally conscientious and accurate observers concerning the nature of some of the pathological results.

Many of the causes which either remotely or directly bring about intra-uterine death are very difficult to trace, and some are so subtle in their influence as to be impossible to detect. Thus the child dies in utero with some women in successive pregnancies and without any clearly assignable cause; it is not infrequent to hear of women apparently healthy aborting or losing their children in the later months of gestation ten, twelve, or thirteen successive times. Some women are so prone to miscarriage at any period of gestation, that the slightest imprudence seems to be enough to endanger the existence of pregnancy and to lead to a detachment of the ovum. This is in marked contrast to other and apparently not healthier women, who will bear an extraordinary amount of violence or injury without disturbance to pregnancy, in proof of which Dr. Priestley cited several instances from the experiences of Mauriceau, Henry Davies, Dupuytren, Laujardière, and himself. Whitehead's tables, taken from the records of the Manchester Lying-in Hospital, show approximately the frequency of embryonic death in the earlier stages of gestation, but do not accurately represent the frequency of abortion throughout the whole childbearing period, and a considerable proportion of the women included in them were pregnant for the first time. Dr. Priestley had recently drawn up tables containing the figures of some 400 private patients in whom the evidence of pregnancy having occurred was distinct and unequivocal. The results were as follows: 400 women had been pregnant 2325 times. Of these, pregnancy had resulted in living children 1783 times; and there had been 542 abortions. The proportion of abortions to children was therefore 30·40 per cent., or about 1 in 3; while the proportion of abortions to pregnancies was 23·32, or about 1 in 4. The number of women who had borne children but had never suffered abortion was 152 in the 400, or 38 per cent.; while the number of women who had borne no living child and only had abortions was 27, or 6·75 per cent.—the sum of the pregnancies in 400 women being therefore 2325, or 5·81 for each, and the sum of the abortions being 542, it was 1·35 for each.

TABLE I.—*Analysis of number of Women who had and had not Aborted.*

—	Women below 30 years of age (Whitehead).		Women over 40 years of age (Priestley).	
	No.	Per cent. of whole.	No.	Per cent. of whole.
Women who had not aborted ...	1253	62·65	152	38·00
Women who had aborted	747	37·35	248	62·00
Total number of women under observation	2000	100·00	400	100·00
Women who only aborted—that is, who had borne no living child	—	—	27	6·75

Table I. illustrates the point that whereas among the younger women the proportion who aborted was about one in three—that is, one aborted to two who did not—among the older women the proportion was almost exactly reversed, and two aborted to one who did not.

TABLE II.—*Analysis of Pregnancies in reference to Abortions and to Fecundity.*

—	2000 Women below 30 years of age (Whitehead).			400 Women over 40 years of age (Priestley).		
	No.	Per cent. of whole.	No. per woman	No.	Per cent. of whole.	No per woman.
Children	7459	85·92	3·73	1783	76·68	4·46
Abortions	1222	14·08	0·61	542	23·32	1·35
Total pregnancies ...	8681	100·00	4·34	2325	100·00	5·81

Table II. shows that the older period is more productive of pregnancies than the younger in the proportion of 5·81 to 4·34 (or four to three), but that the percentage of them terminating in abortions is also much greater in the older period than in the younger (23·32 against 14·08). Table III. illustrates the last point in another manner.

TABLE III.—*Ratio of Abortions to Pregnancies and Children.*

—	Whitehead.		Priestley.	
	Per cent.	Being about 1 in	Per cent.	Being about 1 in
Ratio of abortions to pregnancies	14·08	7	23·32	4½
Ratio of abortions to children ...	16·39	6	30·40	3½

It will be seen that the proportion of abortions to full-time pregnancies is considerably higher than Hegar's computation, which is about 1 abortion to every 6 or 10 full-time deliveries. The proportion approximates more closely to Dr. Whitehead's figures, but these is a larger average of abortions as the calculation embraces a longer portion of the reproductive period; and there is another notable difference, which may, perhaps, be put down to easier circumstances and exemption from bodily toil—namely, that if a comparison is made with Dr. Whitehead's limited data concerning those women who had passed the menstrual epoch, it will be remarked that while among the poor of the manufacturing town as many as 37 per cent. had incurred abortion, only 62 per cent. of the women in better circumstances had suffered in this way.

As to the particular pregnancies in which abortion most

Digitized by Google

frequently takes place considerable difference of opinion exists, and Dr. Priestley regards the computations on the subject made by Tyler Smith, Whitehead, and Schroeder as not at all satisfactory or conclusive, inasmuch as various elements—age, social position, the occurrence or not of a long journey immediately after marriage &c.—are not considered, and these elements are important factors in making the calculation, more particularly with reference to abortion in the earlier periods of pregnancy.

The relative period of utero-gestation in which intra-uterine death most frequently takes place has been variously stated, and for certain reasons cannot be very precisely determined. It is probably very frequent in the form of abortion during the early weeks of pregnancy, and then it may produce so little disturbance in a woman's health as to be scarcely noticed. Among the poor this is certainly the case, and consequently an estimate of its frequency among them is practically impossible. Madame la Chapelle regarded it as most frequent in the sixth month of utero-gestation. Cazeaux believes abortion to be most frequent in the first two or three months, and Depaul states its greatest frequency to be between two months and a half and three months and a half. Jacquemier, on the other hand, declares abortion is not less frequent in the sixth month than in the first half of pregnancy. Whitehead's figures show that of 602 cases of abortion, 275 occurred between two months and a half and three months and a half, and 147 between three months and a half and four months and a half.

The stage at which development has arrived—about three months to three and a half—points to a period when, *pro tanto*, abortion may be supposed to be the more readily brought about, which coincides with Whitehead's statistics. Then the villi of the chorion have become more concentrated on the decidua serotina, and the young placenta is in progress of formation. There is great increased vascular activity in all the tissues, and yet a certain instability, for the vascular loops projected from the maternal circulation are beginning to surround the fœtal villi in a delicate sort of network, and the spaces which intervene between the membranes, so obvious in the earliest weeks, are not yet obliterated. Besides, the union between the membranes and the uterine walls is less stable than later on, and so separation more readily occurs. Hence a greater liability to blood extravasations, not only into the layers of the decidua, but also between the several membranes, and more especially between the decidua reflexa and the chorion. From the twelfth to the sixteenth week the phenomenon of "quickening" occurs, and if anything hinders or prevents the ascent of the uterus into the abdomen abortion is precipitated. Morgagni and Desormeaux are of opinion that abortion is more frequent with female than with male embryos, but give no statistics; and Cazeaux's reason for thinking this may be true is scarcely a sound one—namely, because at term there are sixteen boys born to every fifteen girls.

In discussing the causes of intra-uterine death, classifications of which have been made by Spiegelberg, Leopold, Barnes, and others, Dr. Priestley announced his intention of taking first the causes acting through the male parent; then those which act through the intervention of the mother; and, lastly, those which more particularly belong to the fœtus itself, although possibly remotely related to both parents.

1. *Causes of intra-uterine death referable to the father.*—As the pollen-cells of a plant are sometimes imperfectly developed as the result of an unhealthy state of the plant, or as the pollen may be injured or spoilt before or during the time it is applied to the pistil, and the result be an imperfectly formed seed or fruit which never reaches maturity, so death of the embryo after conception is due, in some cases at least, to defects in the male parent. The fault is, as it were, *ab initio*. Conception takes place, but it is vitiated from the beginning by some alteration in the fecunding fluid. The male parent may be too young or too old to impart the necessary potency to the spermatic fluid, and so the product of conception breaks down and drops like untimely fruit because it does not possess the necessary amount of vitality to prolong its development. Debauchery, various diseases, and injuries from which men suffer were then alluded to as so deteriorating the constitution as to impair the procreating power, and so cause abortion in the woman. As pointed out by Dévilliers, procreating power is essentially distinct from that of development, and hence a man may possess the power to fertilise, but his whole strength may be expended in this act, and may not extend beyond, so that there is no further development. The faculty of development, too, is relative. Thus a weak man may impregnate a robust woman, and, by so much as she has strength to impart, the vitality of the germ may be carried on entirely under the influence of the woman. The lecturer had not been able to procure any precise information as to the proclivity to abortion in the wives of men who were the subjects of albuminuria or saccharine diabetes; but the general outcome of opinion is that during the progress of these maladies the vital powers become so exhausted that sexual power and desire fall into abeyance, and that it is only during the slighter forms of disease that they are likely to continue. Lead-poisoning not only injuriously affects the child *in utero* when the mother is the subject of it, but indirectly also when the father is affected. In this way it may lead to the death of the fœtus *in utero* and produce abortion or premature expulsion. The most potent, however, of all poisons in producing intra-uterine death at all stages of pregnancy is the poison of syphilis, and this whether the disease exists in the male or in the female parent. A woman who has shown no sign of syphilis in her own person may be impregnated by a spermatic fluid which carries with it so potent a syphilitic virus that in its development it sooner or later kills the product of conception, and this in its turn so poisons the maternal blood that the woman eventually becomes tainted with constitutional syphilis. Several instances in illustration of this indirect influence of syphilis in the male on conception were quoted from the experiences of Charpentier, Professor Harvey, Jonathan Hutchinson, and others.

2. *On the part of the mother.*—The same general causes which influence sterility are concerned in a greater or less degree in the production of abortion and premature death of the fœtus—viz., constitutional conditions, external agencies which depress the general health, extremes of heat and cold, climate, locality, &c. Over-feeding, Dr. Priestley is of opinion, is more pernicious in its effects on the product of conception than under-feeding. Anæmia in the mother may cause death *in utero*, and old age is not favourable to the continuance of pregnancy. Some acute diseases of a specific kind in the mother have a very marked and direct influence in destroying fœtal life: in proportion, *ceteris paribus*, to the gravity of the maternal affection, so is the danger to her progeny. Small-pox was given as an example, but scarlatina, measles, erysipelas, diphtheria, typhoid fever, and its congeners come within the same category. Of the non-specific forms of disease attended by fever, Dr. Priestley instanced pneumonia, which has always a special gravity when complicated by pregnancy, and which, if severe, almost invariably leads to emptying of the uterus. Pleurisy and the feverish state which follows surgical operations generally lead to abortion. Increase in the temperature of the mother increases the fœtal pulse, and *vice versâ;* and the experiments of Runge on the effects of high temperature on the gestation of the lower animals published in 1877 were reviewed at length, their results being as follows:—(1) The temperature of the fœtus is habitually higher than that of the mother, and keeps higher when the mother's heart becomes abnormal; (2) the fœtus dies solely from the heat before it becomes fatal to the mother; and (3) the temperature of the mother, if only raised for a short period to 41·5° C., is fatal to the fœtus, the danger not ceasing with the reduction of the mother's temperature to normal. These conclusions have been confirmed by a series of experiments recently performed under Dr. Priestley's direction by Mr. Tyrell Brooks in the physiological laboratory of King's College. In the course of these inquiries a marked difference was found between the vaginal, the uterine, and the fœtal temperature: thus in the cat, vaginal 98·2°, uterine 98·4°, fœtal 99°. In eclampsia fœtal death may be due to such elevation of temperature in the mother's body as is incompatible with the safety of the child, but when the temperature does not reach so high a standard the death must be attributed to uterine contraction producing imperfect aeration of the blood, or vitiation of the blood from uræmic poison. In phthisical women the tendency to abortion and premature delivery is greater than in healthy women. Diabetes, jaundice, heart disease, malignant cholera, and allied morbid conditions may destroy the product of conception by poisoning it *in utero*, or by inducing uterine contractions and premature expulsion. Several poisons act deleteriously on pregnancy—lead, arsenic, mercury, savin, and the like. The most pernicious organic poison is, however, syphilis, and in women who are its subjects, abortions often succeed each other in frequent

Digitized by Google

repetition, and with a persistency belonging to no other cause. Even when there are no external indications of maternal syphilis, the succession of abortions or of dead children in more advanced pregnancy is traceable to a latent form of the disease which manifests itself in this fashion. If a woman has syphilis before conception, she is much more predisposed to abortion than a woman taking the disease after conception; if conception and syphilis commence together, abortion and premature labour with a dead child are the rule, but treatment is more potent in preventing them; syphilis acquired after the mid-period of pregnancy has less influence on the child, and it may escape altogether. One of the ways in which syphilis brings about intra-uterine death is by producing disease in the fœtal appendages; the venereal poison is transmitted to the embryo through the maternal blood, and may affect any or all of the tissues in the gravid womb. Uterine congestion or displacement, leucorrhœa, oxytoxic medicines, and reflex motor actions induced by minor surgical operations (tooth-drawing, &c.), have the effects of inducing abortion in some cases. All surgical proceedings during pregnancy ought to be abstained from, but if such operation be absolutely necessary the time corresponding to the catamenial periods must be avoided, the uterus being at such times more irritable. Dr. Priestley concluded his lecture by briefly referring to the effects of persistent gastric irritation, vesical, renal and rectal irritation, ovarian irritation, and finally to the injurious influence of mental emotion—fright, anxiety, &c.

A Lecture

ON THE

NEW METHOD OF TREATMENT OF CONSUMPTION AND OTHER DISEASES OF THE RESPIRATORY ORGANS BY GASEOUS RECTAL INJECTIONS.

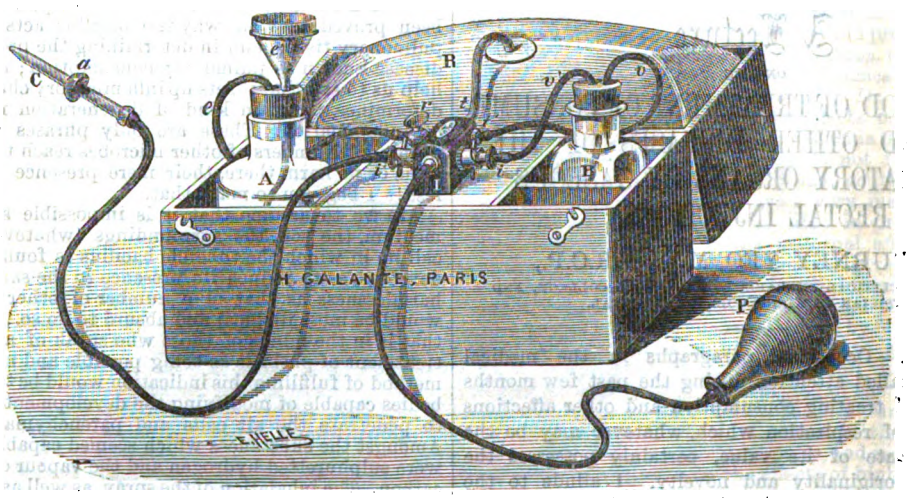
By I. BURNEY YEO, M.D., F.R.C.P.,

PROFESSOR OF CLINICAL THERAPEUTICS IN KING'S COLLEGE, AND PHYSICIAN TO KING'S COLLEGE HOSPITAL.

GENTLEMEN,—Occasional paragraphs in the medical journals have called attention during the past few months to a method of treating consumption and other affections of the organs of respiration which, whatever may be the ultimate estimate of its value, certainly possesses the characters of originality and novelty. I allude to the employment of gaseous rectal injections introduced and practised by Dr. Bergeon, a well-known physician at Lyons, and formerly a *professeur suppléant* in the School of Medicine in that city. Dr. Bergeon brought this subject before the Académie des Sciences and the Académie de Médecine in Paris through Professor Cornil, the eminent pathologist, last summer. Since that time it has been adopted by several eminent physicians in Paris, including Dr. Dujardin-Beaumetz of the Hôpital Cochin, Dr. Constantin Paul, and Dr. Chantemesse, Chef du Laboratoire de Bactériologie in the Faculty of Medicine; by Dr. Vaillet, Professor in the University of Geneva; by Dr. Queirel, Professor in the School of Medicine at Marseilles; and by other eminent practitioners of medicine on the continent of Europe. Our own countryman, Dr. Henry Bennet of Mentone, has written a warm eulogium of its effects, and has claimed for this method "serious consideration and trial." I have thought it my duty, as Professor of Clinical Therapeutics in this College, to make further inquiry into this method, to familiarise myself with its details, and to put it into practice before your eyes. In order to do this, I first communicated with my friend Dr. Leudet of Paris, who has had a very large experience in the treatment of affections of the respiratory organs at Eaux Bonnes, and begged him to inform me what impression his observation of this treatment had made upon him. He replied that there was certainly "something in it," and kindly offered, if I would come to Paris, to obtain for me opportunities of seeing it carried out there. I therefore at the end of last year paid a short visit to Paris for the purpose of informing myself thoroughly of the details and results of this method so far as at present ascertained. My best thanks are due to Dr. Dujardin-Beaumetz, to Dr. Bardet, the able Chef du Laboratoire Thérapeutique of the Hôpital Cochin, and also especially to Dr. Leudet for so kindly affording me all the information I required. I may say at once that I agree with Dr. H. Bennet in considering this method as having been attended with results which would make it culpable in us to disregard it or fail to avail ourselves of such opportunities as we possess to give it a fair and persevering trial. I am, moreover, disposed to believe that the local application of sedative gases and vapours, which this method makes easy, may prove of considerable service in other affections, and especially in the treatment of uterine and intestinal maladies.

Dr. Bergeon's original object was to discover some means by which the development of the tubercle bacillus should be hindered; this does not necessarily mean the destruction of the organism *in loco*, but the modification of its probable chemical action on the tissues, so as to render it harmless. And here I would like to point out that those who have been in haste to repudiate antiseptic medication as applied to the treatment of phthisis, because of the necessity, as inferred from laboratory experiments, of administering such large doses (if the bacillus is to be destroyed) as to render them actually toxic, have really been most illogical and unscientific in their imagined submission to scientific experiment. A narrowness of view is, I regret to say, not inconsistent with an assumption of scientific accuracy. It has not as yet been proved in what way the bacillus acts in destroying pulmonary tissue, and in determining the production of the disease known as pulmonary consumption; and it does not help us to say that it sets up inflammatory changes, and then determines a certain kind of degeneration in the products of inflammation. These are only phrases which explain nothing. Numbers of other microbes reach the lung and do little or no harm there, their mere presence proving harmless! I beg you to mark that.

Are we to assume that it is impossible so to alter the medium, the soil, the surroundings (whatever you like to call it) in which the tubercle bacillus is found and where it develops, as to reduce its presence to the same condition of harmlessness as that of a number of other microbes? It would be most illogical and absurd to do so. It is this idea that is in the minds of those who speak of an "antiseptic" treatment of phthisis as being possible and necessary. One method of fulfilling this indication would be to cause gaseous bodies capable of modifying the development of the bacillus to penetrate the air cells and parenchyma of the lungs. Amongst the substances which seemed capable of doing this were sulphuretted hydrogen and the vapour of bisulphide of carbon. The inhalation of the spray, as well as of the vapours given off by natural sulphuretted waters, and the administration of such waters by the stomach, have long been held in high repute, especially in France, in the treatment of consumption and other chronic diseases of the respiratory passages. In the autumn of 1876, some years before the publication of Koch's discovery of the tubercle bacillus, in a paper I contributed to the annual meeting of the British Medical Association on "Recent Researches in the Treatment of Phthisis," in referring to the use and action of sulphur waters, I used these words: "I am by no means sure that we shall not discover that many of our remedies for phthisis act *antiseptically* which are thought by many to act otherwise. May not the sulphurous mineral waters, such as those of Eaux Bonnes, act in this way?"



Other vapours were also tried by Dr. Bergeon, such as gaseous iodoform and eucalyptol. This observer had not been able to obtain all the good effects he desired from the use of antiseptic vapours by inhalation; and although, for my own part, I have had most convincing proof that such a mode of administration is attended with benefit in most cases, and with very remarkable amelioration in some, it requires a steadfastness of purpose and a constancy of application on the part of the patients and their friends, as well as on the part of the physician, that are but rarely met with. Without great thoroughness in this mode of applying antiseptic vapours, no doubt they penetrate but very imperfectly to the often diffused and deep-seated foci of disease; moreover, some of these gases would prove poisonous when admitted into the lungs by inhalation. This is the case with sulphuretted hydrogen, which is

Digitized by Google

highly poisonous when respired in certain proportions, and it produces serious effects on the blood-corpuscles when it passes into the arterial circulation. Diffused in *small* proportions through the atmosphere inhaled, it has for many years, as I have already stated, formed a part of the regular treatment of affections of the respiratory organs at sulphur spas, such as Eaux Bonnes, Luchon, Cauterets, &c.

It was through calling to mind the experiments of Claude Bernard on the absorption of gases by the large intestine that the method of gaseous rectal injection suggested itself to Dr. Bergeon. C. Bernard discovered that gases were readily absorbed by the large intestine, and that when thus absorbed they passed into the portal circulation, and thence into the pulmonary artery, and there came into contact with the pulmonary parenchyma, and were eliminated (if the dose had not been too large) through the lungs. He found that, if a small quantity of a weak solution of sulphuretted hydrogen were injected into the rectum, it was eliminated without any ill effects by the lungs; while the same quantity respired under a glass jar would be toxic. In administering gases by the rectum, it is, of course, necessary to inject only such an amount as can be readily eliminated by the lungs, otherwise the whole would not be separated and a portion would pass into the arterial system. After a series of test experiments, Dr. Bergeon found that by the method of rectal injection he could administer relatively large doses of antiseptic gases, and it was clear that in elimination they would be distributed over the whole parenchyma of the lungs, and so of necessity come into contact with the diseased parts. Having determined to ascertain the value of sulphuretted hydrogen given in the form of rectal injection, he had next to discover the best gas to be employed as a vehicle. On experiment it was found that atmospheric air, so far from being inert, was a very active irritant to the rectal mucous membrane, and finally carbonic acid gas was chosen because of its well-known anæsthetic properties, and because it is rapidly eliminated. The method employed by Dr. Bergéon was a very simple one. An indiarubber bag, holding from four to five litres, was filled with pure carbonic acid, and this was connected with an elastic ball, the working of which withdrew the gas from the bag containing it and drove it into a bottle—the "barboteur" as it is called in French,—which held a solution of sulphuretted hydrogen or of bisulphide of carbon. In its passage through this solution the carbonic acid gas became charged with the sulphuretted vapours, and this mixture of gases was very slowly injected into the rectum through a tube terminating in an ordinary bone cannula. In the apparatus constructed for this purpose by Dr. Morel, Dr. Bergéon's assistant, the carbonic acid was generated by adding dilute sulphuric acid to bicarbonate of soda. The gas given off was collected in an indiarubber bag, which, when filled, was detached and then connected with the bottle containing the sulphur water or other agent. The following were the objections to this apparatus:—1. That, as the injecting ball was placed in front of the "barboteur," it was difficult to feel the sensation of *resistance* offered by the rectum, as there was a long tube, as well as the fluid in the bottle, between them. This "resistance offered by the rectum" is sometimes very manifest, as we found in the first two cases in which we applied this method. 2. The use of *mineral* acid to generate the carbonic acid is attended with the risk of carrying over irritating sulphuric vapours. 3. The price was excessive—viz., 70 francs, or £2 16*s.*!

The apparatus which I have before me, and which we have used in this hospital, was devised by M. Bardet, the Chef du Laboratoire de Thérapeutique at the Hôpital Cochin, at the request of Dr. Dujardin-Beaumetz. It is manufactured by Galante et Fils, the well known instrument-makers, No. 2, Rue de l'École de Médicine, Paris, and it may be obtained from them at the moderate price of 35 francs (see woodcut). This apparatus has the great advantage of having all its component parts contained in one box, and is therefore easily transported from place to place; its manipulation and application are easily learnt, and may be entrusted, after a time or two, to an intelligent attendant, or even to the patient himself. Moreover, the carbonic acid is generated by means of a vegetable acid, which is neither toxic nor corrosive. It consists, as you see, first, of a "generator" (A), and a large glass bottle with a wide mouth, in permanent communication with the indiarubber bag or "reservoir" (B). In the generator the carbonic acid gas is generated, and for this purpose there are furnished with the apparatus small cartridge-like boxes, each filled with the necessary quantity of bicarbonate of soda and tartaric acid (separated by a partition of cardboard), in the proportion of twenty parts of

the former to sixteen of the latter, to set free enough carbonic acid gas to fill the reservoir, containing four litres. The "injector" (I) is worked by an elastic ball, or "pear" (P), which, with its tube, is outside the apparatus. This injector is provided with valves, which allow the gas to be aspirated from the reservoir (B) by suction action of the ball (P), and when the ball is compressed prevent the gas from flowing back into the reservoir and cause it to escape by the cannula (C). The bottle (B), called a "barboteur," contains the medicated fluid through which the carbonic acid gas is forced to pass on its way from the reservoir to the injector. The box, then, contains the following parts—a generator of carbonic acid (A), a caoutchouc bag or reservoir (B), a "barboteur" (B), and an injector (I). Outside the box are the injecting ball or pear (P), and the "cannula" (C) with the tubes connecting them to the injector. The injector, which is formed of an arrangement of valves (*i* and *i'*), is made of metal, and is, together with the other connecting portions of the apparatus (*r t t'*), combined together into a single solid block. The gas furnished by the generator (A) passes out by the tube *a*, which is connected at the tap *r* with the central metallic block, whence it escapes by the tube *t'*, through which it reaches the reservoir (B). It cannot escape by *t'*, as it is prevented by the resistance of the liquid in the "barboteur" (B). As soon as the reservoir is filled with gas the apparatus can be put in action. We compress the elastic ball (P), and the air it contains is driven out through the valve *i* and the cannula; then, when it re-expands, it tends to produce a

Digitized by Google

vacuum, and so opens the valve *i'* and aspirates the gas from the reservoir, which, passing through the tubes *t* and *t'*, reaches the "barboteur" (B) by the tube *v*, which descends to the bottom of that vessel; it becomes charged with the medicinal vapour in passing through the fluid contained in the "barboteur," and then escapes by the exit tube *v'* into the caoutchouc tube connected with the valve *i* and the injector (I); the ball (P) and the injector are then filled with gas. We then compress the ball, and the compressed gas opens the valve *i'* and escapes by the cannula (C), and so on until the reservoir is emptied.

Having described to you the different parts of the apparatus, I will now show you how it is worked. First, you fill the "barboteur" (B) rather more than half-full of the medicated solution you intend to employ (sulphur water, water impregnated with bisulphide of carbon, or hot water containing iodoform, terpinol, &c., in suspension), and you close it tightly with the cork. Secondly, you put a few drops of water into the generator (A) and then empty into it the soda and acid powder contained in one of the little cartridge-like boxes. You wait a few seconds in order that the air contained in this flask may be driven out by the small quantity of carbonic acid, which is set free by the few drops of water which you have placed in the bottom of the vessel previously. You then cork it firmly, and by means of the funnel provided with the apparatus you fill the generator about half-full of water, being careful to see that the tap *r* is open. As soon as the water is added the gas comes off freely, and in about two minutes fills the reservoir; shaking the flask will hasten the discharge of gas. The reservoir being filled, you work the elastic ball (P) three or four times in order to get rid of the air contained in the tubes and in the "barboteur," and then you introduce the cannula into the rectum. The ring on the cannula serves to regulate the length of tube introduced into the rectum and to maintain it there. The injection of the gas must be made very slowly and gently, waiting ten or fifteen seconds between each compression of the ball (P), and taking from twenty minutes to half an hour over the operation. The quantity of gas injected at each operation must depend chiefly on the tolerance of the patient—the minimum being one litre, the maximum about four litres. It is necessary also to take account of a certain amount of resistance to the injection on the part of the rectum encountered during the first two or three attempts with some patients. In this case it is well to wait a few minutes, and then to inject very slowly. As soon as the operation is finished it is necessary to empty and wash out the generator.

It has been stated that Dr. Bergeon, in order to obtain sulphuretted hydrogen in a pure and unirritating form, has hitherto been obliged to confine himself to the use of Eaux Bonnes water. Some bottles of this water are on the table before you. But an obvious inconvenience attends this limitation of the source of the sulphur gas, and, besides, the Eaux Bonnes water is but feebly charged with the gas, and some bottles are found unfit for use, as they yield little or no gas. We have had recourse here to the solutions suggested by Dr. Bardet for generating the sulphuretted hydrogen, and we have found them to answer perfectly. The first of these (No. 1), the sulphuretted solution, contains 10 grammes of sodium sulphide in 100 cubic centimetres of distilled water. This is made by passing pure gaseous sulphuretted hydrogen through a pure solution of soda, subsequently adding a weight of soda equal to that already employed, and then the water necessary to arrive at the strength indicated. A cubic centimetre of this liquid sets free exactly 10 cubic centimetres of sulphuretted hydrogen. No. 2 is an acid solution used for setting free the sulphuretted gas from the preceding; this is made by dissolving 25 grammes of tartaric acid and 1 gramme of salicylic acid in 100 cubic centimetres of distilled water. (The salicylic acid is simply to prevent the formation of mould in this solution.) One cubic centimetre of this solution entirely displaces the sulphuretted hydrogen of 1 cubic centimetre of the preceding. These solutions[1] afford us the means of estimating accurately the quantity of sulphuretted hydrogen administered. It is advisable, as Dr. Bardet points out, even when using a natural sulphur water, to add some solution of a vegetable acid, to set free the sulphur gas; if you do not do so, you will find the carbonic acid acts very slowly in setting free the sulphuretted hydrogen.

With regard to the dose, we have been using here the proportions indicated by Dr. Bardet as giving the best practical results—viz., 10 cubic centimetres of the sulphuretted solution to 200 grammes of water; this mixture is placed in the "barboteur," and 10 cubic centimetres of the acid (No. 2) solution is added. If all the sulphuretted hydrogen were set free from this and mixed with the carbonic acid gas injected, we should obtain a dose of sulphuretted hydrogen equal to 100 cubic centimetres. But there is always a little milkiness produced on the addition of the acid solution, due to the deposition of sulphur, and probably not more than two-thirds or three-fourths of the above stated quantity reaches the rectum, even when the full quantity (4 litres) of carbonic acid gas is injected. As to the quantity of carbonic acid injected, it varies from one to four litres, according to the tolerance of the patient. Dr. Bergeon directs that two injections should be given daily, but in Paris they rarely give more than one, unless the patient can only tolerate a small injection at a time, and then they also give them twice a day. At present we have only given them once daily. Those of you who have seen these injections administered will agree with me that apart from the odour of the gas there is nothing particularly objectionable in this method, either to the medical man or to the patient. But it must be admitted to be a troublesome method, when compared with our routine modes of treatment, and that it takes up much time When, however, we consider the vast amount of time we give to investigations in morbid anatomy, we ought not to complain because modern progress in connexion with experimental therapeutics throws on us additional labour and additional duties in this the most practical and most essential branch of our art. The trouble and labour attending the application of this method make it very desirable that it should be taken up and put into practice, not by one or two physicians only, but by a considerable number, for only in this way can its merits and applicability be tested in a sufficiently large number and variety of cases. Hitherto its application has been limited to affections of the respiratory organs, to phthisis, to asthma, and to catarrhal conditions of the air passages. It has, however, occurred to myself and to others that the injection of sedative gases and vapours by means of this apparatus may be destined to be of great service in other maladies, and especially in some painful uterine and intestinal affections.

Other agents besides sulphuretted hydrogen have been applied in the form of gaseous rectal injection with the aid of this apparatus. Iodoform in suspension in warm water has been placed in the "barboteur," and a mixture of its vapour with carbonic acid injected. It has been found of value especially in cases of fetid expectoration. Eucalyptol has also been used, but it has so far been found to be attended with so much bronchial irritation that its employment has not been persevered in. Terpinol has proved useful in phthisical and catarrhal cases with much fetid expectoration; the fetor of the breath has been agreeably modified.

This method is so new, and, so far as this country is concerned, so untried, that you will not expect me to express at present any very positive opinion as to its value, based on my own observations; but I will tell you what I have been able to gather from trustworthy observers. I will state to you Dr. Bergeon's own testimony, and put before you the results of our own observations so far as they have gone.

And, first, as to Dr. Bergeon's own testimony. He has stated that by this method phthisis, asthma, and chronic bronchitis can often be cured and nearly always alleviated. For more than two years he has been applying this method in cases of chronic diseases of the lungs and throat—more than two hundred in number—with an astonishing amount of success. In cases of early phthisis, he says, the disease is usually arrested in two or three weeks, and in a few months cured; and considerable amelioration is obtained in advanced incurable cases. It lowers the pulse, reduces temperature, checks the night sweats, restores appetite, diminishes greatly the amount of expectoration, and removes its purulent character, while the cough is greatly relieved. In advanced laryngeal phthisis he has observed rapid benefit when all other treatment has failed to give relief. Paroxysms of asthma are relieved more effectually than by any other means. Such is the testimony of the inventor of this method—testimony advanced not hastily, but as the result of two years of careful observation.

Dr. Chantemesse reports that he treated "nine patients in his wards presenting the general and local signs of pul-

[1] Those used in the Clinical Laboratory of the College Hospital were prepared by Messrs. Bell of Oxford-street.

Digitized by Google

monary tuberculosis with characteristic bacilli in their sputa, by Dr. Bergeon's method, and they obtained very great benefit. The increase of body weight was rapid—a pound and sometimes a kilogramme a week. Cough and expectoration were considerably diminished. The sputa, however, continued to present the characteristic bacilli of tubercle. They were under treatment for six weeks. One gained nine pounds in weight in that period." He also applied this treatment to two cases of very violent spasmodic asthma. He injected carbonic acid gas mixed with vapour of bisulphide of carbon. Half an hour after the first injection there was a very notable relief of the dyspnœa, and, the treatment being continued, the breathing became free and the paroxysms did not return during the whole course of the treatment. Commenting on the clinical observations of Dr. Chantemesse, Professor Cornil remarks: "So far we may say that rectal injections of carbonic acid and sulphuretted hydrogen gas constitute an excellent therapeutic method in phthisis as well as in asthma, and we ought to accept it all the more readily seeing how powerless are the therapeutic resources which we oppose to phthisis."

Dr. Morel,[2] alluding to the continued presence of the bacilli in the sputa of those restored to health by this method, suggests that their injurious influence is probably neutralised and their infectious properties destroyed by this mixture of gases; but he points out that unless this treatment be maintained in some degree, even in those restored to health, there can be no sense of security against a relapse so long as the characteristic bacillus appears in the expectorations.

In Geneva Dr. Bennet testifies he found several physicians adopting this method of treatment last September with "apparent benefit." He also states that in a case of very advanced phthisis under his own observation this treatment was "attended with an unhoped-for rally," and in a case of obstinate asthma he observed most remarkable alleviation.

Dr. Bardet, reporting the results of the observations at the Hôpital Cochin in Paris, says, "so far our results accord entirely with those announced by Dr. Bergeon. A rapid and constant sedative effect ensues, the cough diminishes rapidly, the patient sleeps much better, and the expectoration tends to disappear. These effects are very remarkable."[3] in Paris they were disposed to regard the carbonic acid itself as a valuable and important remedial agent.

As at present, we have only tried this method in this hospital for five or six weeks, and on a very limited scale, we have not been able to do more than corroborate some of the preceding statements. There is certainly no difficulty or danger in the operation, and we have not found it objectionable to the patients. We have observed a gain in flesh and strength, and an expression of general amelioration; the pulse, temperature, and respiration have fallen, and the expectoration has been diminished; rest at night has been improved. Beyond these statements of general improvement our data at present will not allow us to go. I have been much indebted to the co-operation of our excellent house-physician, Dr. Ewens, and particularly to my clinical clerk, Mr. Verdun, without whose valuable help it would have been impossible for me to have carried out a method of treatment requiring such constant personal supervision.

If bisulphide of carbon be the agent employed in Dr. Bardet's apparatus, it is necessary to empty the "barboteur" after each injection and wash it out with alcohol, and afterwards open the tap r, and by means of the elastic ball (P) drive air through the tubes so as to get rid of all the vapour of the bisulphide, otherwise it will rapidly make the apparatus unserviceable. I saw one case in Paris, a young girl in the cavity stage of phthisis, who had benefited much at first from this treatment, but subsequently it had to be discontinued on account of the difficulty she experienced in expectorating, so greatly was the expectoration diminished in quantity. Another patient also in advanced phthisis, in an adjacent ward, was clamouring for a renewal of the injections (which had been suspended) on account of the benefit he had received from them. No doubt the trouble attending this method of treatment will tend to render it unpopular with hospital attendants, and we must therefore be on our guard how we allow it to be discredited from interested motives. Dr. Bergeon maintains that when this method has failed it had [illegible]

[illegible]

ficient mode of application, and that if it is to be fairly tested it must be on the conditions he has laid down.

It must be admitted that new methods of treatment of phthisis are often submitted—and by those who should know better—to most improper and unsatisfactory tests. If the treatment we have been discussing, or any other treatment, were absolutely curative of phthisis, it could only be so under certain definable conditions. We may go further, and assert that if we possessed at this moment a certain cure for tuberculosis, it would of necessity leave a great proportion of existing cases of phthisis incurable. We should endeavour to realise this fact clearly, and to clearly comprehend what is the problem involved in the "cure of phthisis." To cure phthisis, we must begin to treat the disease before it has led to its most common result, the extensive destructive disintegration of lung tissue. No doubt local ulceration and loss of substance may occur, and cicatricial contraction and arrest of disease follow, when the surrounding lung tissue is sound; but this can only take place when the lung destruction is circumscribed and limited. Unfortunately, we too frequently have cases brought to us for treatment when all chance of curative treatment has passed away, and no matter what remedies we might have at our disposal, we could not work with them impossibilities. Yet we find experienced physicians testing "cures" of phthisis on advanced and hopeless cases of this kind, and reporting that the remedies are useless because they do not cure cases which are by no possibility curable. If the morbid changes which take place in the lungs in phthisis were actually open to our inspection, if we could see them instead of having them concealed from us, the idea of local medication of the lungs in the treatment of phthisis would, I feel sure, make rapid progress. The modification of the ulcerative, decomposing, and disintegrating changes, and tendencies to change, in phthisical lungs by antiseptic agents, which, in whatever form administered, have a local action, would appear to us imperative. Whether our antiseptic influences take the form of the pure aseptic air of the open sea, or of elevated mountain regions, or of pine forests, or of the inspiration of antiseptic vapours in well-ventilated apartments at home, or of antiseptic agents administered by rectal injection, or by hypodermic injection, which latter method is being largely employed in Paris at this moment, the principle is the same—viz., to exert an antiseptic and aseptic influence on the pulmonary or other affected tissues.

It is untrue to state, as some physicians have not hesitated to do, that the idea of antiseptic medication in phthisis has failed to be of much benefit. On the contrary, it has been productive of enormous benefit; and when the professional mind has overcome some of its prejudices and its narrowness of view and mode of thought, it is destined, I feel certain, to be of the greatest possible service. In connexion with this subject I was struck with the report by Dr. Neale in the *British Medical Journal* of Dec. 4th, 1886, of the excellent results he had obtained from what he called the "open-air treatment of phthisis." But what else had the patient besides a freely ventilated apartment? "Iodine is freely distributed about the apartment, and a pad of terebene placed under the chin when the patient is in bed. Food is pushed, cod-liver oil, with iodoform pills, and iron and belladonna, and oxide of zinc to control the night perspirations." I congratulate Dr. Neale on the signal success of his vigorous antiseptic medication. I could not wish a more thorough application of its principles: iodine vapour and terebene vapour to the respiratory passages; iodoform internally; fresh air always.

About the same time that Dr. Neale was pushing antiseptic treatment in the case he has reported, Mr. Pollard, of Queen Anne-street (in October last), brought a young gentleman to see me whom we both thought had but a very short time to live. He presented an aspect of marked cachexia, a temperature of 103° F. at midday, and rising even higher in the evening; physical signs of infiltration of the upper part of the left lung, with patches of dulness over both lungs behind, accompanied with blowing respiration and a pleuritic friction here and there. It is true the disease was of comparatively recent date, and there was no evidence of extensive destruction of lung tissue, but the fever was so continuous, the cachexia so marked, and the infiltration apparently so diffused, that we arrived at a very unfavourable [illegible]. We declined to sanction his leaving home, and pointed out to my friend Mr. Pollard that I considered the only chance of improvement, and that but a faint one,

Digitized by Google

rested in antiseptic medication. We gave him, internally, four minims of creasote in two teaspoonfuls of cod-liver oil three times a day, and prescribed the continuous inhalation of equal parts of terebene and eucalyptol. He had also a quinine and strychnine mixture as a general tonic, and some powders at night of bismuth and oxide of zinc to check the night sweats and tendency to diarrhœa. About three months afterwards I own I was somewhat surprised to see Mr. Pollard reappear with his young patient, and transformed. The results of this treatment had been most remarkable. Beyond the continued existence of the physical signs of some infiltration at the left apex, and some irregularity in the inspiratory expansion of the chest, as though from pleuritic adhesions, his condition was most satisfactory. He had gained much flesh; he had no fever, no night sweats, no dyspnœa, and not much cough. The cachectic appearances had vanished. I asked Mr. Pollard how he had contrived to obtain so striking a result. He replied that it was by a most thorough, painstaking, and conscientious adherence to all the details of the treatment we had agreed upon. When, gentlemen, we encounter such results as these from a method of antiseptic medication rigorously carried out, I think we are justified in saying, in the words of Dr. Leudet, "There is something in it."

Clinical Lectures ON DISEASES OF THE EYE.

Delivered at the Nottingham and Midland Eye Infirmary, December 9th, 1886,

BY C. BELL TAYLOR, M.D., F.R.C.S.,
SURGEON TO THE INFIRMARY.

LECTURE V.

EYE TROUBLES IN GENERAL PRACTICE.

GENTLEMEN,—I see no reason to doubt, and there is every reason to believe, that the operations you have just seen will end in the restoration of sight; and to restore sight to the blind has ever, and justly, been considered one of the grandest of human achievements. Brilliant and gratifying, however, as undoubtedly are the results of our most frequent ophthalmic operations, they are, after all, but as dust in the balance compared to the vast amount of human misery which is alleviated and the sum total of blindness which is prevented by the judicious treatment of the most common maladies to which our patients are subject, and which invariably in the early and most curable stages come under the notice of the general practitioner. Take, for instance, that most frequent of all the causes of blindness, the purulent ophthalmia of infants. There is no disease so easy to prevent, there are few diseases so easy to cure, and there is not one so fatal in its effects. If you will look over this work by Professor Corradi, entitled "La Cecité en Italie," you will find that there are upwards of 300,000 blind persons in Europe alone; and if you will glance at this graphic representation of the causes of blindness prepared by Dr. Magnus of Breslau, you will see at once that the purulent ophthalmia of infants stands at the head of the list; while if you will study, as I have done, the reports of the various blind asylums throughout Europe, you will find that from 30 to 46—ay, and 50 per cent.—of the inmates of these institutions owe their misfortunes to this terrible disease. Gentlemen, just consider what this means: it does not mean blindness coming on after a long life of usefulness or pleasure; it does not mean dimness of vision, admitting of more or less hopeful treatment; it does not mean damaged sight or blindness of one eye; it means blindness of both eyes—total, irreparable, coming on in the very earliest days of infancy, and lasting throughout the whole of many a long, weary, tedious, desolate life. Now this disease is not caused, as many have believed and taught (Stellwag), by cold, by a draught, or by sudden exposure to concentrated light. It is caused, as was first pointed out by our distinguished countryman Gibson, of Manchester, by the direct inoculation of the child's eyes with the secretions of the mother's vagina, and may be prevented as easy as easy can be by curing the leucorrhœa of pregnancy, by disinfecting or wiping away the discharge even so late as during the progress of labour, by insisting upon the most scrupulous cleanliness on the part of the attendants, so that their hands may not communicate infection, and by taking care that the child's face is not washed in the same water which is used for its bath, and that its eyes are not wiped with the same sponge that is used for its person. Gentlemen, if these precautions were thoroughly carried out in every case of midwifery, I venture to affirm that there would not be another case of bacterial purulent ophthalmia in the universe. Even if a little matter should have got into one or other of the child's eyes, it may be destroyed at once and *in situ*, before any harm is done, by a drop of a 2 per cent. solution of nitrate of silver;[1] and if one eye should unfortunately have become infected before you see the case—and, mind you, it is seldom that both eyes are struck at once[2]—the sound eye may be protected and sight assuredly preserved by the use of this little simple contrivance, this sticking-plaster shield, which I regard with parental, and I trust with pardonable, pride, since I am sure that I have saved many an eye by its use.[3] (Fig. 1.)

FIG. 1.

Gentlemen, I said the disease was easily cured, and so it is. Let me quote a little evidence on this point. Mr. (afterwards Sir William) Lawrence, late surgeon to St. Bartholomew's Hospital, whose work I have here—and I can cite no higher authority,—writing in 1833, says: "There is a singular contrast between the virulence of this inflammation of the eyes of newly born children, and the serious consequences to which that inflammation so rapidly leads, and the readiness with which it yields to suitable treatment; hence, if we see a case of purulent ophthalmia before any injury is done to the cornea, we may assure the parents, and it gives us great pleasure to be able to do so, that sight will not suffer. Even the most violent form is very manageable, and will do well when properly treated."[4]

Again, Professor Knapp of New York, another eminent ophthalmologist, whose archives I here commend to your notice, tells us, half a century later, that "no child need lose its eyes from ophthalmia neonati, and no child does if

[1] This is Credé's much-vaunted method: a solution of nitrate of silver, eight grains to the ounce, is dropped into each eye of every child born, "dans les services d'accouchement," and Dr. Kaltenbach, in a recent communication to the Congrès Allemand de Gynécologie declares that the cases of purulent ophthalmia have in consequence diminished from 15 per 100 to 0 per 100.—(See Recueil d'Ophthalmologie for August, 1886.)

[2] The ophthalmia almost always appears at first in one eye alone, the other being affected some days after. The transference of the secretion from one eye to the other seems to be the usual origin of the disease in the second eye.—(See Treatise on Diseases of the Eye, by Carl Stellwag, von Carrion Professor of Ophthalmology in the Imperial Royal University of Vienna, p. 317.)

[3] The shield is merely a piece of sticking-plaster with a hole in the centre, cut to correspond with the pupil; the aperture is filled by a piece of gauze. The baby depicted in the figure, whose left eye was attacked with a virulent form of purulent ophthalmia three days after birth, had its right eye protected in this way upwards of a fortnight.

[4] Lawrence on Diseases of the Eye, p. 171.

Digitized by Google

faithfully treated"; adding, "I speak from an experience, not of dozens, not of hundreds, but of thousands of cases."[5]

You will find a similar expression of opinion in this excellent *brochure* entitled "The Prevention of Ophthalmia Neonatorum and its Ravages," by Dr. David McKeown, of Manchester, presented to the Obstetrical Society of London in February last year; as also in this popular treatise entitled "Eyesight and how we lose it," by my distinguished *confrère*, Dr. Priestley Smith, of Birmingham. In short, gentlemen, not to detain you unnecessarily, I may say, without fear of contradiction, that on this point ophthalmic surgeons are agreed. The disease is easily cured. How is it, then, you will very naturally say, that so many children lose their sight from purulent ophthalmia? The reply to that question is simply this: either they are not properly treated or they are not treated in time. Let me prove this to you. Of 630 cases treated in an early stage of the disease by Professors Horner, Schweigger, and Hirschberg, 630—that is, every one—recovered with absolutely perfect sight. On the other hand, and I bid you mark the sequel, of 120 cases coming under the care of the same gentlemen, but not seen until a later stage, 49—that is, not quite one half, but more than a third—lost the sight of both eyes beyond all chance of recovery or possibility of improvement. Gentlemen, that is the trouble. The practitioner is called in when the parents are alarmed, or the specialist is consulted when the practitioner is alarmed, and then it is too often too late either to save the eye originally affected or to preserve the sound eye from inoculation. A few days ago—perhaps I ought to say nights, for it was after eleven o'clock—a cab dashed up to my door, the bell rang violently, and a lady with an infant in her arms was ushered into my consulting-room. "Dr. Bell Taylor," she exclaimed, bursting into tears, "will my baby see?" I ascertained that the child's right eye commenced to discharge three days after birth, some days later the left was inoculated from it, and both had been discharging freely for three weeks. All was supposed to be going on well. "The child was said to have a cold in its eyes," and, so far as I could learn, no special anxiety was felt as to the result, when suddenly it flashed upon the mother that her boy might lose his sight; and acting on the impulse of the moment, though late in the day, unfit to travel, and a hundred and fifty miles away, she rushed to the station and caught the train for Nottingham. I succeeded in arresting the discharge in a few days, but both eyes were lost from sloughing and ulceration of the cornea when she started on her journey. Gentlemen, this is a deplorable state of things; it ought not to be; and I can assure you that the various societies interested in the prevention of blindness look to you general practitioners who attend midwifery, and who have so much in your power, to save us from further reproach on the score of blindness from purulent ophthalmia. With regard to treatment, mycologists assure us that the virulence of the disease is due to the ravages of a gonococcus discovered by Neisser in 1879, which, like an elephant in a field of maize, battens on the cylindrical epithelium of the palpebral conjunctiva. It appears that the columnar epithelium of the bulbar portion of this membrane affords no nutriment to this microscopic specimen of the *feræ naturæ*; however that may be, it is an important clinical precept that our remedies must be sufficiently strong to disinfect the conjunctiva, and that they must be applied to the inside of the everted lids at least once in twenty-four hours. I have found chloride of zinc an excellent antiseptic myself; but the remedy *par excellence* is the nitrate of silver, which may be used in the form of mitigated stik, or 2 per cent. solution.[6] Meanwhile the matter must be worked out from underneath the lids, which must be prevented from sticking together by a little oxide of zinc and white precipitate ointment, and the eye must be kept saturated with alum-water or weak solution of chloride of zinc (one grain to the ounce), which may be iced or heated according to the nature of the case. If the lids are swollen, tense, red, and shining, they may be punctured, leeched, or painted with a solution of nitrate of silver in nitric ether; and if the cornea threatens to give way, the anterior chamber may be tapped and a compress bandage applied. You need not fear to separate the lids for the purpose of looking at the eye in the early stages of the disease, but later on the utmost care is needed. I was called to a case of this kind some time ago, a long way off; two surgeons were already in attendance, one a specialist. I said: "The cornea of the left eye is on the eve of perforation, and I think we had better give a little chloroform, tap the chamber, and apply a compress bandage." My ophthalmic friend dissented from this view, and proceeded to repeat my examination for himself. I was leaning over anxiously, I may say fearfully, watching the process, when, probably from some sudden motion of the child, the lens was projected with violence, and struck me in the right eye. By dint of free ablution and the use of antiseptics I was "quit for the fright," but it was a warning to me, and I am sure it will be a warning to you to be careful how you conduct an examination in the later stages of purulent ophthalmia. Apart from the danger to the child itself, the risk to attendants from carelessness in this respect is something greater than you can readily conceive. Let me endeavour to impress this upon you by a recital of two or three very important facts. 1. I have known a short-sighted nurse inoculated by pent-up matter, which spurted out when the adherent lids were suddenly separated. 2. Two friends of my own, surgeons, have each lost an eye from accidental infection. 3. It is a fact that 11·8 per cent. of the nurses in the St. Petersburg Hospital manage somehow or other to contract this disease from children under their care (Haussmann). 4. If you will refer to the reports of the foundling hospitals of Prague, of Vienna, of St. Petersburg, and the records of the Parisian *crèches*, you will find that a considerable proportion—from a fourth to a third (Fuchs)—of the baby inmates of these institutions contract this disease after admission, and may thus be said literally to be taken in and blinded at the public expense.[7] In order to avoid these deplorable accidents it is well that those who are much engaged in the treatment of these cases should wear large protective glasses. Sponges and syringes (the latter also because they are apt to injure the corneal epithelium) should be discarded, and all rags, linen, &c., which have been in contact with the discharge should be at once destroyed, for, as you will learn directly, it is dangerous to wash them.

Adults and others infected from children suffering from ophthalmia neonati present various degrees of purulent ophthalmia, according to the stage and virulence of the source of infection, and authors usually consider gonorrhœal ophthalmia under this head because it is marked by the presence of the same microbe and alike communicated by direct infection. There is no comparison, however, between the amount of reaction and destruction occasioned by inoculation with a mild fluor albus, such as most women suffer from some time or other during their lives, and that which follows the insertion of a particle of gonorrhœal matter into the conjunctival sac; indeed, in the latter case it is almost impossible to save the eye. Speaking on this point, Professor Arlt of Vienna says, "I have lost many eyes from gonorrhœal ophthalmia." Mark that, gentlemen. Professor Arlt is one of the most accomplished practitioners in Europe, and perhaps the most experienced; and if he, with all appliances and means to boot, cannot save the eye in the majority of these cases, it is clear that we have to do with a disease of exceptional virulence. Fortunately, however, in this affection only one eye is infected (unless when the patient has bathed his eyes with his own urine), and we can always guarantee the sight by protecting the sound eye with the shield to which I have already called your attention; and here let me beg of you to apply it on suspicion. This simple shade cannot, under any circumstances, do any harm; sight is not interfered with; ventilation is perfect; the patient is not prevented from helping himself or walking about; and its neglect is often attended with most disastrous consequences. Above all, let me beg of you not to believe the youths and young men, the most frequent subjects of this affection, when they tell you that they are free from venereal taint; for I have known even highly educated gentlemen deny the soft impeachment, when their shirts were stiff with discharge. We had a sad example of the results attending the neglect of the shield in the case of a poor woman from Grantham, who was here three months ago. Her right eye (it is generally the right eye) was inoculated from some

[5] Archives of Ophthalmology for March, 1882. Putnam's Sons, New York.

[6] If the remedies must be entrusted to the friends, the nurse may drop into the eye a solution of nitrate of silver, two or three grains to the ounce, thrice daily.

[7] At the meeting of the Imperial Surgical Society of Paris, on Feb. 21st, 1866, M. Giraldès (L'Union Méd., No. 823, et 26, 1886) reported that in the Hôpital des Enfants Trouvés the loss of eyes (sometimes even of life) by blennorrhœa neonatorum reached the enormous number of from 80 to 90 per cent.

Digitized by Google

linen she had to wash, and discharged freely for three weeks; at the end of that time, sad to relate, some of the matter got into the left eye, and when she came here both corneæ had sloughed. She was a widow, forty years of age, strong active, fond of work, and had two children dependent upon her. Of think of it!—hopelessly blind for life; and all for want of a bit of sticking plaster which any country druggist might have applied just as well as the most accomplished surgeon.

With regard to the treatment of gonorrhœal ophthalmia. "Dreadful diseases require dreadful remedies," and if you are to succeed you must be instant in their application. I usually apply leeches by the handful; pack the eye with ice, and, unless there is some contra-indication, keep it constantly applied; slit the outer canthus, incise and excise (if necessary) portions of the chemosed conjunctiva, and get the patient rapidly under the influence of mercury. During the crudescence of the disease, and when it is at its height—that is, during the first forty-eight hours, or while the discharge is serous,—strong caustics are out of place; but you may keep the eye saturated with weak solution of chloride of zinc (½ or ¼ per cent.)[s] from the beginning, and as soon as the serous discharge becomes purulent, apply as well once or twice daily to the inside of the everted lids a 2 to 4 per cent. solution of nitrate of silver, carefully protecting the eye by neutralisation with milk or saline solution. I have saved some eyes in this way, but occasionally the cornea will slough in twenty-four hours, and then all you can do for the patient, and that is everything, is to protect the sound eye from inoculation.

(To be concluded.)

THE GENESIS OF "BRIGHT'S DISEASE."

By J. MILNER FOTHERGILL, M.D.,
PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

THE prevalence of the morbid change so far best known by the term "Bright's disease" (from Richard Bright, who first wrote on the subject); its certain ending, sooner or later, in death; together with the fact that its course can be profoundly modified by proper and judicious measures: all combine to give the subject an intense interest for all—physician and patient alike. "Old age is not an entity, but a set of conditions predisposing to what we call chronic Bright's disease. And though to most this comes in natural course when the prime of life is run, yet to some old age is no matter of years and of averages, but the running down of a spring set for an individual." Such is the happy expression of Dr. Goodhart in his well-known Bradshawe Lecture before the Royal College of Physicians of London in August, 1885. It is a slow, gradual growth of the lowly connective tissue of the kidney at the expense of the higher kidney tissues. But the kidney-mischief is only a part of the morbid change. A like growth of lowly tissue is going on in the walls of the arteries—atheroma—rendering them inelastic and brittle. But what calls out the growth of the lowly connective tissue in kidney and artery? The irritation set up by the presence of uric acid (possibly accompanied by other forms of albumen-metamorphosis) in excess in the blood. In order to grasp the matter firmly we must look a little beyond mere clinical facts, so as to read these last aright. We see, in the gradual evolution of life, the reptile, the cold-blooded inhabitant of tropical swamps, casting out its excrementitious matter in solid form—i.e., urates. The uric acid formation still continues in the warm-blooded bird, which also possesses a solid urine. When the mammalia appear, they are found to have a fluid urine, and their form of excretion is the soluble urea. But vestiges of the earlier formation still cling with the tenacity of original sin; and a certain, if small, quantity of uric acid is daily voided by man himself. So that we still carry with us traces of our descent in other forms than the branchial arches—the gills of fœtal life. Indeed, the circulation of the fœtus is that of the higher reptile; and the uric acid formation is distinctly seen in intra-uterine existence. We have long been familiar with the fact that under given circumstances the human body reverts to the early primitive form of urine-stuff. As to gout, we have recognised its association with good eating, especially when accompanied by a lack of exercise. The sensuous monk of old, lazy, fond of good living, and addicted to wine-bibbing, was the typical gouty man. Now, it is the country squire, whose habits were active till gout in his feet cripples him, and then its fell clutch becomes tighter and harder; or the p'ethoric publican, whose pleasures are those of the palate. This was the gout which came of good living. "Gout is the disease of those who will have it," said Meade. But a number of cases of distinct gout were found under widely different circumstances. They occurred in spare beings, small fastidious feeders, whose trencher performances were conspicuous by their temperance. To this class the term "poor man's gout" was applied. It did not explain the apparent paradox, and this inability to explain it was regarded as an opprobrium to the medical profession. Doubtless a large proportion of the sufferers from poor man's gout were descendants of gouty ancestors; and only by the strictest regimen, as to meat and drink, could they elude the visitations of their hereditary foe. But the gouty ancestry was not present in all cases.

The late Dr. Budd held that sundry persons came into the world with what he called "insufficient" livers; and Dr. Murchison endorsed this view. Such livers revert to the uric acid formation very readily; and now poor man's gout stands revealed before us. Indulgence in animal food in excess reduced a normal liver to the uric acid formation. A congenitally insufficient liver reverts to the uric acid formation under an ordinary or even meagre dietary. The result is the same in each case. When the uric acid formation is established we find one of two consequences: either (1) the uric acid is gradually deposited in the body, in the articular cartilages by preference; or (2) is cast out by the kidneys, which, being constructed to excrete the soluble urea, are irritated by the presence of uric acid in excess; with the result of interstitial nephritis, or chronic Bright's disease. Often both are found.

Renal changes are by no means the sole morbid outcome of the uric acid formation. The cardio-vascular system feels its malign touch. A tight artery is the consequence of the blood condition, and, with that, changes in the arteries and the heart. The high blood pressure in the arterial system leads to hypertrophy of the left ventricle, and that, again, to secondary valvulitis of a progressive nature—probably due to the forcible closure of the valves; the mitral by the large ventricle; in the aortic by the recoil of the highly distended artery. Possibly in the latter there is a tendency to gouty deposits, as in the joints. The distension of the arteries leads to a growth of connective tissue in their walls, which lose their elasticity and become brittle—the atheromatous change,—and from these we get apoplexy and aneurysm; while angina pectoris vaso-motoria is called out by occasional spasm of the peripheral arterioles. Sooner or later the growth of connective tissue within the coronary arteries themselves cuts down the nutrition of the large heart, and fatty degeneration spreads throughout its structure. The failing heart leads, in its turn, to dropsy, albuminuria, and death. Indeed, we get a vast number of morbid outcomes in this widespread vaso-renal change, beyond the interstitial nephritis, which is spoken of as "chronic Bright's disease," or "renal cirrhosis," or "the gouty kidney," as it is variously termed. But the consideration here is restricted to what is truly "chronic Bright's disease," a renal change started by an impure blood, as Professor Hayles Walshe asserted in 1849.[1] The uric acid (and possibly other excrementitious matter of nitrogenised character, the products of albumen metamorphosis) irritates the kidney structures, and starts up a rank growth of the lowly connective tissue, or packing material, at the expense of the higher true structures of the kidney. Here and there in minute foci, scattered throughout its mass, mainly in the cortex at the outset, we find the destructive action at work. The lowly invader is preying upon the higher structures, like the Tartar Turk spread himself over the population of the Balkan peninsula, and

[s] I consider the constant application of these solutions of the utmost importance. Dr. Colles of Dublin, writing in the Dublin Quarterly, vol. xxxv. p. 5, declares that he has been singularly successful in cases of gonorrhœal ophthalmia with solution of nitrate of silver, one quarter of a grain to the ounce, injected every ten minutes for twenty-four hours, the strength being afterwards increased to half a grain to the ounce, and injected every half-hour.

[1] THE LANCET report: Bright's Disease not essentially a Renal Disease, but essentially and primarily a Blood Disease.

Digitized by Google

with the same result—destruction. Slowly and steadily one minute portion of the kidney after another is caught within the light touch of some soft growth of connective tissue; but as the latter dries up and hardens, it contracts, and the true tissue within its clutch is ruined—squeezed out of (functional) life and (anatomical) form. Bit by bit, and often very slowly, the process goes on, until the kidneys are rendered inadequate as depurative organs, and the blood is rendered toxic by being surcharged with waste of albuminoid origin. Then follow secondary inflammation set up by the toxic blood, or other truly uræmic complications, often desperate attempts on the part of the body to cleanse its blood. To call this widespread change a "kidney disease" is as much a misnomer as to apply "Pimlico" to the whole metropolitan area; and to seek for evidence of it in the renal secretion solely is as imperfect as would be an inquiry into the sanitary arrangement of Lambeth, however carefully conducted, as to the state of the whole area which discharges its sewage at Barking Creek. Casts of the renal tubules are truly the infallible evidence of renal destruction as to existence, if not as to extent. The character of the urine tells much: when it is copious and of low specific gravity we have only too good reason to decide that the injury is extensive and widespread. Sometimes albumen is present in the urine, but its significance depends upon its associations. Dr. Richard Bright found that when albuminuria coexisted with dropsy the kidneys were the seat of disease. But in the diagnosis of several practitioners the dropsy factor drops out of the calculation, and the diagnosis is made in its absence. Albuminuria and "chronic Bright's disease" are, however, not convertible terms by any means, nor the equivalent of each other, as is not unfrequently assumed.

Chronic interstitial nephritis is but one of the numerous morbid progeny of the uric acid formation, albeit an important unit. We are all familiar with this vaso-renal change, as it runs its course in the mesoblastic structures of the men of Norse type, large-boned and florid, giving joint-gout, cardio-vascular changes, chronic bronchitis, rheumatism, eczema, and secondary valvular disease in the large heart. That is one aspect of the vaso-renal change. But this is by no means the only aspect of this change. It may sometimes commence with primary kidney mischief, and consequent imperfect blood depuration. Far more frequently it starts from a congenitally "insufficient" liver. In persons of the neurosal diathesis or Arab type (to whom the term "neurotic" aptly applies), the phenomena are widely different. The mesoblastic tissues are comparatively untouched; while the hypoblastic and epiblastic tissues are the seat of suffering. These persons are of spare habit and complain of indigestion, acidity, and flatulence—matters of the hypoblast; of migraine, accompanied by vesical irritability, of palpitation, of failure of the heart's action, resembling syncope, except that they do not lose consciousness, and realise the horror of their condition—matters of the epiblast. In many cases cardio-vascular change is also present, and the migrainous neurotic is as liable to apoplexy as the red-faced, short-necked gouty man; the urine of the last is usually copious and clear, while in the neurotic the urine is often charged with lithates.

The migrainous neurotic of the uric acid formation is growing more and more common. Town populations have a tendency to grow smaller and darker, as anyone can see by comparing the living crowd with the worthies in effigy at Madame Tussaud's. They have a tendency to revert to an earlier and lowlier ethnic form, and are smaller in the bone. They are precocious, and the early development of the nervous system is accompanied by a deficiency or backwardness in the assimilative organs. There is an insufficient liver, which readily reverts to the uric acid formation; and this is aggravated by the fact that town dwellers eat more animal food than rustic populations of the wage class, while the latter have the advantage of plenty of oxygen. The town dweller works in ill-ventilated rooms, and his amusements are in-door in a vitiated atmosphere. With an insufficient liver, a meat dietary, and insufficient oxidation, the town dweller is the subject, more than all others, of the uric acid formation, with all its varied consequences. At Victoria-park Hospital I have under care at the present time a mite of a girl, not yet thirteen years of age, in whom all the phenomena of the migrainous neurotic are already present. The effect of town life is to produce a [illegible] race of [illegible] than the rustic population. Precocity is seen in early puberty, but reproduction is impaired; and Hayles Walshe, Mr. Cantlie, and others have shown that it is well-nigh impossible to find a true Cockney of the fourth generation. Dr. Ralfe informs me that of 800 inquiries made at the London Hospital only four resulted in genuine Cockneys of the fourth generation. The retrocedent race perishes either by sterility in the females, or their sparse progeny succumb to the diseases of childhood. These urban dwellers, the progeny of town-born parents, this retrocedent race, are the possessors of congenitally insufficient livers, and as a consequence are the victims of the uric acid formation. This liver reversion is the microcosm within the macrocosm. And Bright's disease is especially the disease of this urban race. Teetotalism and vegetarianism are no matters of mere caprice or fashion; but are the unconscious submission to an unseen law ruling the choice. The urban dwellers cannot tolerate the beef and ale of their rural forefathers. No doubt in many cases alcohol and syphilis play their part, and too often an important part. But these are only accessories to the great fact that the descendants of town dwellers die prematurely old of Bright's disease, and that the spring runs down at a much earlier period with them than with rural populations.

Many persons are remarking how common gout is becoming amidst us at the present time. Such is certainly my personal experience; though articular gout is by no means the common outcome of the uric acid formation in town dwellers. Sufferers from articular gout are comparatively infrequent among the crowd of persons who are undergoing that vaso-renal change to which "chronic Bright's disease" is the term most commonly applied. In other cases neurotics are found with the uric acid formation, who seem to owe their "insufficient" liver to hard intellectual toil on the part of their fathers. Nearly every American lady of this class has given me a history of the long and usually successful efforts of her father. "The fathers have eaten sour grapes, and the children's teeth are set on edge." There seems some law of antagonism betwixt the tissues of the epiblast and those of the hypoblast. Long sustained demand upon the brain as "the organ of mind" tells upon the viscera. The liver suffers therefrom; and the progeny of the hard-working brain-toiler comes into this world with an insufficient liver. Clifford Allbutt, F.R.S., some years ago pointed out clearly the mental causes of Bright's disease, in an address which attracted much attention at the time and since. Not only does my experience fall in with his as to the individual, but it seems to teach a further lesson—viz., that hard, sustained brain toil has its Nemesis in an insufficient liver, which reverts to the uric acid formation. The bright, high-souled migrainous-neurotic, one of the most charming patients who enter the physician's consulting-room, owes her fortune and her liver alike to her father's toil, which is rather a hard nut to crack for those whose ambition it is to make a fortune.[2]

Thus we see there are many factors—and some of them little suspected—at work in the genesis of Bright's disease. Nor is it inaccurate to say that it is a disease becoming daily more common in "this madly striving age." More familiarity with its causal relations ought to develop definite preventive measures.

Henrietta-street, W.

CASE OF

EXCISION OF TUMOUR OF CEREBELLUM.

By BENNETT MAY, F.R.C.S.,

SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

EARLY in August, 1886, my colleague, Dr. Suckling, informed me that he had a patient under his care in the hospital in whom he diagnosed a tumour of the cerebellum, which he thought might be amenable to operative treatment. Such a case did not at the outset offer to my mind much prospect of successful completion, on account of what I conceived to be the exceptional difficulty of access to a tumour in this portion of the brain. The actual procedure, however, I found to be extremely easy of accomplishment and of no great severity, and I believe that in some respects this

[2] No wonder Bright's disease is so prevalent among the hard-working inhabitants of the United States of America.

Digitized by Google

portion of the brain will be found not unfavourably placed for operative procedures. At any rate I wish to make this contribution as a practical inquiry in the study of a subject which is now engrossing so much professional attention. Although this case so quickly terminated fatally, there is no doubt whatever that this was owing to the valuable time which had been lost before the operation was performed, during which the child's vital powers became too greatly reduced to afford much hope of success. In all details of method I closely followed the lines laid down by Mr. Victor Horsley for the preparation of the patient and the treatment of the wound, &c. These appear to me to embody several points of considerable practical importance in brain surgery. In the case of another patient of Dr. Suckling's, whom I have just operated upon for epilepsy, complete primary union, without the slightest departure from normal health, has followed an extensive opening of the dura mater and exploration of the brain, and such favourable result appears to be almost the rule now. The following history and symptoms of the case are furnished by Dr. Suckling, who localised the position of the tumour with such accuracy that I was able to cut directly upon it at the spot he indicated.

"C. H——, a boy aged seven, was admitted into the Queen's Hospital on July 19th, 1886. The only important feature in the family history was that the father's uncle had phthisis. Twelve months previously to his admission the boy had rheumatic fever. In April, 1886, he suffered from severe and persistent headache, chiefly frontal, with vomiting. Since this time his sight had gradually failed. On admission, the pupils were dilated and unequal, but responded to light and accommodation. There was conjugate deviation of the eyes to the left, and paralysis of the external rectus muscle on the right side. There was intense neuro-retinitis on both sides, and the boy was nearly blind. The gait was staggering, the stagger being chiefly in the backward direction, but occasionally to the left side also. The mind was clear, the boy talking rationally and complaining that he could not see. The lungs were healthy. While in the hospital the boy vomited at times, complained of frontal headache, and gradually got worse, very soon being quite unable to stand. On August 20th marked retraction of the head was observed. On October 8th the boy was absolutely blind, and there was well-marked nystagmus. The knee-jerk was lost on the right side, and there was marked emaciation. The symptoms above recorded clearly pointed to a tumour in the cerebellum. The paralysis of the right external rectus led me to conclude that the tumour was in the right lobe of the cerebellum, and was growing downwards and forwards and compressing the right sixth nerve. It was thought also that it was most probable that the tumour was tubercular."

Owing to my absence from home in the autumn a regrettable delay of some weeks took place before the child was operated upon, and during this time his condition greatly changed for the worse, and he had become much collapsed in the few days preceding the operation.

Operation.—Full antiseptic precautions having been taken and the patient brought under chloroform, my first step was to expose that portion of the occipital bone which lies below the superior curved line, so that all proceedings could be carried on beneath the tentorium cerebelli. A curved incision with convexity upwards, and reaching a little above the external occipital protuberance, was carried across the back of the head from one mastoid process to the other. The scalp and subjacent parts were then carried down as a flap by separating all the muscular attachments from the bone, but more on the affected side (the right) than the other, until the neighbourhood of the foramen magnum was reached. The bone being well cleared and exposed, the trephine was applied about the centre of a quadrilateral space bounded above by the right superior curved line, below by the foramen magnum, and inwardly by the occipital crest, and the hole in the bone was freely enlarged by the bone forceps until a large quadrilateral space of dura mater was exposed. This was easily done owing to the thinness of the bone. Extreme bulging of the dura mater gave evidence of great intra-cranial pressure, and the membrane was then opened and turned up by incisions along three sides of the aperture in the bone. The cortex of the cerebellum appeared quite healthy, but at one spot, a little outside the centre of the exposed space, palpation gave an ill-defined feeling of hardness beneath the surface. I then incised the brain substance over this spot with a tenotome, and on entering the finger could detect the hard mass of a tumour nearly an inch below the surface. Having verified its tubercular nature by detaching a piece, I had no difficulty in digging it clean out of its bed by the handle of a small teaspoon. It was larger than a pigeon's egg, hard and horny on the exterior, and caseating in the centre. Hæmorrhage was trifling, and the child gave no evidence of any injury or disturbance to the brain. The dura mater flap was then fastened down and the outer wound closed, this flap affording an excellent protection and covering. Unfortunately the child's condition had sunk too low beforehand to permit of sufficient reaction, and he gradually sank and died of shock a few hours afterwards. No post-mortem examination was permitted, so I am unable to say whether any other tumour was present.

Birmingham.

TREES FROM A SANITARY ASPECT.

By CHARLES ROBERTS, F.R.C.S., &c.

As this is the usual time of the year for planting, pruning, and removing forest trees and shrubs, it is a fit time for considering the influence which trees exert on the sanitary surroundings of dwelling-places. The recent Parliamentary Report on Forestry shows that trees are now of little commercial value in this country; and we may conclude, therefore, that they are chiefly grown for picturesque effect, and for the shelter from the sun and winds which they afford. The relation of forests to rainfall has been studied by meteorologists, but little attention has been given by medical climatologists to the share which trees take in determining local variations of climate and the sanitary condition of dwellings, notwithstanding they play as important a part as differences of soil, of which so much is said and written nowadays. This remark does not apply to large towns, where trees grow with difficulty and are comparatively few in number, and where they afford a grateful relief to the eye, shade from the sun, and to a very slight extent temper the too dry atmosphere, but to suburban and country districts, where it is the custom to bury houses in masses of foliage—a condition of things which is deemed the chief attraction, and often a necessary accompaniment, of country life.

Trees of all kinds exercise a cooling and moistening influence on the atmosphere and soil in which they grow. The extent of these conditions depends on the number of trees and whether they stand alone, in belts, or in forests; on their size, whether tall trees with branchless stems or thickets of underwood; on their species, whether deciduous or evergreen; and on the season of the year. The cooling of the air and soil is due to the evaporation of water by the leaves, which is chiefly drawn from the subsoil—not the surface—by the roots, and to the exclusion of the sun's rays from the ground, trees themselves being little susceptible of receiving and radiating heat. The moisture of the atmosphere and ground about trees is due to the collection by the leaves and branches of a considerable portion of the rainfall, the condensation of aqueous vapour by the leaves, and the obstruction offered by the foliage to evaporation from the ground beneath the trees. The experiments of M. Fautrat show that the leafage of leaf-bearing trees intercepts one-third, and that of pine trees the half of the rainfall, which is afterwards returned to the atmosphere by evaporation. On the other hand, these same leaves and branches restrain the evaporation of the water which reaches the ground, and that evaporation is nearly four times less under a mass of foliage in a forest, and two and one-third times under a mass of pines than in the open. Moreover, trees prevent the circulation of the air by lateral wind currents and produce stagnation. Hence, as Mr. E. J. Symons has truly observed, "a lovely spot embowered in trees and embraced by hills is usually characterised by a damp, misty, cold, and stagnant atmosphere," a condition of climate which is obviously unfavourable to good health and especially favourable to the development of consumption and rheumatism, our two most prevalent diseases.

Now, if we examine the surroundings of many of our suburban villas and country houses of the better sort, we shall find them embowered in trees, and subject to all the insanitary climatic conditions just mentioned. The custom almost everywhere prevails of blocking out of view other houses, roads, &c., by belts of trees, often planted on raised

Digitized by Google

mounds of earth, and surrounded by high close walls or palings, from a foolish ambition of seeming to live "quite in the country." This is a most unwise proceeding from a sanitary point of view, and should be protested against as strongly by medical men as defective drainage and bad water-supply. Many houses stand under the very drip and shadow of trees, and "the grounds" of others are enclosed by dense belts of trees and shrubs, which convert them into veritable reservoirs of damp, stagnant air, often loaded with the effluvia of decaying leaves and other garden refuse, a condition of atmosphere very injurious to health, and answerable for much of the neuralgias of a malarious kind, of which we have heard so much lately. A very slight belt of trees suffices to obstruct the lateral circulation of the air, and if the sun be also excluded the natural upward currents are also prevented. As far back as 1695 Lancisi recognised the influence of slight belts of trees in preventing the spread of malaria in Rome, and the cold, damp, stagnant air of spaces enclosed by trees is easily demonstrated by the wet and dry bulb thermometer, or even by the ordinary sensations of the body. A dry garden, on gravel, of three acres in extent in Surrey, surrounded by trees, is generally three or four degrees colder than the open common beyond the trees; and a large pond in a pine wood twenty miles from London afforded skating for ninety consecutive days in the winter of 1885-6, while during the greater part of the time the lakes in the London parks were free from ice.

The speculative builder has more sins to answer for than the faulty construction of houses. He generally begins his operations by cutting down all the fine old trees which occupy the ground, and which from their size and isolation are more beautiful than young ones and are little likely to be injurious to health, and ends them by raising mounds and sticking into them dense belts of quick-growing trees like poplars to hide as speedily as possible the desolation of bricks and mortar he has created. It is this senseless out-door work of the builder and his nurseryman which stands most in need of revision from time to time in suburban residences, but which rarely receives it from a silly notion, amounting to tree worship, which prohibits the cutting down of trees, no matter how injudicious may have been the planting of them in the first instance from a sanitary or picturesque point of view.

The following hints for planting and removing trees may be useful to those persons who have given little attention to the subject. A tree should not stand so near a house that, if it were to fall, it would fall on the house; or in other words, the root should be as far from the house as the height of the tree. Belts of trees may be planted on the north and east aspects of houses, but on the east side the trees should not be so near, nor so high, as to keep the morning sun from the bedroom windows in the shorter days of the year. On the south and west aspects of houses isolated trees only should be permitted, so that there may be free access of the sunshine and the west winds to the house and grounds. High walls and palings on these aspects are also objectionable, and should be replaced by fences, or better still open palings, especially about houses which are occupied during the fall of the leaf, and in the winter. Trees for planting near houses should be chosen in the following order:—Conifers, birch, acacia, beech, oak, elm lime, and poplar. Pine trees are the best of all trees for this purpose, as they collect the greatest amount of rainfall and permit the freest evaporation from the ground, while their branchless stems offer the least resistance to the lateral circulation of the air. Acacias, oaks, and birches are late to burst into leaf, and therefore allow the ground to be warmed by the sun's rays in the early spring. The elm, lime, and chestnut are the least desirable kinds of trees to plant near houses, although they are the most common. They come into leaf early and cast their leaves early, so that they exclude the spring sun and do not afford much shade in the hot autumn months, when it is most required. The lime and the elm are, however, beautiful trees, and will doubtless on this account often be tolerated nearer houses than is desirable from a purely sanitary point of view.

Trees are often useful guides to the selection of residences. Numerous trees with rich foliage and a rank undergrowth of ferns or moss indicate a damp, stagnant atmosphere; while abundance of flowers and fruit imply a dry sunny climate. Children will be healthiest where most flowers grow, and old people will live longest where our common fruits ripen best, as these conditions of vegetation indicate a climate which is least favourable to bronchitis and rheumatism. Pines and their companions, the birches, indicate a dry, rocky, sandy or gravel soil; beeches, a dryish, chalky, or gravel soil; elms and limes, a rich and somewhat damp soil; oaks and ashes, a heavy clay soil; and poplars and willows, a low, damp, or marshy soil. Many of these trees are found growing together, and it is only when one species predominates in number and vigour that it is truly characteristic of the soil and that portion of the atmosphere in connexion with it.

Curzon-street, Mayfair, W.

A CASE OF TRANSFUSION.

BY WARRINGTON HAWARD, F.R.C.S. ENG.,
SURGEON TO ST. GEORGE'S HOSPITAL.

As the operation of transfusion is not a very common one, and as there are several methods of performing it, it may be worth while to relate an instance in which the method recently introduced by Mr. Annandale was used with good effect.

A boy, fourteen years of age, who had been in St. George's Hospital under my care for two months, with periostitis of the femur and chronic pyæmia, had suddenly a profuse hæmorrhage into the cavity of a large deeply seated periosteal abscess of the thigh. The abscess had been opened and a drainage-tube passed through it a week before. When seen by the house-surgeon the boy was very much blanched, and had lost a large quantity of blood. The hæmorrhage was controlled by plugging the cavity and bandaging the limb. The following day some more bleeding occurred, in spite of the bandaging, and when I saw him blood was oozing freely through the dressings, and the boy was in a state of collapse. The abscess cavity extended round a great part of the femur, and from the inner side of the thigh a little above the knee to the outer side near the great trochanter. It was therefore too large and deeply seated to lay open, and the boy's condition seemed to forbid the possibility of surviving an amputation. I therefore only enlarged the lower opening sufficiently to give access to the fingers, and then firmly packed the entire cavity with carbolised gauze, placed a pad over the femoral artery, and bandaged the limb firmly from the toe to the groin. But when this was done the boy seemed to be sinking. It was therefore decided to transfuse into him some of his father's blood. This I did, with the assistance of Mr. Dent, in accordance with Mr. Annandale's directions. A vein at the bend of the boy's elbow having been exposed by a short incision over it, a double catgut ligature was passed beneath it, and the loop of the ligature divided. The lower or distal ligature was then tied round the vein. The vein was next opened, and a glass tube or nozzle, having one end bevelled, and the other attached to a short piece of indiarubber tube, was inserted into the vein. The upper or proximal ligature was now tied in a single knot round the vein and nozzle. In the meantime, the boy's father was bled from the arm into a glass measure containing a freshly prepared solution consisting of forty-eight grains of phosphate of soda in two ounces of distilled water—i.e., a solution of the strength of 1 in 20. Six ounces of blood were received into the vessel, so that the mixture consisted of three parts blood to one part of the saline solution. This was constantly stirred with a glass rod and kept at a temperature of about 100° F. by surrounding it with hot water. A three-ounce glass syringe, previously washed out with the soda solution, was now filled with the mixture of blood and solution, and its nozzle being inserted into the indiarubber tube connected with the cannula in the vein, its contents were slowly injected. Nearly three syringefuls were thus injected (eight ounces of the mixture). The cannula was then withdrawn from the vein, the ligature tightened and secured, and the skin wound stitched together with catgut. The syringe while being used was kept surrounded by hot flannels, and all the apparatus was washed in distilled water before commencing the operation.

The effect was striking and immediate. The pulse, which before the transfusion was imperceptible, could again be felt in the temporal artery; the boy regained consciousness, and was able to speak and swallow; and from this time he steadily improved. The transfusion took place on February 10th, and during the two months which have since elapsed he has had no more hæmorrhage.

The operation is an extremely simple one, and seems to me

Digitized by Google

to have the great advantage over any of the other methods which I have seen or practised of being free from the difficulties and dangers due to the formation of coagula. Even the simplest apparatus is apt to become clogged if unmixed blood is passed through it, and I can say from experience of it that the complicated instrument of Dr. Roussel is not an exception. On the other hand, the mixture of the phosphate of soda solution with the blood, while it prevents its coagulation, seems to have no attendant disadvantage. The apparatus used is simple and portable, does not easily get out of order, and requires no special skill for its management. This method has on three other occasions lately been practised by Mr. Dewsnap, house-surgeon at St. George's: in one case with complete success—the patient, who was in a state of collapse and insensibility from hæmorrhage, was revived by the transfusion, and is now well; in a second with temporary improvement; while in a third the patient was too seriously injured to recover.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

AN AFFECTION OF THE NERVOUS SYSTEM DURING THE EXANTHEM STAGE OF MEASLES.

BY T. COLCOTT FOX, M.B. LOND., M.R.C.P.,
PHYSICIAN FOR DISEASES OF THE SKIN TO THE WESTMINSTER HOSPITAL, AND PHYSICIAN FOR OUT-PATIENTS TO THE VICTORIA HOSPITAL FOR CHILDREN.

THE perusal of Dr. Thomas Barlow's interesting paper on a case of Early disseminated Myelitis occurring in the Exanthem Stage of Measles, and the discussion thereon in the Proceedings of the Royal Medical and Chirurgical Society, has reminded me of a curious case of an affection of the nervous system, which came under my observation in 1884. Notwithstanding the very imperfect nature of the notes, I am induced to send them for publication in the belief that they will prove of some interest at the present time.

Milly G——, aged four years and a half, was carried into the out-patient room at the Victoria Hospital for Children on Oct. 13th, 1884, unable to walk or stand. She was fairly well nourished, of good physique, and had been a healthy girl until her present illness. She could move her limbs—for example, reach out the arms to take proffered things and bend the legs,—but the muscular effort was accompanied by a singular and marked incoördination, the limbs being slowly waved about until brought to rest again, when they remained quite quiet. There was considerable loss of muscular power, the left leg being stronger than the right. The grasp was manifestly deficient. The muscles were rather flabby, but not specially wasted. The child was noted to have a somewhat vacant look, but could see well; the pupils were equal and responsive to light; there was absence of face and tongue paralysis. The speech, however, was markedly affected, for, although words could be articulated, they were only formed slowly and by a distinct effort. The child's intellect seemed good. The tendon and superficial reflexes appeared to be normal, and there was neither ankle clonus nor anæsthesia.

The history I obtained from the mother was as follows:—Two months previously—i.e., in August—the child, who up till then had enjoyed good health, was attacked with measles. The mother described the rash and accompanying bronchitis and absence of sore-throat, and was convinced that the affection was measles. A little brother and two other children in the house were also attacked. As the eruption faded away at the end of about a week, a "vacancy of mind" supervened, the girl became "cross-eyed," and could not sit up or move her limbs. She did not sleep, looked wild, would not endure people in the room, and became very "spiteful," so that they could not feed her from glass vessels. She could speak, put her tongue out, and swallow without nasal regurgitation. Her appetite was enormous. The child was believed to be blind, and Dr. Edwards, of Chelsea, who saw the case in the course of a very busy practice, kindly tells me that he remembers observing a state of dilatation of the pupils with an absence of reaction to light, and hearing complaints of twitching of the limbs. She gradually improved, and fourteen days previously to coming to the hospital she was able to sit up. I admitted her to the wards, and take the following additional notes from the report of Mr. Shaw-Mackenzie, the registrar: There was no retention of urine. The movements of the head were incoördinate, and accompanied by a peculiar slow nodding in different directions and rolling of the head. Nystagmus was observed at times. The ophthalmoscope did not reveal any diseased condition. The deltoid, triceps, and biceps muscles on both sides were believed to be somewhat wasted, but the electrical reactions of the muscles generally seemed normal. The child remained in the hospital for some months and very slowly improved, being able to stand by herself for a moment or two on January 5th, 1885, and she was discharged, almost entirely recovered, on March 8th. Throughout her stay the temperature was normal. As the family have changed their residence I have not been able to trace the case further.

To this account I append some observations on James Henry G——, aged one year, the little brother who was attacked with measles at the same time as his sister. On November 13th, 1884, he was brought to me with pneumonia and pain in the left wrist. Up to that date there do not appear to have been any special nervous symptoms. I did not see the child again, but I give the mother's description of the subsequent course of the illness for what it is worth. The pain gradually extended up the left arm, accompanied by stiffness and "shaking," and the left leg became similarly affected. The limbs shook more than his sister's. The tongue was drawn to the left and quivered, the face was drawn, and one eye was turned right into the nose. On the 16th the child was seized with strong convulsions, in which both sides of the body worked, and which recurred every quarter or half hour all day and also on the 17th till 5 P.M., when the infant became "quite sensible," and he died at 1 A.M. on the 18th. The left foot was shaking till the last.

A CASE OF TUBERCULAR DISEASE OF THE TIBIA AND ANKLE-JOINT (RIGHT), TREATED BY SCRAPING AWAY THE MEDULLA OF THE FORMER, AND THE SYNOVIAL MEMBRANE OF THE LATTER.

BY E. HURRY FENWICK, F.R.C.S.,
ASSISTANT-SURGEON TO THE LONDON HOSPITAL, SURGEON AND PATHOLOGIST TO ST. PETER'S HOSPITAL.

CASES in which the medulla of bones have been thoroughly scraped away are few. Those recorded are to be found chiefly in foreign literature, the operation having been performed for chronic osteomyelitis (Bleckmann, Stoll, Petrowski, C. B. Keetley). The following case seems worthy of publication, not only for the novelty and success of the above-mentioned proceeding, which it exemplifies, but also because there was combined with that procedure a new operation of Volkmann's (Halle) for treating tubercular joints. This latter operation is called by him *Arthrectomia Synovialis*, and consists in the total extirpation of the diseased capsule of a joint, with preservation of the bony epiphyses. The ankle-joint in this case was submitted to a modification of this process, with complete success.

A little girl aged two, of typical strumous aspect and build, came under my care at the London Hospital in August, 1885. When I first saw her the right leg was noted as follows:—"The lower half of the right leg is swollen and inflamed; extremely tender. An inch above the internal malleolus there is the opening of a deep sinus, with large flabby granulations bordering it. Probing reveals caries. The ankle-joint is swollen and tender; its movements are restricted; the appearance of the joint is that of tumor-albus, with a tendency to suppurate."

The history of this case was as follows:—The child springs from healthy stock; is the first and only child of moderately well-to-do people of the lower middle class; has always been well fed. Ten months ago, without any assignable cause, the leg began to be swollen and painful, and the little patient lost flesh. She was taken to a children's hospital six months ago, and an incision was made over the lower end of the tibia. The wound never closed. She was an in-patient three months. The diagnosis was easily made as being disease of the lower end of the tibia, probably tubercular, with subsequent invasion of the ankle-joint.

Digitized by Google

Resection of ankle, with amputation if necessary, was proposed to and accepted by the parents. An incision was made over the sinus and the spongy periosteum raised from the bone; the sinus was then seen as a rounded hole leading into the end of the tibia; cutting forceps rapidly enlarged the aperture, and a small central necrosis surrounded by a dense caseous material was found in the end of the bone and removed. Incision was then prolonged along the inner side of the foot. The ankle-joint was dislocated outwards, cleaned, and examined. The cartilage of the tibial articulation lay loose in the cavity of the joint like a thin piece of orange-peel, and the astragalus itself was bare. The synovial membrane was everywhere transformed into the spongy, pink, gelatinous material characteristic of a tubercular joint. With a Volkmann's spoon, and here and there with a scalpel and forceps, this diseased structure was carefully removed. Finding the joint so distinctly tubercular, I re-examined the tibial wound and found more caseous material present in the medullary canal. I took a long-handled Volkmann's spoon and scraped away as much of the medulla up to the tibial tubercle as I could remove. The inside of the bone was then plugged with strips of iodoform gauze, and the foot brought into a rectangular position and there fixed by means of an appropriate splint. The wound was dressed with iodoform and wood-wool. The result exceeded my expectations: the medullary canal filled up with rapidity, the wound into the ankle-joint healed in two months, and the child was discharged with a gum-and-chalk casing. She is at the present time in apparently good health. She limps slightly, but this is due to a shortening which exists, the left leg having grown slightly longer than the right. The right tibia is thicker than the left one, and, curiously enough, there is some movement in the right ankle-joint, such as obtains in fibrous ankylosis. She wears an iron on that leg, to limit if possible the tendency to knock-knee on that side—a condition obviously induced by the difference in the length of the legs.

This case is a teaching one as regards the tolerance of the medulla. One is so taught to regard it as being highly resentful of interference that it has hitherto been treated with marked respect. The cases, however, in which the medulla has been scraped show that good results have been obtained; and there is no doubt that much conservative surgery will be the direct outcome of the knowledge now accumulating as to its physiological uses, pathological tendencies, and the amount of operative interference it will submit to.

A CASE OF PURPURA RHEUMATICA.

By G. CHILDS MACDONALD, M.D.

THE following case has recently occurred in my practice.

J. B——, aged twenty-nine, a blacksmith, married. Personal history satisfactory; does not remember ever having been ill, excepting cold, &c. Both father and mother alive and in good health; four sisters alive and healthy; one brother dead. The patient does not know the cause of his illness, but believes it to be due to some childhood complaint. He had not been feeling well for the last week, having suffered from headache and sharp shooting pains in the back and down the legs; he describes them as rheumatic in nature, so much so that his friends were afraid he was going to have an attack of acute rheumatism. Accompanying these pains was a sensation of cold, amounting occasionally to actual shivers; during this period he was extremely thirsty. The bowels were constipated, and sleep was restless and broken. No beer or spirits had been taken, excepting a small amount of brandy when the shivers came on; neither did he have any drugs or particular article of food. At 12.30 P.M. on March 4th he was taken with violent pain and stiffness in both popliteal regions, which became so agonising that he was unable to remain longer at work, and returned home, where, feeling very cold, he sat by the fire, the pain varying in amount, being sometimes better and sometimes worse, until 8 P.M., when he determined on going to bed; he had difficulty in getting upstairs, the legs feeling stiff and heavy. [illegible] sat on the edge of the bed previously to [illegible] the whole of the pain went as if [illegible] had become blood-red, and being naturally alarmed he immediately sought medical assistance. The patient is a well-developed man. Height 5 ft. 8 in.; weight 10 st. 10 lb. Skin somewhat pallid, but feels soft and moist. Pulse 82, quick, full, and hard; temperature beneath tongue 101°; tongue moist and clean. On the back of both thighs, extending from the gluteal folds downwards over the calves of the legs to about the middle, running to the inner surface of the thighs to the middle line in front, and on the legs to the crista of the tibiæ, is a red rash, most intense over the popliteal spaces, where it is uniform and somewhat raised; the rash on the inner surface of the thighs is similar in character; towards the periphery and in other places it is almost petechial. The whole of the involved areas of skin feel to the hand hot and dry; firm pressure has no effect on the colour, and it is unaccompanied by itching. The digestive, circulatory, respiratory, and genito-urinary systems are normal. Urine clear amber colour; reaction acid; specific gravity 1020; no albumen; no sugar. The patient was ordered a saline mixture, with three-minim doses of tincture of aconite in each dose, a ten-grain pill of colocynth with calomel at bedtime, and a milk diet.—March 5th: Has much improved; bowels relieved three times. Pulse 72; temperature 98·4°. There is no further extension of rash, which has become duskier in hue; no pain. Ordered a mixture of dilute sulphuric acid, tincture of perchloride of iron, and sulphate of quinine three times a day.—7th: Patient feels quite well. The eruption has entirely disappeared. Ordered to continue mixture for three days. Ordinary diet.

The points of interest in this case are the violence of the pain, its rheumatic nature, its sudden cessation, its complete symmetrical arrangement, and the rapid recovery, which is usually prolonged in these cases. Dr. Kinnicutt of New York has recorded similar cases in the *Archives of Dermatology*, vol. i., as has also Dr. Duhring in the *Philadelphia Medical Times*, 1873.

Duchess-st., Cavendish-sq., W.

CASE OF RHINOLITH.[1]

By E. CRESSWELL BABER.

N. B——, aged twelve, was admitted a patient at the Throat and Ear Dispensary on Dec. 16th, 1886. She had had an offensive discharge from the left nostril for six years, with bleeding. There was no known cause. Neither she nor her mother remembered anything being put into the nose; but when young she had a habit of swallowing cherry-stones. There is epiphora on the left side when she is exposed to the wind. On examination, the left side of the nose and the left cheek were bulged out; the left nasal passage was impervious to air, the nostril on that side being contracted and its edges excoriated. Anterior rhinoscopy showed, on the right, considerable deflection of the septum towards that side; on the left, the anterior naris blocked by large soft granulations. Behind these, and completely hidden from sight, the probe revealed a hard body about an inch and a half distant from the tip of the nose. On Dec. 18th, with the assistance of my colleague Mr. Treves, the patient being under chloroform, this body was removed through the nostril with scoop and forceps. Afterwards no roughness could be detected with a probe, and the instrument passed easily through into the naso-pharynx. Subsequent examination showed that the left nasal cavity was much dilated, allowing the naso-pharynx to be plainly seen through it. The inferior turbinated bone was much wasted, and presented a deep concavity about its centre. By cleansing the nostril and touching some remaining granulations with solution of caustic, the discharge has now (February 28th) almost ceased, and has entirely lost its disagreeable odour. No diseased bone has been detected. The left cheek still appears larger than the other, and the malar bone more prominent on that side, the inequality being apparently produced by the long sojourn of the nasal calculus. The rhinolith was more or less filbert-shaped, and had, as usual, a rough and mammillated surface. When dry it measured approximately 18×13×8 millimetres and weighed nine [illegible] section it was found to consist of tightly [illegible]

[1] Read before the Brighton and Sussex Medico-[illegible] March 3rd, 1887.

Digitized by Google

packed folds of ordinary rag, on to which the salts of the nasal secretion had become deposited.

Rhinoliths, which in spite of increased attention being directed to nasal subjects are still considered uncommon, usually have their origin, as in this case, in a foreign body introduced into the nose. The case just mentioned is, however, peculiar in the nature of the nucleus, and in the circumstance of such a soft body as a plug of rag having by the deposit which had taken place upon it produced no inconsiderable distortion of the neighbouring bones.

Brighton.

NOTES OF A CASE OF POISONING BY TARTAR EMETIC.

BY S. L. DOBIE,
SURGEON-MAJOR, 4TH MADRAS CAVALRY.

ON Jan. 6th, 1887, H. F——, male, Eurasian, aged fifteen, took by mistake about sixty grains of tartar emetic instead of Epsom salts. In ten minutes he broke out into a cold sweat and vomited. He was seen within a quarter of an hour of taking the poison. Vomiting was encouraged, and he was given tea, infusion of galls, gruel, and a small quantity of brandy during the day. Vomiting continued freely all day, and at night he was purged three times; was conscious the whole time.—7th: Vomiting continued; purging ceased; had milk and gruel; remained sensible.—8th: No vomiting or purging; doing well.—9th: About 11 A.M. he became feverish, then delirious. Had an enema, which acted; mustard and hot water to feet; mustard poultices to calves and nape of neck.—10th: Comatose; pupils widely dilated. Ordered enema of turpentine, which acted; six leeches to temples; counter-irritation to scalp, feet, and calves; blister to nape of neck.—On the 11th I was ordered into camp, and saw no more of the youth after the evening of Jan 10th. He remained comatose, was fed with spoonfuls of milk, and died at 2 A.M. on Jan. 12th, nearly six whole days after taking the poison.

The curious features in this case are that the patient lost the ordinary symptoms of antimony poisoning, seemed to be recovering on the third day, became delirious on the fourth day, and died comatose on the twelfth day.

GUY'S HOSPITAL.

SARCOMA OF THE FEMUR.—DEATH FOLLOWING NECROSIS OF THE LOWER JAW.

(Under the care of Mr. BRYANT.)

IN the case here recorded of sarcoma of the femur, the following points are chiefly of interest: the development of the disease after direct injury to the part; its malignancy, and extension to the interior of the knee-joint. Growth along the crucial ligaments would appear to be the usual mode of invasion of this joint, but the condition is rare; and it is easy to understand the increased difficulty experienced in diagnosis from primary joint disease. The second case is interesting from the extent of the disease, for which no cause could be found, and the fatal result.

CASE 1. *Sarcoma of the femur, spreading from an aperture in the bone to the periosteum and knee-joint; amputation of thigh; recurrence.* (From notes by Messrs. Bowes and A. Palmer).—C. P——, aged fourteen, a butcher's boy, was admitted on Sept. 16th, 1884. Three months ago he slipped down and knocked his knee. Slight pain was felt in the knee for a day or two; there was no swelling. About a week afterwards, as he was jumping over a hedge he again fell and knocked the same knee, which became painful and swollen; hot fomentations were applied. He consulted a doctor, who applied tincture of iodine and advised him to go to the Hertford West Infirmary, where he remained three weeks. Whilst there his knee was blistered. He was not confined to bed. The patient says the swelling began on the outer side of the knee and gradually involved the whole of the joint; it had been getting larger for the last three weeks, and was only painful at night, and then only at the back of the thigh.

On admission there was a large swelling over the right knee, involving the whole of the joint, most prominent on the outer side, where the swelling first began. There was no fluctuation, The popliteal space was very tense and tender, the tenderness extending along the flexor tendons up the thigh. The patella was quite superficial and movable, but did not float, showing that the trouble was in the joint itself. No glandular enlargement was perceptible in any part of the body, with the exception of one or two hard glands in the right groin. The knee was bent at an angle of 120°; it permitted of very little movement. There was also some thickening of the lower end of the right femur.

Sept. 16th.—Leiter's cold coil applied to the knee. The urine contains triple phosphates, but is otherwise normal.

18th.—The patient had much pain in the popliteal space last night, also in the back of the thigh. The front of the joint is tender. Appetite poor.

19th.—Chloroform having been administered, an exploratory incision was made near the outer condyle, and as a growth was found to exist the limb was amputated by anterior and posterior flaps. The muscles were found to be œdematous, especially in the posterior flaps, and a piece was removed. Silk sutures were applied, the stump was dressed with iodoform gauze, a back splint put on, a large drainage-tube introduced, and strapping applied between the sutures. On making an antero-posterior longitudinal section of the lower end of the femur and upper end of the tibia, the femur was found to be surrounded by a mass of new growth connected with the periosteum, and excavating the bone so that there was only a layer of bone about half an inch thick anteriorly in the lower end of the femur, the articular cartilage and bone representing the condyle to the extent of about one inch; all this was infiltrated with the growth. The bone was fractured immediately above the articular cartilage, and again three inches higher up, during the process of section. The posterior aspect of the femur three inches above the articular cartilage was entirely gone, hollowing out the substance of the bone, and forming a cavity filled with blood-clot and breaking-down growth. Projecting into the cavity was a spicule of bone about an inch and a half long, eroded, and continuous with the compact tissue of the bone-shaft on the posterior aspect. The tibia and patella were normal. In the joint were masses of growth, apparently coming through the capsule on the outer side, and passing forwards, on the one hand, over the outer condyle of the femur, and, on the other, to the outer margin of the articular cartilage of the patella; in both cases it could be raised off the articular cartilage, which did not seem to be affected by it; the growth also extended into the joint from the popliteal space, and here had run along the crucial ligaments, and apparently more or less destroyed them. The growth itself was a firm, opaque, whitish mass, with (especially along the anterior part of the bone) hard, radiating masses, which were doubtless points of ossification, feeling rough when scratched with a scalpel. What was left of the quadriceps muscle had a pale and more or less gelatinous appearance, and was very œdematous. Above the upper fracture the periosteum could be stripped off the bone, and appeared fairly healthy; but opposite to and below the fracture were fungating masses of growth which were fairly adherent to the underlying bone, and which on removal left it irregular and rough. The disease was clearly of a sarcomatous nature.

20th.—The patient passed a good night, with little or no pain, but says there is some throbbing of the limb. Evening temperature 102·2°.

24th.—The patient is going on well; very little pain. There are three or four glands in the groin, which seem to have got larger since the operation. Temperature 99°. Sleeps well; fair appetite; no cough. Limb dressed yesterday; there is a good free drainage, and the discharge (which is very slight) is quite sweet.

29th.—Stump dressed to-day; all the stitches taken out; limb looks well; drainage quite free, and only about three

Digitized by Google

teaspoonfuls of sweet discharge. A tonic containing iron and an occasional aperient were ordered.

Oct. 6th.—The stump is practically healed.

17th.—The stump is looking well, and the patient is up on crutches.

Nov. 2nd.—The patient slipped down in the ward yesterday, and hurt the stump a little.

28th.—Much fulness about the stump, and on the anterior part a hard roundish mass can be felt, but there is no tenderness. Circumference eleven inches.

December 12th.—Has complained of pricking pains in the stump for the last two or three days, and has been kept in bed.

15th.—Stump measured this morning: in circumference at ends of cicatrix 12½ in., and 9¾ in. in length from anterior superior iliac spinous process to end of stump. It is soft to the touch; tenderness only just behind external extremity of cicatrix.

25th.—The patient was sent to-day to Bognor Convalescent Home. He is afraid to use his artificial leg, as, after wearing it for two days, it caused a little inflammation in the glands of the groin, from pressure of the iron hoop round the top of the thigh.

February 23rd, 1885.—The patient was readmitted to-day, having fallen down whilst at Bognor. He has had great pain in the stump since. On examination there is a hard swelling, which seems like a nodular thickening of the end of the femur. No discolouration of skin or fluctuation can be felt. There is great tenderness of the stump.

March 9th.—The patient was discharged to-day. Stump swollen, and tender on moving it. The growth has recurred and the glands are also enlarged, so that any further operation would be useless. The stump on discharge was distended, firm, and tender, but neither the skin nor cicatrix had given way. The skin was normal in colour, but the veins were larger and well marked. On palpation in the loin some enlargement of the glands can be felt. The boy's spirits are excellent, his appetite is good, and there are no signs of secondary deposit in the chest.

CASE 2. *Necrosis of the lower jaw; death; necropsy.* (From notes taken by Messrs. Elliot and D. Jones).—M. H——, a woman aged forty-two, was admitted on Oct. 12th, 1885. With the exception of erysipelas of the face, which occurred twelve months ago, and congestion of the lungs, which she had five years ago, her general health has been good. On the 20th of June last the patient complained of cold, and her gums commenced to swell almost immediately; also the salivary glands under the tongue began to swell, until at the end of three weeks they had pushed the tongue up. During this time throughout the whole day she experienced a great secretion of ordinary saliva, which however, had a strong odour. Every morning when she got up her hands felt very cold and looked pale. They, however, assumed a better appearance as the day advanced. In three weeks' time the gums commenced to swell and the teeth to loosen. In four weeks' time the swelling in the submaxillary region commenced, and had gone on increasing. About this time her medical man was called in, who said that it was a case of necrosis of the jaw. He prescribed a strong tonic and a disinfecting gargle for her, and in a week's time the enlargement in the salivary glands subsided. No history was obtainable with regard to syphilis, mercury, phosphorus, injury, or carious teeth. She had not taken any medicine before her illness.

On admission there was a good deal of swelling about the maxilla, the skin feeling brawny and being of a dusky colour. On either side of the symphysis, below the inferior border of the bone, were two sinuses leading down to the bone, which did not appear to be quite bare, but was thinly covered with something soft. These sinuses discharged a fair amount of fetid pus. There was much tenderness about the jaw, and also great fixity, the patient not being able to open it more than an inch. She could not protrude her tongue. The teeth in the lower jaw were all loose, and the gums of both jaws and the mucous membrane over the hard palate were swollen and spongy, so as to overlap the teeth. Her breath was very fetid.

Oct. 15th: The two sinuses are distant respectively an inch and half an inch from the middle line. Bare bone was felt on probing. Ordered boracic acid and spirit gargle, with aperients, and to take fluid nourishment.

16th.—Temperature 103·2°.

18th.—Morning temperature 101·4°; evening 101·6°.

22nd.—During the last three days a large sinus has formed on the right submaxillary region, which leads down to bare bone. Four teeth were extracted.

25th.—Temperature last night and this morning 102 4°.

30th. Patient was very weak, and seemed semi-comatose. She could only open her mouth slightly, and the dresser could not make out what she tried to say. Her face was dusky, although the pupils were not unduly dilated. Had a startled expression when spoken to or touched. She takes all nourishment given her. Pulse very small, rapid, and weak. Respiration laboured (through nares), 46. She passes everything beneath her. Temperature 102 4°. Right submaxillary region presented an intensely fetid, oval, phagedænic ulcer, about three-eighths of an inch deep, three inches and a quarter before backwards, and two inches above downwards, extending from the middle line to about a quarter of an inch behind the anterior border of the masseter, the skin over which was dragged down in small vertical wrinkles; its edges were slightly everted, and not red. The base presented a large grey-black mass of shreds, not coming away easily. The attempt to remove what appeared the loosest shreds caused great pain. Superiorly the ulcer had extended just over the interior margin of the mandible, which was exposed and eroded; and posteriorly it had passed over the facial vessels; but as yet there was no hæmorrhage. In the base of the ulcer were some rounded pits, but it could not be seen whether they communicated with the buccal cavity; on holding a mirror over them, at the same time preventing escape of air through the nares, there was no sign of air coming through them. Discharge fetid and copious.

31st.—The patient had an injection last night; she slept well. She still takes a good deal of nourishment, but is much weaker than yesterday. The wound has been dressed twice each day with boracic acid and iodoform, but the wound is very fetid. Temperature 102 6°. The patient passed into an unconscious condition and died quietly.

Necropsy (conducted by Dr. Goodhart).—A partial examination only was permitted. On opening the mouth widely the hypertrophied condition of the gums was very marked. In the upper jaw it formed a thick ridge just within the row of teeth, giving the appearance of a second row. The anterior edges of the gums also overlapped the teeth very extensively. On examining the wound, a large piece of the lower jaw (right side) was seen to be necrosed; this was removed, carrying with it a few loose teeth and the altered gum tissue. It was found that there was a large piece of the lower jaw quite loose in the mouth; this was also removed, and proved to be the inner surface of the horizontal ramus of the lower jaw, as it formed a complete cast of its dental arch. The muscles beneath the tongue and soft parts forming the floor of the mouth were sloughing. The lungs were not examined, but the patient probably died of septic pneumonia. A section of the hypertrophied gum had the appearance of inflammatory tissue.

LEEDS GENERAL INFIRMARY.

COMPOUND FRACTURE OF THE SKULL; TREPHINING; SPASM OF MUSCLES OF FACE AND ARM; SECOND TREPHINING OVER THE FISSURE OF ROLANDO; RECOVERY.

(Under the care of Mr. M'GILL.)

FOR the notes of the following case we are indebted to Mr. J. Holt, house-surgeon:—

J. T. S——, aged thirteen, was admitted on February 9th, 1887, with a compound fracture of the skull. Shortly before admission he fell twenty-three feet on to his head; he does not remember receiving the blow, and was unconscious for a few minutes after the accident, but soon recovered his senses.

Condition on admission.—The patient is quite conscious, talks sensibly, and answers questions intelligently. There are no cerebral symptoms or constitutional disturbance. There is a compound fracture of the left side of the vertex of the skull, the skin wound being one-third of an inch in length. This is situated near the parietal eminence, and can be marked out exactly as follows: Take a point one inch and a half behind the centre of a line drawn from the root of the nose to the external occipital protuberance; from this point draw a line vertically downwards to the level of the upper border of the pinna of the ear; the centre of this last-named line corresponds with the position of the wound. Through the wound a depression can be felt in the

Digitized by Google

skull, and there is a small escape of brain substance. In the absence of symptoms it was determined not to trephine, but to dress the case antiseptically. This was accordingly done, the scalp being shaved, the wound and surrounding skin being irrigated with corrosive sublimate solution, and an antiseptic dressing applied.

Feb. 10th.—The patient has passed a quiet night. The pupils of both eyes are dilated, the right more so than the left; the right pupil does not respond to light. He is very drowsy, is roused with difficulty, but when roused seems quite sensible. In the evening it was determined to operate. The boy being placed under ether, the dressings were removed. The scalp felt soft and infiltrated for a couple of inches in all directions round the wound. Mr. M'Gill made a large crucial incision, leaving the original wound at its centre. From this point a fracture was seen extending upwards towards the vertex, and another backwards towards the occiput; both these fissures passed out of the region exposed by the reflexion of the scalp; at the junction of the two the skull was comminuted, these portions being depressed below the general level. Two of these, irregular in shape and one inch and three-quarters of an inch accross in their longest diameter, were removed, while the third was elevated. A small opening in the dura mater, through which brain substance was protruding, was seen. The edges of the skin wound were brought together by a few points of suture, small drainage-tubes being inserted in each of its four extremities.

11th.—Still drowsy. Slight facial palsy on the right side was noticed in the evening.

During the next two days there was not much change, the general drowsy condition was slightly improved, and the facial paralysis, though still slight, became more marked.

14th.—In the morning the right arm seemed weaker than the left, otherwise the condition is unaltered. The wound on the scalp looks healthy; there is no further protrusion of brain substance. At 7 P.M. the muscles on the right side of the face were attacked by clonic spasm, and during the night till 9 o'clock the next morning he had fifteen attacks of a similar character. All the muscles on the right side of the face were in a state of clonic spasm, the contractions numbering about 40 per minute; drawing up of the angle of the mouth and closing of the eye were particularly marked; on one occasion the patient bit his tongue. His head was twitched to the right side, the contractions of the platysma being clearly visible. The attacks last from three to five minutes; between them he sleeps, but seems to know when the fits are coming on, as he puts his handkerchief into his mouth to protect his tongue. In the second and third attacks the right arm was slightly affected, and in the seventh, at 3.45 A.M., the arm muscles were violently convulsed, and the leg also slightly implicated. After that time the spasms in the arm were as violent as those in the face, the whole limb being attacked, and the fingers, wrist, and elbow being alternately flexed and extended. Nothing further was noticed in the leg; its reflexes, superficial and deep, were normal. The optic discs were also in a normal condition.

15th.—At 9 A.M. there was a more prolonged attack, the right face, neck, arm, and forearm being violently convulsed. After this the patient seemed much exhausted. Mr. M'Gill determined to trephine at once over the lower end of the fissure of Rolando. Chloroform was administered, and a large flap, three inches across at the base and two inches and a half deep, was turned downwards, the anterior part of the former incision being utilised for the purpose. This flap, which included the upper part of the temporal muscle, having been reflected, the pericranium over the upper part of the temporal fossa was turned down, and a trephine one inch in diameter was applied a little in front of the centre of the lower antero-parietal area of Turner. The circular portion of bone was removed, and the dura mater, in which a large branch of the meningeal artery was visible, was exposed. This was next divided along the upper margin of the opening and a flap turned downwards, the artery in it being tied. There was slight hæmorrhage from the brain substance, which was arrested by sponge pressure. Nothing abnormal having been found, the dura mater was replaced and held in position by two fine catgut sutures; a small drainage-tube was inserted between it and the brain substance. The pericranium was next stitched up by another row of sutures; and, lastly, the skin flap was held in position by a few stitches, two drainage-tubes being placed at the most dependent angles of the wound. The operation was concluded at 11 A.M. At 1.50 P.M., the effect of the chloroform having passed off, he was convulsed as before in the face, neck, and arm. In the next twelve hours there were sixteen similar attacks. Then there was an interval, no fit occurring between 1.20 A.M. and 7.30 A.M. on the 16th. Till 7.15 P.M. there were eight attacks; the last one was of great severity, with increased frequency of the muscular contractions (120 per minute), and lasted for forty-five minutes. After this there were only four more fits, of gradually diminishing intensity, the last being at 2.50 A.M. on the 17th.

19th.—Wounds dressed and drainage-tubes removed; they look healthy and are healed in their deeper parts. The paralysis both of face and arm is much less marked. Two days later (Feb. 21st) the paralysis had almost entirely disappeared. From this date there is nothing special to remark; his convalescence was rapid, and on March 22nd he left the hospital with the wounds entirely healed and apparently in perfect health.

Remarks by Mr. M'GILL.—1. No operation was performed when the patient was admitted, there being no cerebral symptoms. This, though perhaps hardly orthodox, appears to be a reasonable proceeding. Few surgeons would operate for a simple depressed fracture of the skull without symptoms, and as by means of antiseptics the compound can be converted into what is practically a simple fracture, the same rule should apply. Apart from theory, experience proves that many cases of depressed compound fracture of the skull treated without operation make rapid and permanent recoveries. 2. How far the trephinings in this case influenced the result it is difficult to determine. It is possible that the operation and the arrest of the fits did not stand to one another in the relation of cause and effect. On the other hand, though no lesion was found, it is possible that some change of cortex existed at a short distance from the trephine opening, and that the relief of tension due to the operation was the cause of the favourable result.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Abdominal and Thoracic Aneurysms treated by the introduction of Steel Wire into the Sac.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Dr. J. J. PRINGLE contributed a paper on a case of Aneurysm of the Abdominal Aorta treated by Laparotomy and the introduction of Steel Wire into the Sac. The patient was a man, aged forty-six, admitted to the Middlesex Hospital with the symptoms of aneurysm arising from the upper part of the abdominal aorta; there was no appreciable sign of cardiac or general arterial disease. Treatment for a month by rest, appropriate diet, morphia, and full doses of iodide and bromide of potassium was futile, the increase of the aneurysm being evidenced by aggravation of pain, extension of pulsation, and the development of a diastolic in addition to the systolic bruit previously present. The operation described was performed by Mr. Henry Morris, full details being given in the paper. The principal difficulties encountered were: (1) the introduction of the wire, which was coiled on a roller, into the cannula, necessarily held deep in the abdomen; and (2) the adjustment of the cannula between the outward force of the pulsation and the inward force of pressing the wire into the sac. Only about a foot of wire was introduced before an insurmountable kink stopped its further progress. No hæmorrhage of importance complicated the operation. For two days the patient progressed satisfactorily, but he subsequently became almost maniacal, and died of asthenia five days after the operation, his highest recorded temperature being 100·6° F. At the necropsy both sides of the heart were distended by mixed clot; there was no peritonitis beyond a narrow line of adhesion between the operation-wound in the parietal peritoneum and the subjacent viscera. The aneurysm was found to arise from the aorta at the level of the coeliac axis, and to be very saccular and filled with clot, more than one-third of which was laminated and presumably due to the procedure adopted. The remarks touch briefly upon the significance of the diastolic bruit present and the

Digitized by Google

advisability of giving ordinary medical treatment a protracted trial in similar cases, but refer principally to the treatment ultimately resorted to. The statistics of *proximal compression* of the aorta are analysed, and the results regarded as probably less satisfactory than recorded experience would appear to show, whilst the procedure is obviously inapplicable to the majority of aneurysms of the abdominal aorta, which arise too near the diaphragm. The records of *distal compression* are discouraging, as are those of *galvanopuncture* in similar cases, whilst the remarkable success obtained by Loreta, of Bologna, by the treatment here adopted justifies its trial. The result of that trial presents many encouraging features. Mr. Henry Morris adds remarks commenting upon the advantages of steel wire over fishing-gut or horsehair, advocates in future having the wire coiled on a reel held by the operator to enable it to be paid direct into the cannula, and suggests for discussion the question, "What is the smallest quantity of the foreign body which must needs be introduced to excite the requisite formation of clot?"

Dr. W. H. WHITE and Mr. PEARCE GOULD communicated a case of Sacculated Aortic Aneurysm treated by the introduction into the Sac of thirty-two feet of Steel Wire. The patient, a powerful man aged forty-eight, had noticed a swelling of the front of his right chest for five months before he came under Dr. White's care. Two months later cough and dyspnœa on exertion supervened. On his admission into the hospital on Nov. 20th, 1886, a prominent swelling was found in the position of the right mamma, extending from the second to the fifth rib, and from the edge of the sternum to the axilla; it was the seat of a forcible expansile pulsation, and over it was heard a harsh systolic murmur. Above the chest anteriorly, and down to the angle of the scapula behind, the resonance of the right chest was much impaired, and the respiratory murmur was distant and weak. The man was kept in bed, on a restricted diet, and was ordered fifteen grains of iodide of potassium three times a day. He continued about the same until the second week in January, 1887, when he was much excited, and the swelling was noticed to increase rapidly in size and to become very prominent. It was then decided to employ Moore's treatment, and on January 11th Mr. Pearce Gould passed thirty-two feet of steel wire into the aneurysm through a Southey's cannula, introduced in the third intercostal space. A good deal of blood was lost during the operation, but the hæmorrhage was quite stopped by a pad of lint. The tumour became harder, and the pulsation more heaving in character, and from one of the punctures (two had been made) reddish serum continued to drain in considerable quantities for several days. Accordingly, on January 17th the pad of lint was fastened on more firmly; next day there was observed great swelling of the subcutaneous tissue over the aneurysm, and on the 19th the skin was found to be gangrenous, and in a few hours the patient died. At the necropsy the first part of the arch of the aorta was found dilated to the size of a large orange, and springing from the upper part of this dilatation was a sacculated aneurysm the size of a cocoa-nut. The intra-thoracic portion of the tumour had a distinct but thin sac, but that part which protruded from the chest was destitute of a definable sac, and was limited by infiltrated muscle. The wire together with loose fibrinous clot formed a very dense mass, nearly filling, but not adherent to, the sac. The authors suggest that the fatal result was largely due to the absence of a distinct sac to the outer part of the aneurysm, and to the effects of the formation of a very hard solid mass in the aneurysm, combined with rather firm external pressure applied for the arrest of the serous oozing. They submit the following conclusions: 1. Moore's treatment is worthy of further careful trial in properly chosen cases. 2. The operation should be performed before there is reason to suspect rupture of the sac. 3. Only a small quantity of wire should be introduced at any one time. 4. No firm pressure should be made over the aneurysm afterwards.

Mr. J. W. HULKE related a second case on which he had recently operated. The treatment was absolutely innocuous, and perhaps slightly beneficial. The patient was a sailor, who fell from a height on Oct. 13th, 1885, and three weeks after the accident a swelling appeared at the root of the neck on the right side. For this aneurysm he was treated with some success at St. Mary's Hospital. On Aug. 19th, 1886, he was admitted into Middlesex Hospital, under the care of Dr. Cayley, who, with Dr. Douglas Powell, diagnosed a large aneurysm probably of the innominate and aortic vessels. After rest in bed and a large dose of iodide of potassium the patient was placed under strict Tufnell treatment from October to January, 1887, with the result of a slight diminution in the size of the aneurysm, but without real improvement. He left the hospital only to return in a month, and on the same day of his readmission, Feb. 24th, for increased pain and swelling in the aneurysm, of which the coverings were extremely thin, Mr. Hulke introduced thirty-three feet of steel wire. There was no trouble at the operation, and the wire was introduced through a cannula, hand over hand. After its introduction palpation revealed some degree of hardness of the sac. On March 1st there was increased pain and much arterial tension, which was relieved by bleeding to the extent of five or six ounces, enabling a good night's rest to be obtained. The man died on the 9th—i.e., thirteen days after the operation. The aneurysm examined by Mr. Leopold Hudson appeared to have begun in and been limited to the first part of the subclavian artery, and exhibited but a small amount of clot about the wire. There was no appearance of inflammation in the large space. In the first case already recorded he had had some difficulty from the kinking of the wire, but not in this second case. A tubular needle furnished with a couple of wheels for paying in the wire without touching it with the fingers would afford much aid. A rough model of this apparatus, devised by the surgical mechanician, was handed round.

Mr. HOWARD MARSH opined that the usual length of wire introduced was far too great.

Mr. T. BRYANT said that in Mr. Morris's case it was clear that the aneurysm was on the way to a cure. In Mr. Hulke's and Mr. Gould's cases there did not appear to have been any signs of healing: but in Mr. Gould's case it would seem that the large mass of wire might have been actually harmful. Still, the facts obtained by experience up to the present were not unfavourable to the operation in itself. It was almost impossible to determine with accuracy the size of an aneurysm in the throat, and so it would be difficult to say how much wire should be introduced. In the thoracic cases, perhaps, a repetition of the introduction of wire might be feasible and advisable; but this could hardly be so for abdominal aneurysms necessitating abdominal section and where the size of the aneurysm was more definable. The evidence seemed to show that the steel wire did harm in Mr. Gould's case. The use of good fishing-gut would, in his opinion, be preferable to wire. The point of steel wire must be more or less injurious, and if cut off close to the skin might become a source of irritation to the tissues. A blunt trocar might be employed with a view to pushing the cut end of the wire into the centre of the aneurysmal sac.

Mr. T. SMITH could not but be struck with the mechanical difficulties in the carrying out of the operation. A hollow needle, he agreed with Mr. Hulke, would be more suitable, and he thought that such an instrument already existed in the shape of the needle employed in cleft palate and vesico-vaginal fistula. The mill-edged wheel acted as an efficient payer-in of the wire.

Dr. PRINGLE, in reply, said that an objection to the employment of galvanism in the introduction of the wire was that the clot resulting from electrolysis is distinctly softer than ordinary clot. He would have been glad of suggestions as to any other feasible operation in cases of abdominal aneurysm, which usually encroached on the diaphragm.

Mr. HENRY MORRIS said that there would be much less tendency for the wire to assume the coil shape if a straight needle were used, such as Mr. Smith recommended. He recognised the force of Mr. Bryant's remarks, but he was not aware till now that fishing-gut could be made to coil up. Large quantities of wire would offer an obstacle to one very important element in the cure of the aneurysm—viz., retraction and contraction of the sac.

Dr. HENRY WHITE said that the aneurysm proved not to be so large as it appeared during life, and doubtless this was one reason why so much wire was introduced.

Mr. PEARCE GOULD, in reply, said that Mr. Moore, in first performing this operation, appears to have used a blunt trocar to thrust the end of the wire into the centre of the sac. The needle of Mr. Hulke or of Mr. Smith would leave the end of the wire out in the subcutaneous tissues. In future cases he would not use anything approaching the quantity of wire employed in previous cases. He shared Mr. Bryant's opinion that the evidence was against the employment of steel wire.

PATHOLOGICAL SOCIETY OF LONDON.

Alveolar Ulceration in a Child with General Tuberculosis.—Hypertrophic Goitre, with Secondary Tumours in Bones of Skull.—Tumour of Pineal Gland.—Chronic Inflammatory Disease of Uterine Appendages.—Meningeal Cerebral Hæmorrhage, with Secondary Degeneration of Spinal Cord.

AN ordinary meeting of this Society was held on the 5th inst., Sir James Paget, Bart., F.R.S., President, in the chair.

Mr. JONATHAN HUTCHINSON, jun., showed some specimens of Alveolar Ulceration and General Tuberculosis, obtained from a child aged two years, who died while under the care of Dr. Stephen Mackenzie. When twelve months old she had had measles, and subsequently became cachectic, and for a considerable time had suffered from ulcerative stomatitis, or "putrid sore mouth," which had caused several of the lower teeth to fall out and had invaded the lower lip. At the necropsy the peritoneum and abdominal viscera, especially the liver, were found to be the seat of miliary tuberculosis. The tubercles were disseminated throughout the liver, and in its capsule occurred as minute elevations one-tenth of an inch in diameter; they appeared to be of recent formation, though slight caseation had occurred in a few. It was uncertain whether any causal relation existed between the stomatitis and the tuberculosis, as the latter was a rare complication, nearly all the cases of ulcerative stomatitis in children recovering under the use of chlorate of potash or other treatment. Nor did sections of the affected gums and lip show tubercle bacilli or any tuberculous structure. The surface of the ulcers was ragged, and for a varying depth was in a necrotic condition, the structures being ill-defined and not staining well. In the lip the muscular bundles next the surface were matted together, and the striation was indistinct. Micrococci were plentiful in this layer, but the long bacilli found by Lingard and Batt in ulcerative stomatitis of calves and in a case of noma were not present. Under the necrotic layer there was considerable inflammatory cell-effusion. It was stated that ulcerative stomatitis of children could be inoculated (Bergeron), but the microscopical appearances would confirm the clinical evidence that this disease was quite distinct from noma and from the ulcerative stomatitis of calves and other young animals.—Mr. F. TREVES said that there were many arguments in favour of the suggestion that the ulcerated tongue was the seat of inoculation of tubercle.

Dr. JOSEPH COATS introduced a case of Hypertrophic Goitre with secondary tumours in the skull. The thyroid gland presented considerable enlargement of both lobes. The tissue of the enlarged gland was that of ordinary goitre—namely, greatly multiplied saccules, with occasional colloid matter in them. There were two further changes, both of which evidenced chronicity in the growth—namely, fibroid induration and calcareous infiltration. This latter change was in the indurated connective tissue, and probably in connexion with some necrosis. The goitre was first noticed sixteen years before death. There were several tumours in the skull, only one of which was visible during life, and had been observed for a year and a half; this was in the occipital region, and it formed here a pulsating swelling. This tumour replaced the bone of the skull over an area an inch and three-quarters in diameter, and projected both outwards and inwards, pushing the torcular herophili before it. Another projected chiefly inwards, and was adherent to the dura mater. All the tumours apparently originated in the diploë of the skull. Their structure was identical with that of the goitre, consisting of innumerable small saccules lined with epithelium, and occasionally with colloid contents. Dr. Coats referred to Cohnheim's case, which was of a similar nature; and he also quoted a case of Wölfler's in which a tumour, removed during life by Billroth from over the eye, was found to have typically the structure of the ordinary goitre. This patient was also affected with goitre.—Mr. R. J. GODLEE had examined Mr. Morris's specimen of pulsating tumours of the left parietal bone associated with other similar tumours of the right clavicle and both femora recorded in the Pathological Transactions, vol. xxxi. There was also a goitre in this case, and the tumour of the skull showed thyroid-like tissue.—Mr. G. R. TURNER mentioned a case of goitre associated with secondary growths in the lung reported in the Pathological Society's Transactions.—In reply to Sir James Paget, Dr. COATS said that Wölfler had figured many tumours of the thyroid: carcinomata, sarcomata, and the ordinary forms of goitre. In some cases of advanced goitre the formation of colloid was often more pronounced, leading to the formation of large cysts. In reply to Mr. Godlee, he said that he had not detected sarcomatous tissue in cases of ordinary goitre.

Dr. JOSEPH COATS also showed a large Tumour of the Pineal Gland. The tumour, which consisted of two rounded lobulated masses, measured about three inches transversely, and two inches from before backwards. It was surrounded by a capsule and loosely attached, except at one point which corresponded to the situation of the pineal gland. In its growth it had dislocated and disturbed the neighbouring structures, the parts affected being there normally in relation to the pineal gland. The corpus callosum, choroid plexus, and velum interpositum were pushed upwards, the corpus callosum being greatly softened. The corpora quadrigemina were pushed backwards and upwards, and the thalami optici outwards and forwards, these parts being greatly flattened. The bulk of the tumour was in the third ventricle, but it had also extended somewhat into the aqueduct and fourth ventricle. The structure of the tumour was very peculiar—namely, a basis of sarcomatous structure, with pieces of cartilage and epithelial or glandular structures embedded in it. The sarcomatous cells were chiefly spindle-shaped, and some of them in the shape of the nuclei and general arrangement suggested smooth muscle. The cartilage was hyaline, with the cells unusually abundant. The gland structures were in the form of saccules or ducts lined with epithelium, usually cylindrical. The saccules were occasionally dilated, but did not form true cysts. Dr. Coats was disposed to call the tumour, from its structure, an adenoid chondroid sarcoma. He referred to four other cases of similar forms of tumour, recorded by Weigert, Falkson, Ziegler, and Turner, in all of which the structure was complex, with epithelial or glandular structures, and in three of the cases with cartilage. The observations of Baldwin Spencer on the pineal eye were referred to as indicating the original complex structure of the pineal gland, and it was stated that the embryonic structure indicated that the pineal gland was an epithelial body.

Mr. LAWSON TAIT read a paper and exhibited fifty-eight specimens, removed during the year 1886, illustrating the Pathology of Chronic Inflammatory Disease of the Uterine Appendages. Although Ruysch had recognised these diseases, their frequency and serious nature had only been allowed during the last ten years. The frequency was somewhat indicated by the fact that Mr. Lawson Tait had operated sixty-three times, with but one death, during the past year. All the patients had suffered for years. Cases were grouped under four headings: (1) simply catarrhal; (2) due to exanthematic disease at puberty; (3) gonorrhœal; (4) inflammatory mischief in the pelvis in the post-puerperal condition—i.e., after a miscarriage or a full term labour. A fifth was added by Mr. Tait: cases in which the only explanation was the existence of an infantile condition of the uterus due to arrested development. Retroversion, with complete fixation and enlargement of the appendages, was general. The preponderating influence of the third and fourth causes was at once indicated by the fact that out of the sixty-three cases there were only ten unmarried women. Of these ten single women, there can be no doubt that in at least three of the instances the origin was gonorrhœal. In two of the single women there had been pregnancies, and these were in all probability the source of the diseased appendages. In one case prolonged efforts had been made to cure anteflexion by means of intra-uterine pessaries, and this doubtless resulted in the double pyosalpinx. Of the four remaining cases in single women, two were probably due to scarlet fever. In the fifty-three women who were married, the average age was a little over thirty-three years. Of these, twenty-three had never been pregnant, and they had been married on the average ten years. Of the remaining thirty cases, sixteen had been pregnant once, the pregnancy occurring immediately after marriage, and being associated in every instance with the history of subsequent pelvic trouble. The average interval in these cases between the pregnancy and the time of the operation was eleven years. Only fourteen of the patients had more than one child, and the average period between the last pregnancy and the time of the operation was six years. These facts were enough of them-

Digitized by Google

selves to show how completely sterility is produced by chronic inflammatory disease of the uterine appendages. In by far the greater majority of the specimens the occlusion has taken place by the trumpet getting glued on to the ovary. The frequency of this occurrence substantiates, to some extent at least, the tradition that the infundibulum gets fastened on to the ovary temporarily at some time or other in connexion with the process of ovulation. Formerly the author thought he should be able to prove that this relation did actually occur, but he has never been able to make himself certain of it. In some cases the trumpet is found to have closed its tentacles, like a polyp, and to have had them coalesced in that position, leaving the ovary free. In the group of twenty-three women who had been married for an average period of ten years and had never been pregnant, there can be no doubt, from the clinical histories of nearly a third of them, that the disease arose from old latent gonorrhœas or gleets in their husbands excited into activity by the indulgence of early married life. In rather more than a third the author believed the disease originated in the exanthematic diseases of girlhood, most especially scarlet fever; and in the others no clue to causation could be obtained. In the second group of fifteen women in whom there had been one pregnancy within a short time of marriage, we assume, of course, that at the time of marriage their productive machinery was intact. In all but two of these cases, the story of pelvic peritonitis following their only labour placed them clearly in the group in which puerperal mischief has to be regarded as the cause. In the exceptional two, the author believed that he failed to get the history rather from the stupidity of the patients than from an absence of the facts. A third group was readily formed of fourteen women whose fecundity was not limited to one child. In this group were found the most acute and severe cases. At least eight of these women suffered from subacute or even acute gonorrhœal salpingitis of comparatively recent origin, the average time which had elapsed between the last pregnancy and the operation being three years. On the other hand, in the six other women in this group in whom the author could get no such history (or doubtfully in two of them), fourteen years had on the average elapsed between their last confinement and the date of the operation. These facts have a striking pathological significance. In the acute or early stage the appendages are intensely congested and swollen, and are very friable. In fact, it is a matter of difficulty to remove them entire. In the old-standing cases the organs are contracted and atrophied, and few if any traces of normal follicles can be discovered in the cirrhotic and densely adherent ovaries. At this stage the tubes generally contain very little fluid, and their contents are sometimes cheesy. They may be purulent on one side and serous on the other. Certain it is that neither the quantity of this fluid nor its pathological characters bear any definite relation to the sufferings of the patient. The pain endured in these cases is related to the adhesion of the organs, and to nothing else. The author had been much interested lately in reading a paper by Dr. Säuger of Leipsic, in which he determines varieties of tubal disease by the application of the germ theory, giving to the varieties names based on the kind of lowly organisms found in the contents of the tubes. Thus when a gonococcus is found he speaks of salpingitis gonorrhoica; and when he finds actinomycetes he calls it S. actinomycotica. If it is characterised by Koch's bacillus tuberculosis, he records it as S. tuberculosa. This kind of distinction seems to the author to have much attraction for the speculative mind, and but little for the practical pathologist. It has, besides, the initial difficulty that it is based on a doctrine which has yet to show that it is not mistaking the phenomena of decomposition for those of disease. Since reading Säuger's paper the author had given some little attention to the fluid contents of the tubes, and he had already found evidence that if the distinction of varieties were to be based upon the characters of the lowly organisms present in the fluid, the probability was that their extension would be indefinite and easily multiplied. In conclusion, the author submitted a post-mortem preparation for which he was indebted to the kindness of Dr. Littlejohn of Edinburgh; it was an example of the simple hydrosalpinx without adhesions, and so far as its clinical history could be ascertained the patient suffered little or nothing, but was perfectly sterile. Also an admirable drawing made by Dr. Kellie, used in his lectures nearly a century ago, which showed the condition of occlusion and distension of the tube most beautifully. Also some drawings of Dr. Price of Philadelphia, showing the ovaries and tubes in a condition of acute gonorrhœal inflammation.

Mr. ALBAN DORAN showed specimens illustrating the Development of Tubo-ovarian Cysts as a result of Inflammation of the Uterine Appendages. He exhibited a pair of appendages which had recently been removed by Dr. Bantock from a woman aged twenty-three, subject to chronic pelvic pains and other severe symptoms. The right tube and ovary had undergone complete cystic degeneration, so as to form a cyst with one cavity. The left tube was dilated; a cyst had formed in that part of the ovary most distant from the dilated tube. Mr. Doran showed a series of diseased appendages from the museum of the College of Surgeons, where every stage of the process of conversion of chronic inflamed appendages into tubo-ovarian cysts was demonstrated. On the other hand, he had never succeeded in finding a tubo-ovarian cyst developed as a part of the process of development of the common ovarian cystic tumour, a non-inflammatory disease. Hence he believed that tubo-ovarian cysts almost invariably represented an atrophic inflammatory condition.—Dr. HADDEN referred to the frequency of tubercular disease of the Fallopian tubes. Why was the outer half of the tube more dilated than the inner?—Dr. ANGEL MONEY said that tubercular disease of the abdomen in children frequently got well. He had seen genuine tubercular pyosalpinx in children.—Dr. JOSEPH COATS also thought that tubercular disease was also a common cause of disease of the Fallopian tubes. He had seen it nearly always in tubercular peritonitis. It might also occur alone.—Dr. GRIFFITH remarked that he had been lately engaged in investigating the subject of tubo-ovarian cysts, the literature of which was very scanty, and a paper by him on the subject was now in the hands of the Obstetrical Society. His investigation led him to the conclusion that there were two kinds in addition to that described by Mr. Doran, the rarest of which was formed by the union and communication of a dilated tube with one loculus of the common multilocular cyst. Another variety which seemed to be very uncommon was that first described by Adolphe Richard, consisting of a dilated tube adherent to and communicating with a thin-walled unilocular cyst of the ovary, the size of a child's head, or smaller, producing a tumour having the shape of a retort, and containing thin watery fluid, more resembling the contents of a broad ligament than an ovarian cyst. These were discovered in young women in whom the history and evidence of past inflammation were very scanty. Dr. Griffith believed that the specimens brought forward by Mr. Lawson Tait would well repay careful examination. The clinical history and histology of diseases of the tubes had yet to be investigated.—Mr. LAWSON TAIT said that he treated only of cases operated on by him during the past year. He had seen but one case of tubercular pyosalpinx, on which he operated, and the patient recovered, which made him doubt the tubercular nature. He agreed with Mr. Doran's view of the mode of formation of tubo-ovarian cysts.—Mr. ALBAN DORAN, in reply to Dr. Griffith, stated that "tubo-ovarian cyst" was a matter of definition. Many of the observers to whom Dr. Griffith referred appeared to apply the term solely to cases where the tube had communicated with a true ovarian cyst.

Dr. HALE WHITE showed a specimen of Old Meningeal Hæmorrhage, with Cerebral Softening and Secondary Degeneration, which was taken from a patient who died owing to the effects of a femoral hernia. From the history it would appear that the meningeal hæmorrhage took place eighteen months previously. At the necropsy ante-mortem clotting in the sinuses was discovered. On the left side, over the ascending parietal and frontals, and the back part of the first, second, and third frontal convolutions, there was some soft yellowish-white material, evidently old blood clot. The grey matter over the area mentioned had quite disappeared; the white substance immediately underneath was a little altered; no distinct degeneration could be seen in the pons or internal capsule, but the pyramidal tract in the medulla, and both the crossed and direct pyramidal tracts in the cord, were distinctly degenerated, being grey, translucent, and hard-looking. The lateral column was smaller on the affected side than the healthy. The microscope showed the sclerotic changes to be the same as those usually described.

The following card specimens were shown:—Mr. E. H. Fenwick: Tumour of the Bladder. Dr. Turner: Congenital Stricture of the Jejunum. Dr. Hale White: (1) Peripheral

Digitized by Google

Neuritis; (2) Dilatation of the Ureter and Hydronephrosis of one side, secondary to stricture of urethra. Mr. D'Arcy Power: Sequel to case of Endosteal Sarcoma. Dr. Thin for Dr. B. Bake: Drawings of Bacillus of Leprosy. Dr. Edmunds: Carcinoma Myxomatodes. Mr. F. W. Clark: Acute Pericarditis. Mr. Hudson: Colloid Cancer of Stomach. Dr. Allchin: Perforating Ulcer of Duodenum. Mr. Shattock: (1) Congenital Dislocation of Hair; (2) Two specimens of Osteomalacia, showing metaplasia of osseous into fibrous tissue.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, April 6th, Dr. John Williams, President, in the chair.

Uterus Bicorpor.—Dr. HANDFIELD JONES showed a uterus having one cervix and two bodies. The left horn had been recently pregnant, while the right one was enlarged, either from sympathetic hypertrophy or owing to subinvolution after previous pregnancies of the right horn. The woman had died of puerperal eclampsia after her fifth confinement. Douglas's pouch was bipartite.

Anterior Parametritis and Perimetritis.—Dr. W. S. GRIFFITH showed two characteristic specimens of these conditions with drawings.

The Mechanism of the Third Stage of Labour.—This paper, by Dr. CHAMPNEYS, was the second of a series, and dealt with the Expulsion of the Placenta. The author reviewed the literature of the subject, including the observations of Lemser, Salin, Duncan, Schultze, Ribemont, and Ahlfeld. He showed that the question centres round the opposing views of Schultze (which are corollaries of those of Baudelocque) and those of Duncan. The difference is as to the presence or absence of hæmorrhage as part of the normal procedure, including the inversion of the placenta, this being described by Schultze and denied by Duncan. Direct observations are very few and are contradictory. The author gave his own observations of 70 cases, carefully observed and tabulated, as regards the manner of the expulsion of the placenta and the blood lost in each case. The fœtal surface presented in 64, the maternal in 2 (in both of which the cord had probably been pulled upon), the amnion in 4. Adding his results to those of Pinard and Ribemont, the author found that the fœtal surface presented in 127, the fœtal edge in 27, the maternal surface in 5. The presenting point was nearer the lower edge of the placenta in 65, nearer the upper edge in 1, midway in 2, no note of its position in 2. The lower edge, or amnion below the lower edge, presented in 16. In the great majority of cases a point within two inches of the edge presented, but on the fœtal surface. There was a complete absence of fundal attachments. It was found that the presenting part varies in its position with the position of the placenta. The higher the placenta the higher the presenting point, and *vice versâ*. The average loss of blood before the expulsion of the placenta was six ounces, in the membranes or with the placenta six ounces, making an average of twelve ounces for each labour, not including post-partum hæmorrhages. The author believes that a moderate loss of blood is a normal phenomenon of the third stage of labour; the third stage of labour is not either actually or nearly a bloodless operation. He concludes finally that—1. Some measureable hæmorrhage is a normal constituent of the phenomena of the third stage of labour. 2. The placenta presents in the great majority of cases by a point on the amniotic surface. 3. The presenting point is almost invariably near the lower edge of the placenta. 4. The position of the presenting point varies with the position of the placenta. 5. The "inversion" of the placenta is not due in the great majority of cases to traction on the cord, but is part of the natural mechanism. These observations, therefore, accord in essentials with those of Schultze, though his diagrams are greatly exaggerated. These observations bear on the opinion previously expressed as to the causes and mode of *separation* of the placenta. Therefore—1. It is probable that, in addition to reduction of the placental site, some escape of blood plays a part in the ordinary mechanism of placental detachment. 2. The slight inversion of the placenta, which does take place, is probably due to this cause. 3. The effusion of blood is not, in ordinary cases, sufficient to form a large mass bulging into a large uterine cavity behind the placenta.—Dr. MATTHEWS DUNCAN congratulated the Society on the elaborate paper just read, not only on account of its intrinsic value, but also because of its affording the Society an opportunity of contributing to the progress of the greatest obstetric work of the century. In the history of midwifery there were only three works of the very highest class as yet achieved. The first in scientific order of progress was done in the eighteenth century by W. Hunter, whose plates on the "Anatomy of Pregnancy" were its crown. The second was a work mainly of this century, and was known as the "Mechanism of Parturition," and with it were connected many names, especially those of Solayrer and of Naegele. The third was still incomplete, the greatest, most difficult and most glorious of all, a work of the nineteenth century, the "Anatomy of Labour." In this country no name was so great in the anatomy of labour as that of Barbour, and he was actively engaged in it at this moment. No contribution to it had come from London, and the papers of Dr. Champneys he hailed as worthily bringing a part of it before this Society. The anatomy of labour made no progress till the introduction of homalographic sections of frozen bodies. No such sections had been done in London, and nowhere had such sections been made in the third stage of labour. The work of Dr. Champneys was mainly physiological, and should come after the completion of the anatomy of the third stage, for the subject of his work would not be settled till the anatomy was finished. Failing to find bodies for the sectional anatomy of the third stage, obstetricians had examined the uteri of the operation of Porro. This was an imperfect substitute for frozen sections, and might be very misleading. The Porro uterus examined by Barbour showed that the placental area might be contracted to a diameter of four inches without separation, and the absence in these cases of hæmatoma was hostile to the theory of separation by utero-placental hæmorrhage, but it did not disprove it. Absence of separation, with contraction to an area of four inches in diameter, seemed to astonish many, and to favour the detrusion theory of separation. Dr. M. Duncan always imagined a much greater contraction as necessary for separation. He referred to his own paper of 1871, which was now a matter of "ancient history." Yet, admitting its imperfections, he was still an unbeliever in the presence of hæmatoma in a natural separation in a theoretically natural case, and he continued to hold that the cake descended edgewise through the cervix, and a reference to Dr. Champneys' table, columns A and B, confirmed this. The old detrusion theory of separation he had found difficult to make intelligible. He could not understand the production of detrusion till after separation. He could not imagine detrusion pushing off the lowest flap (as in the Porro case exhibited by Dr. Galabin) without pushing off all above it.—Dr. GALABIN understood that the author had not come to a decided opinion whether the separation of the placenta was from the periphery to the centre or *vice versâ*. Dr. Galabin thought this depended on the cause of separation. If the cause were from shrinking of the placental site, separation must be from the periphery inwards. If hæmorrhage were the cause, it must occur away from the margin, and could only effect a separation from the centre towards the periphery. Even if it were admitted that an effusion of blood is normally present, it does not follow that the hæmorrhage is a cause rather than a consequence of detachment.—Dr. Galabin thought that the Porro uterus was in favour of shrinking of the placental site, with possibly detrusion as a cause of detachment, and not hæmorrhage. Detrusion, acting as a supplementary cause to shrinking would cause detachment of the *lower* margin first. As regards the mechanism of expulsion, he thought it depended on the management of the third stage of labour. In Salin's cases the placenta presented at the os by its lower margin, and there was no inversion. In Dr. Champneys' cases there was partial inversion. In Lemser's cases the upper edge usually presented. The probable reason was that the management of Salin's cases promoted the best uterine contraction; that of Lemser's the greatest relaxation; that of Champneys' an intermediate condition. Dr. Galabin did not think that leaving the uterus unsupported with the patient on her side and the fundus dependent would give the most ideally natural mechanism.—Dr. HANDFIELD JONES thought that an ideally healthy labour was bloodless as regards the separation of the placenta, though there might be variable amounts flow afterwards.—Dr. BOXALL thought there were causes for separation of the placenta not mentioned in Dr. Champneys' papers. After

Digitized by Google

the birth of the child the conditions were profoundly altered: the flow of blood from the fœtal portion of the placenta to the lungs ceasing, the thin lamina of maternal tissue is deprived of support towards the cavity of the uterus. The position in which the placenta is implanted on the uterus Dr. Champneys had shown to be important, and this again was indissolubly connected with the separation of the membranes. As long as the membranes at the edge of the placenta remain adherent to the uterine wall, inversion of the placenta is maintained. If any portion of the attachment gives way, the adjacent margin of placenta, being no longer supported, becomes the most dependent part, and the subplacental hæmatoma finds an exit of escape, and the lower the implantation of the placenta the more easily will this happen. There were other causes that altered the process of detachment, as pulling on the cord and abnormal adhesion. Dr. Boxall explained a series of experiments which he had made to determine the placental presentation by means of staining. He also confirmed Dr. Champneys' remarks on the rarity of fundal attachment of the placenta. He had found the fundus overlapped (to the extent of an inch and three-quarters) only once. Out of one hundred cases, he should say that the placenta would occupy the upper zone in twenty-one, the middle zone in seventy-seven, and the lower zone in two.—Dr. GANDY wished to know if kneading of the uterus was made use of to expel the placenta.—Dr. W. S. GRIFFITH thought there was some analogy between the detachment of the membranes in membranous dysmenorrhœa and the detachment of the placenta.—Dr. CHAMPNEYS replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AN ordinary meeting was held on Feb. 4th, Dr. S. C. Smith, President, in the chair.

Method of Ligaturing an Intercostal Artery.—Mr. CLIFFORD TURNER described a method by which a special curved needle was passed below the vessel and upwards over the rib, the ligature being tied over a pad. He described various modifications of the process, according to the position of the wound and the age of the patient.

Resection of Bowel for Intussusception.—Mr. LAWFORD KNAGGS described a case of laparotomy for intussusception in a young child, and showed the removed portions of gut. The patient died in a few hours. In a review of the treatment to be adopted in such cases, he recommended the cautious use of inflation, and should this be unsuccessful, immediate laparotomy to be had recourse to.—Mr. PRIDGIN TEALE, who had seen the case, said he thought abdominal section should be more frequently done in these cases. He described several cases—one in a man of eighty-six, where he had removed gangrenous bowel and sutured the ends of the gut together. The patient lived six days, dying of exhaustion, the obstruction having been relieved.—Mr. MCGILL had decided that in the next case under his care he would make a longitudinal incision over the distended bowel, withdraw and incise the invaginated portion, stitching the opening to the skin, making a fæcal fistula which could be dealt with afterwards. He thought that excision of gangrenous bowel and suture must nearly always be fatal.

Hemianopsia.—Dr. WARDROP GRIFFITH described, with the aid of diagrams, the several varieties of hemianopsia and their probable anatomical relations, both with regard to lesions of the optic tract and internal capsules and the cortex of the brain. He related several cases where a permanent hemianopsia appeared to indicate grave organic disease.

Pathological Specimens.—Dr. CHADWICK showed some Living and Preserved Specimens of the Filaria Sanguinis Hominis, from a case under the care of Dr. Stephen Mackenzie.—Mr. MAYO ROBSON showed (1) a Foot with extensive Sarcomatous Disease of bone; (2) a Hydrocele in the Sac of an old Hernia, the neck being sealed by a piece of omentum.—Mr. BACON showed a Larynx from a case of poisoning with Carbolic Acid, much eroded by the action of the irritant.

A meeting was held on March 4th, Dr. Eddison in the chair.

Raynaud's Disease.—Dr. ERNEST JACOB described two cases of this disease lately under his care, one of the patients being exhibited. Case 1: A lad of twenty from his ninth to his twelfth year used to handle a wet chain in a colliery. His hands ever since had been always cold. The fingers were stiff, blue, and cold, and subject to acute pain. There was no arterial disease, and his general health was good. He improved under the use of iron internally and a stimulating liniment to the hands. Galvanism was tried in vain. Case 2: A laundress, aged fifty-seven, began to suffer from coldness and numbness of the hands thirty years ago, with severe pain of lancinating character. This recurred whenever her hands were at all exposed to cold. Two years ago she became worse; the fingers became black and discoloured, remaining so for two or three weeks, when they would become red, and the nail drop off, being succeeded by a new nail. Gradually gangrene supervened, and the tips of the first and second fingers of the left hand had disappeared. On the right hand the first finger had lost the two terminal phalanges and the little finger the third. The general health was not good, and though the arteries seemed healthy, there was an aortic regurgitant murmur. She had since been an in-patient in the infirmary under the care of Mr. McGill, the gangrene having still further progressed. The history of the disease was referred to, its pathology as a vice of arterial innervation, and its clinical connexion with the "night palsy" described by Dr. Weir Mitchell, paroxysmal hæmatinuria, and different varieties of vasomotor spasm were alluded to.

Treatment of Mastitis.—Mr. C. J. WRIGHT described a number of cases of painful lactation or inflamed breasts, in which he had found firm pressure by a bandage or towel afford great relief to the pain and other symptoms. Abscesses were to be opened antiseptically, and poulticing to be used as little as possible.—Mr. A. ROBERTS spoke of the advantages of fomentation with solution of ammonium carbonate.—Dr. PURDY had been disappointed at the results both of pressure and ammonium carbonate fomentation.—Mr. J. W. TEALE thought belladonna plaster useful mostly through the support it gave; he spoke highly of pressure, but generally gave a morphia injection as well.

Dangers of Cocaine.—Mr. A. ROBERTS described a case where he amputated the breast after injection of cocaine, sixty minims of a 6 per cent. solution being used. The patient felt no pain, but became blind, talking rapidly and somewhat incoherently. The blindness lasted four hours, but she recovered completely.—Dr. CLIFFORD ALLBUTT said he had experienced after the use of cocaine symptoms which had been recorded by others—viz, dreams in which writhing worms formed the principal object.—Mr. HEWETSON said that in using cocaine for ophthalmic purposes corneal opacities were apt to be left if a mercurial antiseptic were used.—Mr. OAKELEY had seen bad effects from strong solutions, but found that the desired effect could be produced with a maximum of thirty minims of a 4 per cent. solution. He had found amylic nitrite very useful as an antidote.—Mr. MAYO ROBSON had had two cases only out of a large number which had caused him any anxiety—viz., one in which severe syncope followed an operation for circumcision, and another where aphasia, lasting four hours, followed the removal of a nasal polypus.

Mr. LAWFORD KNAGGS showed a patient on whom Abdominal Section had been performed. The case was found to be one of tubercular peritonitis, and the patient had completely recovered.

Last days of a case of Graves' Disease.—Dr. CLIFFORD ALLBUTT was called to a case of a lady almost moribund, with symptoms of failing heart. There was dropsy, congestion of lungs, orthopnœa, &c. The heart's action was quick, but there was no detectable valvular lesion, the action being most like that noticed in a case of Graves' disease. Inquiry showed that there had been both enlargement of the thyroid and great exophthalmos in the past, but these had disappeared two years before.

Syphilitic Coma.—Dr. ALLBUTT referred to a paper by Dr. Althaus on syphilitic coma, and described the case of a lady of fifty, who had had repeated attacks (seven or eight) of coma, lasting from two to five days, on two or three occasions accompanied by slight hemiplegia, but with perfect recovery. He regarded this as due to syphilis, of which there was good evidence in this case, and potassium iodide had been of great use in the treatment.

Acute Atrophy of Liver.—Dr. HUTCHINSON showed a liver with microscopical sections. There was jaundice for nine days before death, and there was some cirrhotic change, as well as the indications of atrophy.

Digitized by Google

Mr. LITTLEWOOD showed fresh cut sections of an Alveolar Sarcoma from the back of the Sacrum.

Dr. JACOB showed microscopic sections of a "Duct" Cancer of the Breast, from a case under the care of Mr. T. P. Teale.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE sixth meeting of the session was held in the Faculty Hall, St. Vincent-street, on March 23rd.

Dr. MURDOCH CAMERON showed a Cervix Uteri amputated by Prof. Leishman for elongation in a nullipara, and advocated the use of the galvanic écraseur in such cases.

Mr. J. S. NAIRNE exhibited two simple forms of Wire Clamp, and Dr. SMITH exhibited Cones of Cocaine and Boric Acid, recommended by Dr. E. Head Moore for use in primiparæ and cases of rigid os.

The President, Dr. Sloan, then showed the Spleen and Uterus and Appendages of a primiparæ, aged twenty-two, who had died in the Maternity on the twenty-second day post partum, after a somewhat unusual illness. The specimens had been kept in spirit. The spleen had been adherent, and on removing it a quantity of grumous material had escaped from a cavity in the upper extremity. In this region it separated in two parts, joined by a mass of tough fibrinous material, its surface being coated with lymph. Otherwise the tissue was friable, and Dr. Dalziel had reckoned that the rupture indicated by these appearances must have taken place from three to four weeks prior to death. There was no appearance of pus in or around the organ. The uterus measured four inches and a half in length, and with its appendages looked quite normal, being covered with smooth and glistening peritoneum, and showing no trace of pus or putrefaction. There were no appearances elsewhere of septicæmia or pyæmia. Though the urine was one-third albuminous, the kidneys were found healthy post mortem.

Reviews and Notices of Books.

Recent Essays by various Authors on Bacteria in relation to Disease. Selected and edited by W. WATSON CHEYNE, M.B., F.R.C.S. London: New Sydenham Society. 1886.

Les Bactéries, et leur Rôle dans l'Anatomie et l'Histologie Pathologiques des Maladies Infectieuses. Par A. V. CORNIL et V. BABES. Deuxième Édition. Paris: Felix Alcan. 1886.

THE New Sydenham Society, which has done not a little to familiarise the English practitioner with the best writings of foreign scientists, has seldom accomplished better work than in undertaking the collection of monographs included in the volume edited by Mr. Watson Cheyne, in which, after a very interesting and suggestive introduction, we have, gathered from various sources and translated by capable hands, some of the best bacteriological work of the day. It is a great advantage to have access to such notable essays as that of Koch on Tuberculosis, Fehleisen on Erysipelas, Friedländer on Pneumonia, and Israel on Actinomycosis; and these only form a small portion of the rich contents of the volume. Dr. Koch's paper on the Investigation of Pathogenic Organisms, translated by Mr. Horsley, fitly introduces the volume. It is characterised by the clear and definite phraseology which has done so much to add to the charm of its author's expositions. His far-famed monograph on the Etiology of Tuberculosis, for the translation of which Mr. Stanley Boyd is responsible, comes next. No one can read this without becoming convinced of the truth of a discovery which aptly came to crown the labours of pathologists upon the nature of tubercle. "Seldom in the course of my life," wrote Cohnheim, "have I received such glad tidings," when the news of Koch's discovery of the bacillus tuberculosis reached him. On the additional light which such a discovery has shed upon specific diseases and inflammations there is no need now to dwell. One of the most interesting monographs—to English readers—is that by Dr. Gaffky upon the Etiology of Enteric Fever, which is translated by Dr. J. J. Pringle. Gaffky's researches were confirmatory of Eberth's discovery of a special bacillus in the intestinal lesions as well as in other organs. This bacillus is about one-third the diameter of a red corpuscle in length and three times as broad as long, and is distinguished from other bacteria by its power of spontaneous movement, its slight affinity for aniline dyes, the non-liquefaction of gelatine inoculated with it, the characteristic colonies it forms when grown on potato or solid blood-serum, and the spore formation at the extremities of the bacillus. The failure to produce inoculation of animals does not tell so strongly against its pathogenic character as might be supposed; and, as pointed out by Gaffky, there is as much reason for regarding it as the specific agent as there is in the case of the spirochœte of relapsing fever or the bacillus of leprosy. Fehleisen's memoir on Erysipelas is translated by Dr. Leslie Ogilvie. It is admirable for the clearness of its reasoning, and for the light it sheds upon the nature of erysipelas, as distinguished from other forms of dermatitis and cellulitis. The specific nature of the micrococcus discovered by Fehleisen is attested by the crucial experiments on human subjects, who were inoculated with cultures for the therapeutic purpose of causing the absorption of new growths through the action of erysipelas. Friedländer's paper on the Micrococci of Acute Pneumonia is translated by Edgar Thurston. The subject is one which has been further investigated since this discovery was announced, and the precise significance of the pneumonococcus is still *sub judice;* yet there can be little doubt as to the characteristic morphology and mode of growth of this remarkable microbe. Amongst other papers included in this collection we are glad to see that of Dr. Koch upon the Etiology of Cholera (translated by Dr. G. Laycock). The comma bacillus may or may not be the cause of cholera, but in the history of that disease the researches conducted by Koch which resulted in the discovery of that micro-organism will always hold a prominent place. Mr. Watson Cheyne supplies valuable abstracts and translations of writings upon Traumatic Infective Diseases, notably those of Rosenbach, in which the determination of the part played by the two varieties of staphylococcus pyogenes was first clearly established. Dr. Loeffler's paper on Diphtheria in Man—of which an abstract is furnished by Dr. T. Whiteside Hime,—although suggestive and interesting, proves how difficult it is to arrive at a definite conclusion upon the etiology of this disease. In some cases the specific organism seems to be a streptococcus, in others a bacillus; whilst perhaps the most important idea gained from the study is that primarily the disease is a local one. Dr. Hime also supplies an abstract of Israel's well-known paper on Actinomycosis in Man—another of the real additions to pathological knowledge for which science is indebted to the bacteriologist. Other papers in the volume are those by Neisser on the Bacilli of Leprosy, translated by Dr. Thin; by Loeffler and Schütz on the Bacillus of Glanders, translated by Dr. G. Ogilvie; several papers by Koch and others on Disinfection, abstracted by Dr. Whitelegge; and last in order, but not in importance, a very valuable abstract by Dr. Dawson Williams of the work done, largely by Pasteur and his pupils, upon the Attenuation of Virus and Protective Inoculation. The volume, as we have said, is of great value, and it only remains to congratulate the various contributors on the manner in which they have performed their several tasks.

It says much for the prevalent pursuit of bacteriology that the standard work of Cornil and Babes should have attained to the honour of a second edition within twelve months of its first appearance. It is evidence also of the high value set upon the work itself, for undoubtedly it deserves to rank as the leading treatise on the subject. Its

Digitized by Google

authors have a great reputation, and they have amply maintained it in this work, which contains not only their personal researches, but a carefully digested account of all that has been done in this wide field. So rapidly is progress being made that, as they truly remark, books on bacteriology soon fall out of date, and certainly they seem to have spared no pains to keep their volume up to present knowledge. Although so much has been accomplished, MM. Cornil and Babes point out how much more there is yet to do, both in the direction of the discovery of micro-organisms in certain specific diseases, and in the verification of discoveries alleged to have been made in others. Bacterial research has gone far to banish the doctrine of the spontaneous origin of specific disease, and to establish the specific nature of other affections; whilst the more knowledge that is gained concerning the nature and mode of action of these minute parasites, the more is the field open for successful prophylaxis. The work is divided into three parts, the first containing chapters on the methods of investigation and experiment, as well as a description of the varieties of bacteria, and the doctrine of ptomaines. The second part is devoted to acute infectious diseases attributable to the intervention of bacterial organisms, those limited to animals being first discussed; then traumatic infective diseases, pneumonia, diphtheria, typhoid fever, relapsing fever, intermittent fever, cholera, anthrax, variola, scarlatina, &c. The third part treats of chronic bacterial diseases, such as rhinoscleroma, tuberculosis, leprosy, and syphilis, a description of M. Pasteur's labours in hydrophobia being appended. This mere enumeration can, however, give no adequate notion of the special excellence of the work. The pathology of each disease, and particularly its pathological histology, is amply discussed side by side with the description of the specific microbe to which it is attributed: and all that can be done by a liberal use of illustrations, mostly coloured, is given. We must be content here with simply welcoming the work, and expressing a very strong opinion of its value.

Health at School, considered in its Mental, Moral, and Physical Aspects. By CLEMENT DUKES, M.D. Lond. Pp. 324. London: Cassell and Co. 1887.

THIS book, which is an expansion of the article on Health at School contributed by the author to Mr. M. Morris's "Book of Health," appears to us to supply a want which has been long felt; for although there have been many works on different matters connected with school health, we do not know of any one which has gone so exhaustively into the whole subject. It contains matter which deserves the careful study of parents, head masters, house masters, and form masters alike. In the selection by parents of a suitable school for their boys, its healthy situation, its sanitary condition, its adaptation to the capability of the boy, the character and traditions of the school, the qualities of the head master, and still more of the house master under whose care they are to be placed, are all matters demanding the most serious consideration. But parents must not forget how much depends upon themselves in the formation of the character of their boys before they attain the age at which it is usual to send them to school. It is their special duty to see that habits of truthfulness, honour, and uprightness are formed in the earliest years—really before school-days commence,—as it is almost impossible to form such habits afterwards. The sanitary construction of the school and of the master's boarding-houses is clearly set out and strongly dwelt upon; the means of preserving the health of the boys by attention to their diet, their school work, and their play, are all matters which require the constant supervision of the masters. On the subject of overwork, which has of late been much discussed, Dr. Dukes' remarks are excellent. He points out how clearly the amount of work which can be safely done depends, in a great measure, on collateral circumstances—the age and health of the boy, the conditions under which he works, as regards food, sanitation, exercise, and a judicious arrangement of the work; while he does not forget to inculcate the necessity for care and judgment to prevent shamming, and to avoid attributing to overwork conditions which are due to other causes. "Thus, headaches are sometimes caused by working or sleeping in impure or prebreathed air; often through a failure in sight, which could be, and should be, rectified at once by appropriate spectacles; and most frequently of all, these headaches are toxæmic, from imperfect action of some of the secretions, such as constipation, but especially would I mention albuminuria. On several occasions I have seen boys who had all the symptoms of overwork, and from whom no further work could be obtained, cured of all head symptoms, as soon as the cause was discovered, by an aperient and a milk diet only for twenty-four hours."

The chapter on Illness is one of great importance, as it discusses the medical arrangements for the treatment of disease and the isolation of infectious, and thorough quarantine of doubtful, cases until their exact nature has been determined. The steps which ought to be taken to prevent, as far as possible, the introduction of disease into school, and its spread if a case unfortunately should occur, and the measures incumbent on the school authorities to prevent infectious disease being carried home from school are very well laid down, and, if adopted, cannot fail to exercise a most beneficial influence in preventing the spread of disease, which is only too common from neglect of these precautions. Dr. Dukes gives tables of the period of incubation of various infectious diseases, and the probable duration of infection where efficient disinfection is in force and where it is not in force. These will prove useful to parents and masters in carrying out a system of protection for the boys under their care. He has also suggested forms of certificates to be used in cases of boys coming from homes in which there has been infectious disease, and of those returning to their homes from school under similar circumstances. We commend the study of this chapter to all who have any control over or are responsible for the welfare of schoolboys.

The book has been evidently prepared with great care, and shows a practical knowledge on the part of the author of the subjects of which he treats. We cannot recommend it too highly to the head masters and governing bodies of public schools, and to all who are interested in the welfare of the rising generation. Should it reach a second edition, we trust that the author will not omit to add to its practical value by preparing a copious index, so as to facilitate reference to any of the special points in it on which information may be desired.

OUR LIBRARY TABLE.

Some Phases of Cerebral Syphilis. By J. ALTHAUS, M.D. London: Longmans and Co. 1887.—This small volume of fifty-five pages is the substance of an address delivered before the New York Academy of Medicine, on Oct. 7th, 1886. It is chiefly interesting from the accounts given of syphilitic coma and hemiplegia; the former state, we agree with the author, has not received sufficient recognition from the general members of the profession. Dr. Althaus summarises his own experience of eight cases. They all occurred in males between twenty-five and forty-two years of age. A definite history of primary and secondary syphilis was obtained in all. In one case the coma appeared eight months after infection, in six between three and five years, and in one case seventeen years afterwards. In two cases no other cerebral symptoms had occurred before the coma,

Digitized by Google

while six of the patients had at various time suffered from giddiness, epileptiform convulsions, and transient loss of power in the limbs. The author compares "syphilitic coma" with diabetic, alcoholic, and other causes of coma, and also analyses the progress of the clinical course.

First Year of Scientific Knowledge. By PAUL BERT. Translated by JOSEPHINE CLAYTON (Madame PAUL BERT). Third Edition. Pp. 343. London: Relfe Brothers. 1886.—We read in the preface: "This little work is so popular in France that in three years 500,000 copies have been sold, and there is scarcely a school, even in the smallest village, that does not use it"—a sufficient evidence of the value of the work. It may be considered as drawn up on nearly the same lines as the Primers that were published some years ago in this country by Messrs. Macmillan, by Professors Hooker and Michael Foster, and others, except that it is abundantly illustrated, and that there is a mixture of question and answer. The subjects dealt with are, in order—Zoology, Botany, Mineralogy, Physics, Mechanics, Chemistry, and Physiology, both Animal and Vegetable. These subjects are treated in a very simple manner, and the book might well be introduced into many of our elementary schools.

1. *Guy's Hospital: Instructions for Case-taking in the Medical Wards.* 2. *Method of Case Reporting for Clinical Clerks.* By T. CHURTON, M.D.—The importance of enforcing a systematic method in the examination and record of clinical cases is fully recognised at the present day. Most manuals of practical medicine contain instructions on the lines to be pursued in such investigations, which are essential to the art of diagnosis; and the multiplication of diagnostic aids renders the need of definite rules more necessary. The "instructions," which have been in use at Guy's Hospital for some years past, are particularly useful; whilst Dr. Churton's scheme is perhaps somewhat more elaborate. In the former there is more explanation given than in the latter. The clinical clerk who will conscientiously work out his cases according to such methods as either of these points out will not only render his records of greater value, but will vastly assist himself in his own studies, and lay the foundation for accuracy and breadth of view in dealing with disease.

Elementary Animal Physiology. By GEORGE A. BUCKMASTER. Fifth Edition. Pp. 203. London: Moffatt and Paige.—This little work has been written up to the requirements of the Science and Art Department of the South Kensington Museum, the syllabus to which is placed at the head of the first chapter. Mr. Buckmaster states that the present edition has been completely rewritten, and care has been taken, in consideration of those for whom it is chiefly intended, to introduce only well-ascertained facts. He recommends the teacher to show to his class the structure and position of the organs which are the objects of his instruction. The book gives a fair exposition, in simple and easily understood language, of the main facts in anatomy and physiology, and supplies just such information as a teacher, armed with the certificate of the Science and Art Department of South Kensington, ought to know and to be able to communicate. The illustrations are sufficiently numerous and good.

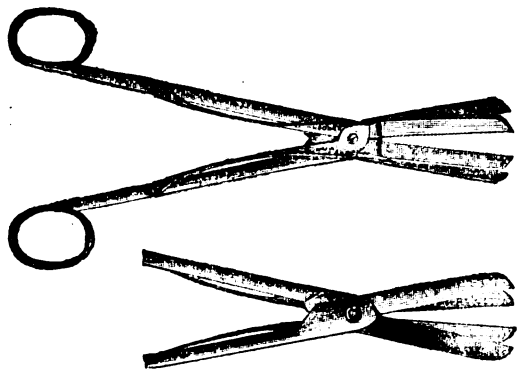
Christian Theocracy and the Dynamics of Modern Government. A Dialogue for the Times. Edinburgh: Maclachlan and Stewart. London: Simpkin and Marshall.—This is to a large extent a psychological work, and as such will interest many of our readers. It consists of a dialogue in verse, between Physicus, a "thoughtful materialist," and Psychicus, an "enlightened supernaturalist." The work as a whole may be said to consist of an effort to reconcile the views of scientific and religious thinkers respectively in their bearing upon social and political questions. Its argument, if sometimes lengthy, is for the most part skilfully presented, and is not wanting in originality of sentiment, while its diction as a rule is correct and graceful. As usually happens in such cases, neither disputant convinces the other, but there is material enough for the reflection of a third party in the utterances of each. The expression of modern sentiments in a somewhat archaic style, and a vagueness of meaning which appears at times to darken the mystery natural to this subject, are blemishes which might with advantage be removed in a new edition. Apart from these shortcomings, there is much that is fresh and ingenious in reasoning in this latest addition to speculative literature.

Wear and Tear. By S. WEIR MITCHELL, M.D.—This thoroughly revised fifth edition of an essay that originally appeared in *Lippincott's Magazine* is a most charming and thoughtful piece of work. One does not know which most to admire—the style, the matter, or the logic. Such happy combinations are of rare occurrence. This new edition comes opportunely when so much is urged on behalf of the higher culture of women. "It were better not to educate girls at all between the ages of fourteen and eighteen unless it can be done with careful reference to their bodily health." Everyone should read this *brochure*.

The Birmingham Medical Review. March, 1887.—This monthly journal is certainly one of the best of our provincial periodicals. The practitioner must find the Retrospect a very valuable feature. Dr. Suckling supplies the abstracts on Nervous Diseases; Mr. Wood White, those on the Diseases of the Eyes; Dr. Bostock Hill, those on Hygiene; and Dr. Arthur Foxwell, one of the editors, those on Therapeutics.

A Descriptive List of Anthropometric Apparatus. Published by the Cambridge Scientific Instrument Company. 1887.—This little pamphlet contains an account of the various instruments for measuring and testing the chief physical characteristics of the human body. The instruments have been designed under the direction of Mr. Francis Galton, and include dynamometers, instruments for testing height, weight, keenness of the senses, and the like.

Dod's Parliamentary Companion. London: Whittaker and Co.—In consequence of a special edition of this volume being necessitated by the early dissolution of the last Parliament and published during the autumn of last year, the issue of the new edition for 1887 has been delayed until a few days ago. The additional information which has, however, been included in the current issue fully justifies the delay. The work is now in its fifty-fifth year, the volume under notice being the sixty-first issue, and may with advantage be consulted by those desirous of obtaining succinct information respecting the hereditary and elected representatives of the nation.



UNIVERSITY OF DUBLIN MEDICAL SCHOOL.—At the prize examinations for the session 1886-87, the following were successful:—Practice of Medicine: First prize, James Magauran; second prize, William McNeely Wilson. Midwifery: First prize, Charles Fitzmaurice Harkin; second prize, Alan E. Mahood. Anatomy: Senior Division—First-class honours, Alan Mahood (prizeman), A. E. Barrington, Edward Cuffey (equal), Robert Heard, E. R. E. Ivatts, W. J. Haslitt, F. P. Nowlan, and R. L. Whitty; second-class honours, V. L. Jones, C. M. McLaughlin, W. Burkitt, and W. A. Isaac. Second Years' Division—First-class honours, R. A. Yeates, Thomas North (equal), and J. H. Head; second-class honours, T. Tate, T. Gordon, F. Myles, J. Cook, R. Dowdall, and J. Kilgariff. (The prize was awarded to R. A. Yeates, after a special examination.) Junior Division—First-class honours, D. Corrigan (prizeman), W. Dawson, T. Miles, J. Heron, E. Taylor, and V. Rutledge; second-class honours, P. Kilkelly, E. Seale, A. Adair, R. Going, H. Earl, J. Graham, E. Brook, G. Donaldson, and P. Walker.

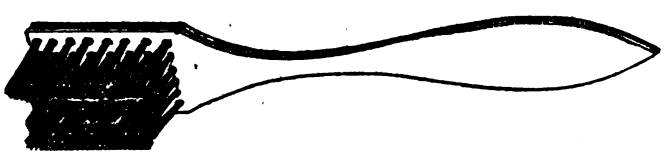
New Inventions.

A SCISSORS-CLAMP FOR EXTERNAL HÆMORRHOIDS OR OTHER SMALL TUMOURS.

IT has long been the aim of surgeons to devise an instrument that would cut and clamp by the one single movement of the finger and thumb. Such an instrument I have endeavoured to place before the medical profession. Its action is self-evident, and requires no explanation. The simplicity of the instrument at once strikes the observer; nevertheless, it has taken eight months' hard working out. The great difficulty found in practice was to get the clamp to work and clamp throughout its entire length before the



scissors-blades began to move. With the instrument as it now is this has been accomplished, the clamp being firmly closed before the blades of the scissors begin to move. Anyone requiring it can have a rack fixed on the handles, so as to fix the clamp action without holding the instrument. It has been made for me by Messrs. Maw, Son, and Thompson, Aldersgate-street, London. The instrument is elegant in form, light in weight, and very powerful.

Portland House, Cheltenham. FRED. A. A. SMITH, M.D., C.M.

A NEW FORM OF TOOTH-BRUSH.

WE have received a "three-sided tooth-brush" from Mr. Wall of Dublin, which he has invented to enable the molars and bicuspids, being the teeth most generally neglected, to be more easily cleaned. The name is rather misleading, as the hairs are arranged on one side only, as is

usual, but the free surface of the brush is deeply concave, so that the crowns and sides of the teeth are cleaned at the same time. It does its work efficiently; but, after all, more depends upon the manipulation than the form of brush used.

THE RUBBER STETHOSCOPE.

THIS is a very convenient and portable form of stethoscope, single or double, which has been produced and patented by Messrs. Arnold. It is made entirely of rubber, from ear-to chest-piece, and can be squeezed and even sat upon with impunity. It measures twenty inches in length, and is very flexible. It is therefore convenient for use where the shorter and stiffer instruments are inconvenient. It may fairly lay claim to being a handy, useful, portable stethoscope.

LIFE ASSSURANCE.

THE thirty-second annual meeting of the Whittington Life Assurance Company was held on the 28th ult., when the directors presented a report and accounts for the year 1886. By a special resolution the date up to which the accounts are made has been altered just now from May 1st to December 31st, so that practically the account now under notice is an eight months' account only. In that time the directors have received 506 insurance proposals, for the sum of £111,452. Of these 410 have been accepted, and policies have been issued for £80,213, producing an annual premium income of £2571. The number of proposals declined has been 28, for £8880; the remainder being still in abeyance. Ten annuities have also been granted for the sum of £199 14*s.* 4*d.* During the same period an agreement with the Emperor Life Office has resulted in the transfer of assurances which originally amounted to £192,866, but which under the terms of the agreement have been reduced to £142,485, for which last-named amount the Whittington has accepted liability. The net premium income of the year was £55,050, and the Assurance Fund at its close amounted to £145,532.

THE PATHOLOGY OF INEBRIETY.

THE annual meeting of the Society for the Study and Cure of Inebriety was held on the 29th ult. in the rooms of the Medical Society of London, Dr. Norman Kerr in the chair.

The President took for the subject of his address "The Pathology of Inebriety." The study was important, yet difficult; difficult because some diseases, such as certain forms of insanity, left no post-mortem traces. In the disease inebriety there was either structural degradation or functional disturbance, or both. There was a prior morbid state before the outbreak. Every sensation had a physical antecedent or coincident, normal in health, abnormal in disease. Dr. Kerr classed drinkers as (1) voluntary and (2) involuntary. Moderate drinkers belonged to the former as a rule. The latter comprised inebriates from heredity, traumatic inebriates, and inebriates from the direct or indirect effects of disease. Involuntary drinking was abnormal with a pathological antecedent. The transition from moderate to immoderate drinking was often a pathological process. The pathological antecedent might be exaltation or depression, or some other undefined morbid state. There was depression, for example, after exhausting hæmorrhage and in the crises of neurotics. Besides the pathology of the inebriate pre-paroxysmal physical antecedent, there was the pathology of the inebriate diathesis. Even in many cases of evanescent inebriety there was a diseased condition. The majority of drinkers did not respond to excitation to inebriate excess because they had no inebriate diathesis. Those who did so respond possessed this diathesis. The inebriate diathesis consisted in a deficient brain and nerve tonicity. The brain and higher nerve centres were the seat of inhibition, which power was affected by the physical state of brain and nerve; a brain imperfectly or improperly nourished heavily handicapped the power of control. This defective tonicity might be (1) inherited or (2) acquired, as also might special susceptibility to narcotics. The alcoholic was the most delicate transmitted narcotic susceptibility. The inebriate diathesis might be (*a*) latent or (*b*) developed. Alcohol was an effectual weakener of control, and specially injured brain and nerve cell, thereby being hurtful to intellect, thought, and *morale*. The pathological action on brain and nerve was often accompanied by other bodily pathological changes. Abnormal nutrition initiated these pathological alterations. By a pathological process alcohol begat inebriety. After a fatal paroxysm the post-mortem appearances were hyperæmic, involving specially the stomach, cerebrum, and meninges. Sometimes this extended to the liver, kidneys, heart, and respiratory organs. In old-standing cases these lesions were more serious, with neuroglian proliferation and tortuous atheromatous vessels. Dr. Kerr concluded by pointing out that in many cases where there were no special post-mortem appearances, there had been dynamical and psychical brain disturbances, constituting a true departure from sound health. Only by a recognition of its disease-aspect could inebriety be intelligently treated with a fair prospect of cure.

THE LANCET.

LONDON: SATURDAY, APRIL 16, 1887.

THERE is a great tendency in the mind of everyone to magnify the importance of the work in which he is engaged, and to seek better methods or further powers for its execution. It is by such efforts that improvement is made, for by constant perseverance the worker succeeds in carrying with him the greater number who know or care little about the subject matter which their more enthusiastic fellow-citizen has taken in hand. We can, therefore, fully sympathise with a desire to see perfection attained, and certainly no one who has any experience of the ill-health which can be produced by ill-constructed houses will hesitate to welcome any well-directed effort made to bring about the changes which increasing knowledge has shown to be necessary, and especially when evils are being perpetuated more on account of the want of appreciation of that knowledge at its proper value than for any other reason. When, however, it is proposed to embody in compulsory legislation for the many the principles which have been accepted by the few, it is time to consider how far the proposal is calculated to effect improvement, and whether the cost and the means to be adopted for this improvement are such as to meet with general approval.

Two Bills have during this session been brought before Parliament relating to the drainage of houses and public buildings. It is not at first obvious why other parts of house-construction, which certainly are as intimately associated with health, are not deemed worthy of similar treatment; but as matter of fact they are omitted from consideration. The reason for drainage being held to be of such pre-eminent importance is probably due to the circumstance that a large number of people are now employed in the reconstruction of house drains and their fittings while as yet no such attention has been devoted to the other conditions to which we refer. As a result, the use of the word "sanitary" is being limited, very improperly, to matters which relate to drains, and we not only hear of sanitary surveyors as a class of persons who devote their attention especially to drainage, but we have a Sanitation of Houses Bill dealing solely with this subject. The authors of this Bill are evidently dissatisfied with the manner in which house drainage is constructed in the metropolis, and feel there is little hope of improvement from the local authorities, who have since 1855 very generally neglected to exercise in the best way the powers with which from that year they have been endowed, they therefore propose to constitute an entirely new authority to take over the duties which have remained unfulfilled. The Bill unfortunately, in its inception departs from those principles which are the foundation of all modern legislation, and therefore has small prospect of becoming embodied in the Statute-book. However right may be the views held by certain professional associations, it is not probable that the Legislature will empower them, as the Bill provides, to elect the members of an authority authorised to enforce these views upon all London house-owners. The proposal to place all houses under the control of a dozen men elected in this manner is, indeed, evidently the suggestion of amateurs.

The second Bill is more modest in its ambition, inasmuch as it proposes to limit itself to dealing with buildings of a quasi-public character, such as schools, hospitals, hotels, and lodging-houses, but the area of its jurisdiction is to be wider and is to extend to all towns of 2000 inhabitants and upwards. The Local Government Board are to be an authority for the issue of licences in sanitary practice to certain persons and corporations, and for the most part are to grant these upon the certificates of a governing body to be elected in the same manner as in the other Bill. Existing local authorities are under this Sanitary Registration Bill to be permitted to have some share in this comprehensive work, for they are to open a register for all buildings which receive certificates from the licentiates, and are to prosecute the owners, lessees, and occupiers of those buildings which have not received this evidence of the perfection of their drainage. But this certificate is not to remain in force for more than five years, and the same process will therefore be repeated at the end of this period.

There is much to be said in favour of the principles of drainage which are embodied in these measures. Speaking generally, they are those recognised in the model bye-laws of the Local Government Board. When, however, it is recollected that under the Metropolis Local Management Act and the Public Health Act there is already ample machinery for bringing about, both in the metropolis and in the provinces, the ends which the promoters of these measures have in view, it may well be asked, What is the need for further legislation? The answer is doubtless to be found in the fact that the local authorities have to a considerable extent neglected to exercise these powers. This accusation is, we believe, well founded, but the remedy suggested is impossible. What is possible, however, is for the supporters of these Bills to influence the authorities, and by joining them and taking share in their proceedings they would inevitably bring about the more effectual local supervision which is required. Nor need their influence be limited to drainage alone; there are other important questions of local government not less seriously neglected, and the best results would follow if skilled members of the professional classes thus made their special knowledge a guiding power in matters which closely concern the health and prosperity of communities.

THE subject selected for treatment by the Croonian lecturer of this year is one of abiding interest; and he deserves thanks for doing much to widen and deepen that interest. The study of the pulse and its indications is, indeed, as ancient as the medical art itself; and one has only to turn to the writings of HIPPOCRATES to learn how closely and how accurately its variations were observed, with much remarkable result in prognosis and treatment. For, however faulty may have been the ideas concerning the nature of the pulse that have prevailed from the days of HIPPOCRATES almost until now, no one can venture to dispute the accuracy of observations and the sagacity in clinical interpretation that

Digitized by Google

have gathered around this subject. With the rise and progress of physiology there seemed to be a fear lest we should set at nought the old teachings and neglect too much the time-honoured practice of feeling the pulse. Nor was it without reason that the lament arose that the rising generations of practitioners were neglecting the old ways, and relying more upon instrumental aids than on the *tactus eruditus*. To feel the pulse was in danger of becoming a merely ceremonial act; and the reading of the sphygmographic tracing was held of greater import than the reading of the lessons of the finger. Not that we believe this lament to have been ever justified, or that mechanical apparatus, however cunningly devised, can equal in delicacy the educated tactile sense. There was never any real danger of converting our clinical records into a series of observations in which the observer only played the part of a skilled mechanic. Yet it is well to be reminded that the pulse is to be read with greater accuracy and certainty by the old method than by the use of the instrument which we owe to the genius of MAREY. The sphygmograph has done a great deal to interpret the significance of the pulse, and advance our knowledge of the circulation in health and disease; but as a means of clinical observation, as an aid in diagnosis, its place is necessarily subordinate to the older practice. This Dr. BROADBENT did well to state, and also to dismiss, once and for all, the pretensions to a precision which the sphygmograph cannot claim. No doubt much of the attraction that the study of the pulse had for our fathers lay in the mystery that invested it; and the care with which they separated its varieties, and allied them to differences in temperament and habit, as well as employed them in prognosis and diagnosis, was more or less influenced by the superstitious reverence in which it was held. Nor did the discovery of the circulation, the starting-point of physiology as a science, go far to dispel the glamour that invested the subject, and the true nature of the pulse remained more or less concealed. Dr. BROADBENT, therefore, did well at the outset to clear the matter of its surrounding misconceptions by laying stress on the fact that the pulse felt by the finger as it depresses the artery against a resisting surface is the sign of the momentary heightening of the blood pressure due to the impact of the ventricular systole. It cannot of course be denied that the vessel is distended at the moment of its receiving this impact; but it is not dilated. It is not in healthy conditions disturbed from its bed. Nor does it indicate the actual movement of the blood column. It is a physiological truism that the rate of the (so-called) pulse wave is wholly different from the rate of the blood current; whilst if the current be checked the pulse grows in vigour. The pulse, then, thus simply interpreted, gives information mainly upon one of the chief factors in the circulation; it indicates changes in the degree and duration of arterial blood pressure, besides informing us of the rate of the cardiac contractions, which are also often dependent upon changes in that pressure. By observation of the pulse we determine the condition of the circulation; we infer from its indications the character of the circulation in the periphery, as well as the vigour of the heart; we can learn the condition of the arterial system; and, finally, base upon physiological grounds the evidences of derangement in the circulation thus derived.

No more can be claimed for the pulse than that it is the best index we have of the condition of the circulation in the human subject, and the more the sense of touch is educated to detect the variations in the pulse, the more accurate will be our perception of this condition. The Croonian lectures have introduced us to this subject, with ample illustrations drawn from a wide clinical experience; and yet, if they have done good service in directing attention to the relations between conditions of circulation and disease, they have equally left open many paths for further exploration. Dr. BROADBENT has no hesitation in dispelling a delusion which is as old as the art of feeling the pulse. He declares that he has been unable to associate any condition of pulse, as regards low or high tension, with any special vigour of body or mind or any peculiarities of temperament. Persons with a pulse of low tension may perhaps, he tells us, be longer lived; they may not wear out so rapidly; but, if better able to endure the stress of life, they are less capable of withstanding the onset of acute disease. In the presence of such considerations and of individual differences, it would, then, seem to be hopeless to create a criterion or a standard of health from the condition of the circulation alone, in spite of all *a priori* notions to the contrary. When, then, we learn, as in the very interesting lecture that closed the series, that certain nervous derangements—notably insomnia, convulsions, and melancholia—are referable to circulatory disorder, we may fain ask whether this latter is sufficient by itself to produce these effects. As regards insomnia, the evidence adduced by Dr. BROADBENT would seem to be all-sufficient, and his very practical suggestions upon the different forms of insomnia associated with pulses of high and low tension respectively will be appreciated. As to convulsions, and their assumed induction from changes in the intra-cranial pressure due to changes in arterial pressure, it requires something more than the latter to account for the phenomenon. We admit the strength of the evidence adduced in support, especially that afforded by the arrest of the convulsions on reducing the blood pressure by bleeding; but the circulatory condition is one so common, apart from these nerve symptoms, that we must assume superadded instability of nerve tissue in all such cases, whether uræmic or otherwise. The same applies to the argument respecting melancholia, by which we gather that Dr. BROADBENT would infer that the long continuance of heightened blood tension leading to vascular changes will ultimately affect the nutrition of the brain and degrade its tissue. That calomel should purge the soul of melancholy is an interesting, if ancient, fact; but that the whole of its explanation lies in the reduction of the arterial tension, or that changes in the arterial tension are alone adequate to explain the cerebral state, are subjects which may well be further investigated. This is but one instance of the points raised in these lectures. We must refer to the text for the careful expositions, with a wealth of clinical illustration, of the variations in the pulse; the conditions of low tension and high tension, and their significance; the bigeminal pulse, and its relation to the infrequent pulse, in which only one out of every two cardiac beats succeeds in reaching the wrist; the conditions of irregularity and intermittence, of dicrotism and of abnormal frequency, especially some remarkable neurotic conditions described.

These topics were dealt with in a manner which is sure to attract attention, and cannot fail to render great service to clinical medicine by enforcing greater precision in observation and supplying fresh material for thought.

THE excellent abstracts of English and foreign chemical research which appear every month in the Journal of the Chemical Society of London render it an easy task to trace the progress which physiological chemistry is making. Nothing very remarkable has appeared for some time, but there is a constant influx of new and careful observations, valuable in themselves, and still more valuable as supplying material for new generalisations. England's share in the work is unfortunately but small. We have a few good workers, but Germany beats all other nations put together in her industry in this branch of inquiry. We cannot pretend to summarise all the discoveries of the last few months, but a short account of a few will be interesting to those who have not time to read the journals in which they have appeared.

J. SEEGEN, in *Pflüger's Archiv*, has contributed some interesting experiments on the relations of sugar in the organism. Confirming and extending his previous observations, he finds that with any diet and even during inanition the liver forms sugar, probably from peptone. The quantity of sugar is doubled during the passage of blood through the liver. In a dog weighing 10 kilogrammes the quantity of sugar formed in twenty-four hours was not less than 200 grammes. With an almost exclusively fat diet this quantity continued, and as the quantity of nitrogen excreted was only 15 grammes the sugar could not have been due to the decomposition of proteïds. In a second paper the author shows that the liver is capable of converting not only fat, but each of the proximate constituents of fat, the fatty acids and glycerine, into sugar. This is very important indeed. In the same number which records the last observation F. RÖHMANN states that ammonia, as well as its derivatives asparagine and glycocol, increase remarkably the quantity of glycogen formed in the liver. The true relation of glycogen to sugar in the liver seems still a little uncertain. Is glycogen always formed first, and is the sugar found in hepatic blood formed by the continual metamorphosis of glycogen? That seems the most probable view. SEEGEN, on the other hand, from experiments on the action of defibrinated blood and peptone on fresh liver, concludes that sugar is formed directly from fat and from albumen, but not from glycogen. In that case what becomes of the glycogen? Some interesting researches on the subject—which, however, do not appear final—were contributed to a recent number of the *Comptes Rendus* by CHAUVEAU and KAUFMANN. They confirm the statement that glycogen accumulates in the muscles during rest, but diminishes during motion. It will be remembered that, on the other hand, lactic acid increases during exercise. Glycogen, according to the last-named observer, is a storehouse of energy available at any minute for increased work.

Some interesting studies of the ptomaines, so important from the toxicological point of view, have lately been made. One of great practical value appeared in our present volume. Mr. FIRTH (THE LANCET, 1887, vol. i., p. 213), tracing the origin of an epidemic of purging and vomiting among soldiers in the Punjaub, obtained from some suspected milk which had been kept in foul pans a crystalline substance of unpleasant odour and taste which communicated similar symptoms to men and dogs. Pure milk after standing for two months yielded the same substance. In the *Chemisches Centralblatt* of last year (p. 647) appeared a paper by C. GRAM, in which some light is afforded in regard to the difficult question why some of the so-called ptomaines are poisonous while others are not. Ptomaines were obtained from putrid meat easily enough, and proved inert. But when the hydrochlorates and lactates of these bases were exposed to heat, the former remained inert, while the latter developed distinctly poisonous properties. This seems to illustrate the ready formation of poisonous ptomaines from milk. The author then proceeded to test the theory which has been started—that the active poison of ptomaine is isocholine or neurine, the isomeric variety of choline. By heating the lactate of choline, itself inert he obtained a poisonous substance similar, at any rate to a poisonous ptomaine, and possessing the peculiar odour of muscarine, which is oxy-choline. BRIEGER (*Berichte* 19, p. 3119) describes a volatile alkaloid forming crystallisable salts, and having the formula $C_5H_{11}N$, which he obtained from beef extract in which Rosenbach's microbe had been cultivated. It is monobasic.

Of interest in another direction is an hypothesis on the origin of the free hydrochloric acid of the gastric juice propounded by LANDWEHR (*Chem. Cent.*, 1886, p. 484). It is well known that common salt is decomposed by free lactic acid. This takes place even in cold solutions, as may be shown by the addition of common salt to a solution of lactic acid coloured by methyl-violet. According to LANDWEHR, who has worked on the subject in conjunction with FICK, lactic acid is formed by fermentation from the mucus of the stomach, and, acting on alkaline chlorides, liberates hydrochloric acid, which in its turn acts on the albuminoids, combining with them. As peptonisation goes on, the hydrochloric acid is liberated, while the lactate of sodium is assimilated.

Another valuable research is that of R. KULZ on the gases of parotid saliva, which was published in PETTENKOFER and VOIT's *Zeitschrift für Biologie*, pp. 23–321. Dr. HALLIBURTON's able synopsis is only a little too long to be quoted entire, and we wish we could reprint it. Saliva was drawn by a cannula from Stenson's duct, and was collected over mercury. One hundred cubic centimetres gave 7 cc. of gas, of which 1 cc. was oxygen, 2·5 cc. nitrogen, and 3·5 cc. carbonic acid. Phosphoric acid caused the evolution of from 40 cc. to 60 cc. of carbonic acid present as carbonates in the saliva. It is noteworthy that the oxygen and nitrogen are higher than in blood-serum. The uniform alkalinity is due to the carbonates, and it is found that the secretion of gastric juice, which produces great variations in the acidity of the urine, even in some cases rendering it alkaline, does not affect the saliva. This is shown by direct filtration, and also by the estimation of combined carbonic acid.

Space forbids us to speak of some other recent contributions to physiological knowledge, but a word must be spared for H. STERN's paper on the origin of the bile colouring matters (*Chem. Cent.*, 1886, p. 481). The experiments were made in two

Digitized by Google

series, in one of which the bile ducts were ligatured, and in the other the liver was thrown entirely out of the circulation. In neither case did blood, urine, or tissues show any trace of bile pigments, and the author concludes that these substances originate entirely in the liver itself.

AN influential party in the State has commenced an agitation as to the quality, or, as they put it, the purity, of the great national beverage, beer. It is alleged that beer is adulterated, not only in obvious defiance of the law by publicans, but also with the sanction or connivance of the law by many brewers. Beer, say the complainants, is a beverage made from malt, hops, yeast, and water. Anything else used in the manufacture is an adulteration, and is not only a fraud on the purchaser, who thinks he is buying malt-and-hop beer, but is also a possible and even probable injury to his health. These are serious allegations, and require most careful consideration. We will state our view of the case impartially, and shall at any rate be acquitted of sympathy with the baneful work of the adulterator.

First in the order of study comes the all-important question, What is beer? And the answer is by no means so easy as might be supposed. Beer, like wine, is of extreme and unknown antiquity. It was made by the Egyptians from barley, probably, as Herodotus asserts, because the vine did not flourish in Egypt. In some parts of Europe it took the place at a very early period of the mead made from honey which maddened the brains of more northern races. As far as malt goes, the definition of beer appears, therefore, at first glance simple enough. Taking our stand on ancient history, we may say that it is a liquid obtained by the fermentation of malt, or rather of the sweet wort obtained by the diastasic conversion of the starch of barley. But in the fermentation by which the alcoholic beverage known as beer is finally produced, the chief chemical change is the conversion of sugar into alcohol and carbonic acid; and other kinds of sugar besides the sugar of malt, now known as maltose and recognised as a distinct compound, are capable of yielding alcohol and carbonic acid by fermentation. For many years past the law has, rightly or wrongly, permitted the use of sugar in brewing, and it is very extensively employed at the present time. We have, therefore, in this as in all other cases of alleged adulteration, to inquire first, and above all, whether such a modification of the old brewing process is detrimental to health, and, secondly, whether it can be considered as a fraud upon the purchaser. We are unable to answer either of these questions in the affirmative. It has, indeed, been asserted that the products obtained in the fermentation of artificial glucose are cruder and more noxious than those derived from a natural sugar, such as the glucose of grapes or the maltose of wort. But, as far as we know, no definite proof of this assertion has been produced, and until it is forthcoming the assertion itself must be dismissed. The question of fraud is less simple, but the answer appears to us to be equally inevitable. If the Excise permit the use of any innocuous saccharine fluid in brewing, the public are thereby made aware of the fact. The demand for the beer so made will depend on its quality and its price, and on both these points the public are competent judges. The price will evidently be determined ultimately by the ordinary laws of competition. To put an extreme case, suppose that beer equal in quality to that supplied by the best-known brewers could be made for half the present cost, it cannot be doubted that those great firms would soon find themselves suffering from a competition which, although unpleasant for them, would be advantageous to the beer-loving public. If the cheap beer were inferior to that of the well-known makers, there would be, as there are now, plenty of people willing to give the higher price for the better article. But to prohibit the sale of cheap beer, unless on the ground that it was unwholesome, would be as absurd as to prohibit cheap claret or cheap tea. Of course, if the brewer or the publican sold such beer as made from malt and hops only, or, worse still, as that of well-known manufacturers, he would commit a fraud, as he would if he sold *vin ordinaire* as some celebrated vintage. But if he sells a pint of beer or a bottle of claret without further description, he commits no fraud. If the purchaser does not like it, he will go elsewhere, and the vendor will lose his customer and in time his trade.

The case of hops is still simpler. The hop-resin is a wholesome tonic bitter, but its use in brewing is, compared with the manufacture itself, quite a modern innovation. Nowadays we think it an improvement, as some may do a dash of chicory in coffee. The beer of to-day, even when made from malt and hops only, is a very different thing from the beer which washed down the breakfasts of our forefathers. Now and then in an old-fashioned inn we still meet with the "hard" or fully fermented ale which was formerly so much prized, but to most modern palates it is unpleasant. Surely no one would pretend that the brewer who left out hops altogether did not brew beer. The experience of thousands of years would contradict him. But the taste of the present time demands a bitter, and provided that the bitter be wholesome we do not see that it matters much which is used. If the brewer uses picric acid or strychnine or any other noxious substance, we have nothing but detestation for him—down with him by all means, and as soon as possible. But if he selects a perfectly harmless bitter, he has, we submit, a perfect right to do so. The beer will perhaps be nasty, but in that case the public will be no more willing to drink it than they would a decoction of senna. We have tasted beer made, we were told, without either malt or hops. It was interesting as an example of applied chemistry, but we experienced no desire to repeat the experiment.

The fact is, the cry about pure beer is but the despairing wail of the unfortunate agriculturists, for whom in their bad times everyone feels the deepest sympathy, but for whose misfortunes it is hard to find any remedy that would not be worse for the community than the disease. Simultaneously with the beer agitation, and illustrative of it, is the cry for an import duty on hops. It is not for us to discuss the vexed question of free trade *versus* protection, but it is obvious that hop-growers are not the only persons who suffer from free importation, and that if they were relieved by an import duty it is difficult to see where we could stop.

DR. BRUNTON has fulfilled the promise made in our columns that in the preface to the third edition of his well-known

Digitized by Google

work, "Pharmacology, Therapeutics, and Materia Medica," he would express his opinion regarding homœopathy in reply to the charge that he had taken many of his principal drugs from the Homœopathic Materia Medica, as well as the indications for their use. It is a favourite delusion of those who hold peculiar views that all other people's best ideas have their germ in what they think their peculiar property. The homœopaths have this delusion to a happy extent, and cultivate it diligently in their writings, though in their practice nowadays they are as little hindered as other practitioners by any exclusive principles or dogmas. Our simple object, however, just now is to give our readers the benefit of Dr. BRUNTON'S views on homœopathy as a system. First, and most pleasantly, let us record his admissions of the service it has done, though similar admissions have been made before. Dr. BRUNTON says the system which HAHNEMANN founded has done great service by teaching the curative power of unaided nature, the use of diet and regimen in treating disease, and the more than inutility—the actual hurtfulness—of powerful drugs in many instances. Dr. BRUNTON shows how homœopaths are led to be anxious about diet. "If," says he, "a patient was being treated with *carbo vegetabilis* in the thirtieth dilution, the utmost care was necessary to his diet, for if he happened to eat a single piece of burned toast at breakfast he would consume at one meal as much vegetable charcoal as would, when properly diluted, have served him for medicine during the remainder of his natural life." This is the only passage in which Dr. BRUNTON allows the ridiculous aspect of homœopathy to find full expression. We shall try to practise the same repression which he shows, and deal seriously with the claims of HAHNEMANN and his representatives.

First, Dr. BRUNTON very lucidly states what homœopathy is *not*; and, secondly, as lucidly states the very essence of the doctrine. One sentence on page xii. of the preface will give both points:—

"It is not the use of a single drug at a time, of a small dose, of a globule, nor even, as we have already seen, of a drug which may produce symptoms similar to those of the disease, that constitutes homœopathy. The essence of homœopathy as established by HAHNEMANN lies in the infinitesimal dose and the universal application of the rule *similia similibus curantur*."

The ordinary practitioner differs from the homœopathic in being free to use any drug which he knows to be of use in the case, and that in any quantity experience shows to be best. HAHNEMANN'S greatest delusion was that the causes of disease were not material but spiritual, and that medicines must be spiritualised to cope with them. Hence his infinitesimal doses. Fancy any of our best and most certainly remedial agents being used in this way and on this theory. When would ague be cured by quinine, or pemphigus by arsenic, or syphilis by mercury, if the spiritual theory of disease and drugs were adopted? Dr. BRUNTON says that HIPPOCRATES knew that in some instances a drug in small doses will cure a disease exhibiting symptoms similar to those produced by a large dose of the drug; but HIPPOCRATES had the sound sense to see, as some homœopaths have had the sense to see, that this was not a rule of invariable application; therefore not an invariable law, as HAHNEMANN taught.

Dr. BRUNTON deals with the favourite case of cinchona and ague, the action of which drug on the healthy frame, homœopaths are fond of saying, led HAHNEMANN to investigate the action of other drugs, and thus lay the foundation of his system. Dr. BRUNTON shows that, though HAHNEMANN got symptoms of intermittent fever from taking large doses of cinchona, they were probably produced by the irritant action of cinchona on the stomach, which JORG found to be produced by two-drachm doses, half the dose that HAHNEMANN took. He thinks that pork-pie might have had similar consequences, having often seen ague reproduced from heavy dinners and other stomach irritations. We are pretty familiar nowadays with the effects of large doses of quinine, the essential cure of ague, but the production of intermittent fever is certainly not one of them. Our homœopathic friends appear to have been much misled by Dr. BRUNTON'S therapeutical index, which indeed seems a sort of *omnium gatherum* largely done by an amanuensis, and so imperfect that Dr. BRUNTON had nearly left it out of his book altogether. His own description of many of their favourite remedies is very slight, and such as to show no personal belief in their specifics. His estimate of HAHNEMANN will be endorsed by all who with sound minds have gone into the study of his views. This estimate is summed up in one or two sentences: "It seems to me that in founding homœopathy HAHNEMANN has proceeded with his facts as he did with his medicines—diluting his active drugs with inert matter, and diluting his facts with much nonsense." Again: "It is the falsity of the claim which homœopathy makes to be in possession, if not of the universal panacea, at least of the only true rule of practice that makes homœopathy a system of quackery."

If homœopaths rely on Dr. BRUNTON for any countenance of their fundamental doctrines they must be wofully disappointed. He is a leader in a new and active school of therapeutics. He is bound to no master. He seeks help in understanding the use of drugs from a study of their action both in health and disease. He gives HAHNEMANN credit where credit can be given, but this does not prevent his denouncing his system, and pointing out to those who have renounced his errors the supreme duty of frankness.

Annotations.

"Ne quid nimis."

THE REGISTRAR-GENERAL'S ANNUAL SUMMARY.

THE Registrar-General's annual summary of the mortality statistics of London and other large English towns in 1886 has just been issued, and contains no statistical fact of more interest than the proof of the continued low death-rate in the metropolis. The London annual death-rate was equal to 24·4 per 1000 in the ten years 1861-70, and fell to 22·5 in the following decennium 1871-80. During the first six years of the current decennium 1881-90, the mean death-rate further fell to 20·5; the rate in the last two years, 1885 and 1886, having been so unprecedentedly low as 19·8 and 19·9. It is worthy of note that the birth-rate in London in recent years has also shown a very considerable decline. In the nine years 1872-80 the range in the birth-rate was only between 35·9 and 35·3; while since 1880 the rate has steadily fallen year by year to 32·3 in 1886. The decline in the birth-rate in recent years has not been confined to London, or even to England; but having regard to

Digitized by Google

the long-continued commercial depression, which must have affected the growth of towns, it is only reasonable to bear in mind the possibility that the population of London may not have grown since 1881 at the same rate that prevailed between 1871 and 1881. If this has been the case, the Registrar-General's estimate of the London population is too high, and consequently the calculated birth- and death-rates in nine years have been somewhat understated. Allowing for such possible understatement, however, the London death-rate in 1885 and 1886 was, beyond a doubt, unprecedentedly low. Corrected by the distribution of deaths in institutions, the death-rates last year in the five groups of registration districts were 17·7 in the west, 18·0 in the north, 19·2 in the south, 22·5 in the east, and 25·9 in the central; thus, in equal numbers living, mortality in the central group of districts was as 146 to 100 in the west districts. It may be desirable to point out that these central districts of London, where the high death-rates of former days still linger, include St. Giles's, St. Martin's-in-the-Fields, Strand, Holborn, Clerkenwell, St. Luke's and the City. On account, it may be presumed, of the difficulty of estimating the present local population, the Registrar-General does not publish rates of mortality for the individual sanitary areas, which would certainly show a wider range than do the rates in the five groups of districts. The rates of infant mortality (that is, the proportions of deaths under one year to registered births) in the sanitary areas ranged in 1886 from 121 in Plumstead, 130 in Lewisham, and 131 in Hampstead, to 199 in St. Martin's-in-the-fields, 202 in Stepney, 210 in Holborn, and 219 in the Strand. Marked, therefore, as has been the decline in the London death-rate in recent years, the excess of mortality in the central districts, whether measured by the death-rate at all ages or of infants, points conclusively to the possibility of still farther reduction.

DR. WITHERS MOORE AND THE BRIGHTON MEETING OF THE ASSOCIATION.

ALL of us remember the successful meeting of the British Medical Association at Brighton last year, and most of us will agree that not a little of the success and pleasantness of it was due to Dr. Withers Moore, whose able address supplied material for articles in the press for a week after. It is no slight testimony to Dr. Withers Moore, and to the liberality of the profession at Brighton, that, after paying the expenses of the Association meeting, a good balance was left, and was appropriated by the subscribers to the purchase of a very handsome solid silver candelabrum, which has been presented in their name by Mr. Edward Turner. The candelabrum bears the following inscription:—"Presented to W. Withers Moore, M.D., F.R.C.P., by his professional brethren, as a testimony of their regard and in recognition of his courtesy and success in discharging the duties of President of the British Medical Association during their recent visit to Brighton in the year 1886." We heartily congratulate Dr. Moore on so graceful and well-earned a tribute from his neighbours, and hope that he may long be spared to use it.

THE PRACTICAL VALUE OF THE GONOCOCCUS.

IN a paper contributed to the *Journal of Cutaneous and Genito-urinary Diseases* (March, 1887), Dr. Charles W. Allen discusses the subject of the specific micro-organism of gonorrhœa, and arrives at favourable conclusions respecting the importance and practical value of Neisser's discovery. Dr. Allen has repeatedly confirmed the observation that the gonococcus is present within the gonorrhœal pus, and even in the watery and mucous discharges of chronic gleet. The detection of the oval cocci within the pus cells is sufficient for diagnosis, the separation of the gonococcus from other bacteria being based on the fact that this microbe, after staining by Gram's method, can be at once decolourised by absolute alcohol, all other organisms remaining visibly stained. The practical value of the discovery is shown in the diagnosis of gonorrhœa in the female, and the determination of the infective character of a discharge at a long period after contagion. Evidence is given where gonorrhœa has remained long latent; and, when called into activity by excesses, has on examination proved still to retain the specific organism. The bearing of this on ophthalmia, neonatorum and on uterine disease is of great importance; and Dr. Allen goes so far as to maintain the value of the test in medico-legal practice. Of course, as he remarks, "great care would have to be exercised to include all possible sources of accidental contamination." We have not yet had recourse to the evidence of a bacteriologist in a court of law, and the belief in the pathognomonic character of the gonococcus will have to be very deeply implanted before we shall rely on such evidence. It is interesting to read the stains on linen have been determined to be gonorrhœal from the detection of the gonococcus. The proof that the gonococcus is the *materies morbi* of gonorrhœa still awaits full confirmation, inoculation experiments having mostly failed; but Dr. Allen refers to successful inoculations by Bumm of cultures, the seat of inoculation being the female urethra. In one case he used the twentieth generation of a pure culture in human blood serum, and induced a typical gonorrhœal discharge, which took five weeks to cure! As regards treatment, the discovery of the gonococcus has not apparently led to any methods superior to those already in vogue, although the use of injections of germicidal solution, as bichloride of mercury, carbolic acid, &c., has perhaps been supported. The difficulty lies in the want of thorough application of the anti-parasitic agent.

THE "DOCTOR."

THE life of the practitioner of medicine can hardly fail to be an eventful one. Apparently free from sensation, and visited not often by opportunities of high distinction, it would be superfluous to say how it abounds in occasions of fruitful effort, how little there is in it which is really little, and how freely it taxes the best energies of those who devote themselves to it. It has been truly said by some who have recently written on this subject that such observations apply most fitly to the life work of the general practitioner. The "doctor," as he is familiarly styled, without too special reference to degrees or qualifications, is a man to whom belong responsibilities the more varied that they are not solely professional, and he had therefore need to be, and commonly is, as truly human in sense and sympathy as he is well trained in the proper duties of his calling. He may be regarded as the most typical representative of his profession. There is in his case no concentration of energy on the treatment of a special illness or group of illnesses. Disease in general is the object of his attack. The whole man he takes to be his specialty, the relief of his bodily needs a large but limited field for his exertions, and he endeavours therefore, without presumption and without denying the special aptitude of pioneers in new methods of treatment, to do his duty as a healer even in so large a field. The personal qualities which befit a man so usefully ambitious had need to be as various as the ever-changing conditions of his daily life. Painstaking, with a care engendered, or at least fostered, by the discipline of student life, and maintained afterwards by a constant need of observation, endowed with a readiness which is the product of actual practice and the confidence that comes of sound instruction, he must, moreover, learn daily the great lesson of self-denial, also how to combine with a shrewd and true

Digitized by Google

understanding of human nature a sympathy no less just and real with human feeling. We have spoken of non-professional duties as now and then devolving on practitioners, and what member of the profession cannot recall occasions when he has been applied to as an adviser in matters of importance wholly foreign to his province as a medical man? At such times, as inevitable as they are undesired, a judicious mind and a careful tongue are far more to their owner than an accurate knowledge of medicine. It is the possession of these and similar elements of character, as much as technical training, which have earned for family practitioners that reputation for wisdom and integrity which we would in no boastful spirit acknowledge as an honour conferred on the profession as a whole.

INFECTION AND DISINFECTION.

IT has often been pointed out in our columns, as elsewhere, that deodorisation is one thing and disinfection another. The destruction of bad smells by no means involves the destruction of "infective agencies," but the destruction of bad smells is also an important work, and one which every disinfectant intended for general use ought to accomplish. Carbolic acid is defective in this respect, for although a good disinfectant, it does not deodorise, and simply adds its own disagreeable smell to those which existed before. Chlorine, metallic chlorides—such as the chlorides of zinc, mercury, and lead—sulphurous acid, and the alkaline permanganates are far more effectual in this respect, and each possesses in a greater or less degree the power of disinfection. Whilst the "saucer" treatment of sick-rooms with a little Condy's fluid or chloride of lime may well be distrusted, the laudation of such means as the use of euchlorine (a mixture of chlorine and chlorine peroxide) and bromine as aerial disinfectants cannot be commended. Sulphurous acid is sometimes underrated. As gas it is just as unsuitable in the presence of patients as bromine or euchlorine, but in dilute solution it is very active. Complete disinfection of an infected atmosphere in the presence of patients is impossible, but partial disinfection is easy, and the complete disinfection of wearing apparel, bedding, &c., by the prolonged use of weak solutions of metallic chlorides, sulphurous acid, and the like, can be readily effected without the slightest injury to the fabrics.

MEDICAL ATTENDANCE ON THE POOR.

A PAPER, reprinted in pamphlet form, by Dr. F. H. Alderson, on "Medical Attendance on the Poor, not Paupers," brings out many points which it is desirable to keep in view at this moment, when a committee is trying to put attendance on the poor on a satisfactory footing. Dr. Alderson clearly appreciates what we have been trying to show for years, that the provident dispensary system so far has not been a success, either as regards the people or the profession, and that many so-called provident dispensaries are worked by unqualified assistants, and are practically a fraud on the patients. The only cure, however, he sees is in the establishment of dispensaries of an improved type that will attract to their staff good, competent, and popular medical men, at rates that shall be fairly remunerative. Dr. Alderson thinks that at present such institutions cannot be entirely self-supporting, but must have a charitable element. He objects to patients being received in actual sickness, on a ready-money payment, thinking this destructive of the principle of providence or forethought. To meet the difficulty he would allow a certain number of free letters to be used by subscribers in favour of the sick, on the understanding that the latter are to join as soon as they are well. This seems to us as dangerous to the provident system as the principle of admission on special payment, which has been actually adopted by the committee now sitting. One feature of Dr. Alderson's views is the suggestion of a graduated scale of payments ranging from 6s. to 30s. for single persons per year, or 30s. to £6 a year for families. He very properly urges that the payments for children should not be less than threepence per month, as they are most prone to illness and give most trouble. If a friendly system of co-operation between the hospitals and dispensaries could be arranged, it would be good for both. The hospitals would have the dispensaries as a clinical field for the study of common diseases, and the dispensaries would have the right of recommending fit cases to the hospitals, or asking for a consultation with the hospital staff, if necessary. We do not know whether Dr. Alderson is quite right in saying that the classes whose benefit is sought by the committee over which Sir Spencer Wells presides so ably are only the poor, not the industrial classes.

PERINEAL RUPTURES IN THE BRUSSELS MATERNITY.

IN Professor Kufferath's maternity department in Brussels the smallest lacerations of the perineum are sutured immediately. During the year 1886 sixty cases of laceration occurred, varying in extent from one centimetre to four centimetres, the sphincter not being involved in any case. These were mostly operated on by students, with the result that complete primary union was obtained in fifty-one cases, and incomplete union in five more, while in four cases the operation was entirely unsuccessful. The method adopted is as follows. The patient is placed in the (dorsal) obstetrical position, the thighs being separated by assistants. The vagina is washed out by a copious antiseptic injection, and the vulva and perineum scrupulously cleansed, any dead parts being cut away from the torn surfaces. A plug of charpie impregnated with corrosive sublimate is introduced into the vagina, so as to prevent the flow of blood inconveniencing the operator. The left lip of the wound is seized between the thumb and index finger of the left hand, and the needle, which has, together with the silver wire attached to it, been previously disinfected, passed into the skin half a centimetre from the torn edge. When it has reached the bottom of the wound, its direction is changed and it is passed through the opposite lip, its point emerging at a spot corresponding exactly with that at which it was first introduced. Any hæmorrhage produced by the introduction of the needle is removed by charpie impregnated with corrosive sublimate, and the wire is not tied until this has been done. The first suture is placed at the most posterior part of the wound, and the rest near together, one after another, till the fourchette is reached. If necessary, some superficial sutures are added. In this way the edges are retained in close juxtaposition, a condition indispensable for preventing the accumulation of blood and the lochia in the deep parts of the wound, otherwise union cannot take place. The wound is dressed with iodoform, the legs being left quite free. Antiseptic vaginal injections are given twice daily, followed by renewals of the iodoform dressing. On the sixth or seventh day the sutures are removed, the patient being placed for the purpose in the lateral position. Dr. Tournay, who communicates these particulars to *La Clinique*, believes that when the operation as described is properly performed, it is, or ought to be, invariably completely successful, as indeed it always has been in his own hands, whether in the clinic where he is assistant or in private practice. It will be observed that he does not introduce the finger into the rectum, or pass the needle so as to make the entire circuit of the wound, and that he omits all reference to the use of the catheter after the operations, matters which are considered by many writers indispensable to the perfect healing of perineal ruptures.

THE FRENCH ENTRANCE EXAMINATIONS FOR MEDICAL STUDENTS.

M. LORTET, dean of the Medical Faculty of Lyons, has just presented a report to the Council of the Faculty on the subject of the entrance examination required in France from all medical students intending to proceed to the Doctorate This consists of the Baccalauréat ès Lettres and the Baccalauréat ès Sciences modified with regard to the mathematics. M. Lortet appears to have no fault to find with the first of these examinations; but as to the second, or modified B.Sc., he says that men come up as a rule very badly prepared, some of them getting plucked five or six times, and those who do pass doing so with a minimum of marks. Again, the science which the candidates have learned is of but little real use to them, as they have to attend the chemical and other scientific courses afterwards, the medical faculty not considering the courses in the Lycées nearly good enough. It would, in the opinion of M. Lortet, and apparently in that of most of the medical faculties of France, be quite sufficient to insist upon the possession of the Baccalauréat ès Lettres only for medical students leaving them to learn their science once for all at their medical school. A year would in this way be gained. The Lyons examiners would appear to be particularly and increasingly severe, and to have frightened away most of the candidates to other faculties where more merciful boards are to be found, the result being that the Lyons School is suffering from a certain amount of competition downwards. The number of candidates for the modified baccalauréat in Lyons in 1877 was 94, of whom 29 passed; this number has been rapidly decreasing, being 15 in 1885, of whom 4 passed, and 12 in 1886, of whom none passed. Several other medical schools of certainly not superior note to that of Lyons admitted in 1885 a much larger number—e.g., Bordeaux admitted 50; Dijon, 29; and Toulouse, 67. M. Lortet concludes his report by urging the Faculty to transmit to the Minister of Public Instruction a request that the modified Baccalauréat ès Sciences may be dispensed with altogether.

THE EFFECT OF HYDROCHINONE ON URINE AND UREA.

DR. ANTAÏFF, working in Professor Sushchinski's pharmacological laboratory, has recently investigated the effect of the presence of hydrochinone on the alkaline fermentation of urine and on urea itself. Hydrochinone is represented by the formula $C_6H_4(HO)_2$—being, in fact, benzole in which two atoms of H are replaced by hydroxyl; it is isomeric with paracatechine and with resorcine. Mering found it in the urine after arbutine had been given, and Baumann and Presse in that of persons who were taking carbolic acid. Dr. Antaëff found that when 2 per cent. of hydrochinone was added to fresh urine the latter remained entirely free from alkaline fermentation. After twenty-five days no cloudiness or precipitate had formed, there was no ammoniacal odour, the smell being just like that of fresh urine; the reaction, too, was acid. When only 1 per cent. of hydrochinone was added some deposit formed after a time, but there was no ammoniacal odour, and the reaction only became neutral. Observations were then made on solutions of urea. To 100 cubic centimetres of distilled water were added one gramme of urea and one gramme of hydrochinone. After twenty-four hours 17 per cent. of the urea had been decomposed. When the hydrochinone was omitted, only 1 per cent. of urea was decomposed in the same time. Again, when larger quantities of urea were present, hydrochinone in the same quantity as before exerted a still greater effect in increasing the decomposition; thus a 3 per cent. solution of urea lost 0·2 per cent. of its urea, but when hydrochinone was present it lost 13·5 per cent. The solutions of urea with hydrochinone turned a light cinnamon colour, which became darker on standing. The destruction of urea by hydrochinone was believed by Dr. Antaëff to be due, not to a fermentation process, but to a chemical action of hydrochinone upon urea. Dr. Dianin suggests that the action may be analogous with that of acids on urea, which cause it to break up into ammonia and carbonic acid, with this difference, however, that hydrochinone probably forms a compound with the ammonia as it is disengaged, which is not easily decomposed by hypobromite of sodium. This theory will also account for a certain deficiency in nitrogen which was always observed in azometric determinations of urea in solution with hydrochinone.

POOR-LAW AND SANITARY HOSPITALS.

WE have elsewhere adverted to the need for hospital accommodation for infectious diseases in the Toxteth-park urban district—a district which adjoins Liverpool, and as such is very liable to receive infection. The Toxteth guardians have been considering the same subject, and at a recent meeting a proposal was made to arrange with the sanitary authority for the use by them of the new infectious hospital attached to the workhouse in Smithdown-lane. This discussion raises the whole question as to the propriety of sanitary authorities using Poor-law institutions for the isolation of the infectious sick. As to this, we would at once say that unless the Poor-law infectious hospital can be entirely transferred to the sanitary authority, and be administered by a staff wholly different from that belonging to the workhouse, the idea should not be entertained. So long as the hospital remains vested in the hands of the Poor-law authority it is a pauper institution, and all persons entering it are thereby pauperised—a result which sanitary authorities desiring to protect health in their districts have no right to bring about. Formerly, these workhouse fever hospitals were the only ones available, and they were used without any strict inquiry into the social status of the sick: but of recent years new ones have, we believe, not been erected unless there was every prospect of their being needed for essentially Poor-law purposes. The position which Toxteth occupies with regard to Liverpool doubtless affords a sufficient reason for the erection of this new pauper hospital, and the mere fact that it has not been used during the twelve months for which it has been opened is no proof whatever that it is not needed for the precise purposes for which it was erected. The question has now been referred to the General Purposes Committee, and it is important that they should understand at the onset that so long as the hospital belongs to the guardians it cannot be legally used for any non-pauper purposes. Whether a hospital just erected for Poor-law purposes ought now to be alienated from those purposes and transferred to the sanitary authority is another matter, into which we need hardly enter at present.

THE CONTAGIOUS DISEASES ACTS IN INDIA.

A PARLIAMENTARY paper published recently gives a summary account of the machinery by means of which the Contagious Diseases Acts are administered in India. In itself the information is sufficiently interesting to justify its publication, although it might have been considerably improved in this respect by the addition of such statistical facts as would have given the British public some idea of the number of persons affected by them and the character of the work being done. That, however, was probably not the object with which this return was called for. The intention of the promoters no doubt was to attack the administration of these Acts in India, as they have attacked them at home. Experience shows that in this crusade the sanitary results obtained go for little or nothing, and that the responsibility of the Government for preventable mischief

Digitized by Google

is a doctrine to which the repealers will not listen. Better in their view the nameless horrors of surreptitious vice—so long as it is branded with the name of vice—than the restriction of the ravages of a disease from which countless innocent victims as well as the vicious have to suffer. As yet, however, we hope that wiser counsels will prevail. It is bad enough that our military stations at home have lost the benefit of this useful, though unpopular, legislation. It would be a still worse case if the benefit of such precautions were lost to our army in India. The ostrich policy of turning prudishly away from the consideration of such problems and burying our heads in the sand of *laisser faire* can lead to nothing but disaster.

FATAL RESULT OF INTRA-UTERINE MEDICATION.

DR. OTTO ENGSTRÖM of Helsingfors relates the following case in a Swedish medical journal. A woman, aged thirty-seven, had suffered from persistent metrorrhagia. The uterus was retroflexed, but no signs of past or present inflammation could be discovered. It was replaced and scraped out with a Simon's sharp spoon, two small spoonfuls of hyperplastic tissue being removed. A solution of iodine in iodide of potassium at 45° C. was then injected; the relative proportions of iodine, iodide of potassium, and water being 1, 2, 30. No fever and scarcely any pain followed. In five days' time a second injection was used, the temperature being 40° C., and the relative proportions of iodine, iodide of potassium, and water 1, 2, 10. No pain was experienced, and the patient walked up- and down-stairs. On the evening of the second day, however, a rigor came on, followed by pyrexia, abdominal tenderness, diarrhœa, and convulsions, death occurring two days later. At the necropsy there were found broncho-pneumonia, chronic œdema of the lungs, endocarditis, and purulent peritonitis. The substance of the uterus was soft, friable, and grey-coloured, containing specks of blood and lymph. The peritoneum over the uterus was of a yellowish-red colour and covered with puriform matter. The Fallopian tubes and their fimbriated extremities were not dilated or particularly reddened, and the mucous membrane presented no abnormality. The os uteri was too small to admit a fine probe. A large quantity of pus occupied the peritoneal cavity. Dr. Engström does not think any of the injection can have passed into the tubes, still less into the peritoneal cavity, and believes that the fatal peritonitis was due to an extension of the inflammation directly from the uterine wall to the peritoneum.

HANGING AS A SOURCE OF PLEASURE.

IF those are to be believed who, having been more or less hanged, have been resuscitated, and have narrated their experiences, the much-commiserated victim of the law's extreme penalty is not wholly miserable. It would seem that even death "sus. per coll." has its ameliorating conditions or circumstances. One sufferer in the religious cause in France is said to have "complained" because he was called back to consciousness from an experience of surpassing delights, in which he enjoyed the pleasure of gazing upon the most beautiful scenery. The immediate sensation of pain is momentary; and it would appear not unlikely that, in our anxiety for the avoidance of needless annoyance to those we put to death judicially, we may be actually increasing their sufferings and diminishing their pleasure. The instantaneous deaths have all the pain and little or none of the pleasure. Slowly induced congestion of the brain may be the least painful, and if only the blood pressure be effectually raised at the centre that sees, the beautiful light and charming scenery are enjoyed in the highest perfection. The subject is a grim one, and we are not sure that the new view of hanging experience tends to make the death penalty increasingly deterrent, but it is right that both sides of a question which the late Mr. Whalley once excited the merriment of the House of Commons by describing as "a poor man's question" should be carefully considered at all costs.

THE AIR IN SHIPS' HOLDS.

DR. A. T. DOBROTVORSKI has recently published the results of a number of observations on the character of the air in the holds of Russian men-of-war from a hygienic point of view. In reviewing the works of previous writers on this subject, he claims for a Russian observer, "N. T.," who wrote an article in the *Morskoï Sbornik* (Nautical Magazine) for 1869, the credit of being the first to make definite analyses of the air in ships; observing that Parkes, in the second edition of his book, published in England in 1866 and translated into Russian in 1869, states that the composition of the air in holds is not known. "N. T." found 1·19 per 1000 of carbonic acid on the upper deck of the monitor *Bronenosets* during the night when forty-one men were sleeping there. Dr. Dobrotvorski's estimations of CO_2 were made by means of a modification of Pettenkofer's method proposed by Nagorski, which, however, he does not further describe, though he says it is the most exact and convenient plan, only requiring small bottles of the air. For the free and albuminoid ammonia he employed Dr. Fox's method, as given in his "Sanitary Examinations of Water, Air, and Food." This, as being probably but little known in Russia, he describes pretty fully. In the bilges of the *Peter the Great*, the largest vessel in the Russian navy, the moisture was found to be 89·5 per cent., the CO_2 4·6 per 1000, the free ammonia 0·026 milligramme per 1000 litres, and the albuminoid ammonia 0·246 milligramme. The highest estimates of CO_2 were in frigates and floating batteries, the lowest in clipper ships. In the engine-room of the *Admiral Spiridoff*, an iron frigate built in 1868, the CO_2 was found to be as high as 8·22 parts per 1000. The ammonia found varied a great deal—being, however, only slightly higher in the frigates and batteries than in clipper-built vessels, and bearing little relation to the quantity of CO_2; thus, in the bilges of the *Peter the Great* the albuminoid ammonia was 0·246 milligramme per 1000 litres, in the engine-room of the *Admiral Spiridoff* 0·154 milligramme, while in a part of the floating battery *Pervenets*, where the CO_2 was only 2·37 per 1000, the albuminoid ammonia was 0·564 milligramme per 1000 litres.

INSANITARY BETHNAL GREEN.

THE Mansion House Council, which has investigated the sanitary state of many parts of the metropolis, with reference especially to the housing of the poor, has brought under the notice of the Local Government Board the state of a number of houses in Bethnal-green, where, it is implied, there has been considerable neglect. According to a letter addressed by that Board to the Bethnal-green vestry, it is said that the plan followed on a former occasion—namely, that of requesting the Home Secretary to appoint an officer to investigate the circumstances of the alleged complaint—will be followed this time.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Wilhelm Brummerstadt of Rostock, well known for his writings on obstetrical and gynæcological subjects. Dr. Johann Streng, Professor of Midwifery in the Bohemian University of Prague. Dr. Andreas Boecker of Berlin, a well-known laryngologist.

TESTIMONIAL TO DR. KENNEDY OF MERCER'S HOSPITAL.

AT a meeting recently held at the Shelbourne Hotel, Dublin, Sir Charles Cameron in the chair, it was resolved to present Dr. B. Burke Kennedy, resident surgeon of Mercer's Hospital, with an address expressive of sympathy with him in the trying ordeal through which he has passed; also to open a "Defence Fund" to pay the heavy legal expenses to which he was put. It will be remembered that a charge of manslaughter was made against Dr. Kennedy for removing a delirious patient from an ordinary to a special ward. After the evidence for the prosecution had been heard, the jury stopped the case, and returned a verdict of acquittal, with the following rider:—"We consider that, according to the evidence, Dr. Kennedy should not have been subjected to the hardship of a prosecution." Subscriptions to the fund should be forwarded to the hon. treasurer, Dr. McVeagh, 1, Rutland-square East, Dublin. A copy of the Report of the Corporation Commission of Inquiry, and of the Abstract of Trial and Verdict in the Law Courts, may, we understand, be had on application to the hon. secretaries—George H. Kidd, M.D., L.R.C.S.I.; Arthur H. Benson, M.D., F.R.C.S.I.; Robert Wade, F.R.C.S.I.; and F. Alcock Nixon, F.R.C.S.I.

THE OVER-STOCKING OF THE PROFESSION.

WE have long pointed out that the creation of new doctors in Great Britain exceeds the waste of the profession by some hundreds yearly. In Germany the increase is so steady and serious, that at the recent meeting of the German Physicians' Association (a society organised, as the *New York Medical Record* puts it, in the social and economic interest of the profession, rather than in that of medical science) an address was issued advising young men against entering the profession as the prospects are becoming worse yearly. The *Record* takes some warning from this action of the German Association. It understands it to mean that there will be a larger importation of pure German physicians into the States. And our contemporary adds, with much force, "as our colleges turn out from 4000 to 6000 new doctors every year, the prospect is, of course, most pleasant."

CHRONIC URETHRAL DISCHARGE.

THIS ailment is one which not unfrequently proves singularly intractable, and calls into requisition all the acumen and practical skill of the surgeon for its successful treatment. It is a disorder of a symptomatic nature which owns many sources of origin, mostly local, but sometimes in part constitutional. What is the appropriate remedy in one case may be, on the whole, unsuited to another, so that empiricism in medication is apt to fail where a rational course of procedure gives the happiest results. It must not be assumed that all cases of urethral catarrh are gonorrhœal—we use the latter term in its clinical, not its pathogenic sense,—for not seldom one meets with patients suffering from chronic discharge, concerning whom the practitioner elicits no evidence to prove or suggest that the disorder is the consequence of impure intercourse. The menstrual flux, lochial flow, or the acrid vaginal secretion often met with in pregnant females, are severally capable of setting up acute or subacute urethritis, which when once initiated may give considerable trouble to eradicate. The complaint, whatever its cause, is, in the ordinary routine of practice, too often assumed to be entirely local in its nature as it was in its incidence. But just as in a strumous individual some slight irritation is apt to start a troublesome attack of eczema, so in patients of a pyogenic tendency urethral catarrh may vary in intensity and duration far beyond the measure of its primary cause. In such cases ferruginous tonics, a bland regimen, and mild astringents are the appropriate treatment. Again, we have known instances in which the removal of obstruction to the free circulation through the hæmorrhoidal vessels has acted beneficially on the urethra—such, for example, as the removal of piles or the cure of chronic constipation. If the discharge is dependent on urethral granulations, the site of which is frequently indicated by increased sensitiveness to catheterism and resistance to the passage of the instrument then gentle pressure with a bougie, continued for, say, a quarter of an hour at a time and repeated two or three times a week, may suffice. Or the pressure may be combined with the application of some astringent in the form of soluble gelatine medicated bougies. On the supposition that the morbid action depends on the vitality of certain microscopical organisms, some surgeons advise the employment of antiseptics, such as iodoform, eucalyptus oil, &c., weak solutions of perchloride of mercury, and the like. These chemical substances are inimical to the life of micrococci, and, moreover, tend to check the physico-chemical reactions involved in the decomposition of animal matter. We cannot deprecate too strongly the unrestricted use of strong astringents—or even of weak solutions for the matter of that; for we are convinced that it is not a rare event for chronic urethral discharge to be perpetuated by the very means adopted for its removal. Nay, further, it is not too much to assert that not a few cases of stricture owe their origin to the practice of doing too much. It should be borne in mind that urethritis has a tendency to get well of itself, and that the tendency may fail in giving place to accomplishment on account of meddlesome surgery.

THE DUCHESS OF CUMBERLAND.

FROM information just received from our correspondent at Vienna, we learn that the preliminary stage of the illness from which the Duchess of Cumberland has been suffering was one of long duration, characterised by languor, insomnia, and disinclination for food, together with anxiety and the possession of painful delusions. Her constitution, which has always been somewhat delicate, appears to have been severely taxed by the troubles incident to maternity. The physical and mental condition of the Duchess is now, however, greatly improved. Artificial feeding has never, in spite of rumours to that effect, been found necessary, and sleep is now obtained without resort to hypnotics. The cheerfulness significant of returning health is also beginning to be manifest. The physicians in attendance express their opinion that the case is a curable one, and that gradual progress towards recovery may be anticipated.

A DANGEROUS TOY.

AN inquest was held on the 6th of April on the body of a boy aged eight years who had died suddenly from asphyxia. At the post-mortem examination, a toy, only too well known as "a squeaker," with the indiarubber bag attached, was found impacted in the larynx. This had formed a most perfect plug, completely closing the air passage. It is to be hoped that this accident may be noted by parents, and the use of this toy forbidden; not only will they thus be relieved from a source of anxiety, but their friends from one of much annoyance.

THE MARGARET-STREET INFIRMARY.

DR. John Beckett, Dr. Tuckey, Dr. Roberson Day, and Mr. Kenneth W. Millican have been elected to fill vacancies at the above infirmary. We are not aware whether all these gentlemen are avowed homœopathists; if they are not, we can but deplore their acceptance of the posts.

REPORTED ILLNESS OF MEMBERS OF PARLIAMENT.

THE Right Hon. the Speaker of the House of Commons has authorised us to state that a paragraph which appeared in several of the morning papers on Wednesday (13th inst.), to the effect that within the last fortnight six members of the Lower House had been incapacitated from attending the debates by diphtheria, is without foundation.

THE ASSISTANT-PHYSICIANSHIPS AT GUY'S.

WE understand that the governing body at Guy's have determined that they will receive and entertain applications from physicians outside the hospital for at least two of the vacancies at present among the assistant-physicians. The appointments will be filled up at the Court of Governors to be held on April 27th, and candidates are requested to send their applications to the treasurer prior to this date. We cannot but think the Court well advised in thus opening up its appointments and in seeking to obtain the best available men for the vacant posts. The example is worthy of imitation by lesser schools.

THE LEICESTER SICK BENEFIT SOCIETY.

MR. JAMES WILLAN, of 62, Humberstone-gate, Leicester, after appearing repeatedly before the borough magistrates for neglecting to show a member the books of the Leicester Sick Benefit Society, has been fined £5 or one month's imprisonment. The magistrates were dissatisfied at the defendant for not producing the ledger, and the vague excuses made by him for not doing so. The financial affairs of this society, and the representation of them by the secretary, have been the subject of much adverse criticism during the last few months, and apparently with too much reason. The defendant gave notice of, but does not seem to have yet made, appeal.

CHILDREN'S TEETH.

IT is gratifying to learn that the importance of proper attention to the teeth of school children—a subject on which we have more than once commented—is coming to be more fully recognised by managers of schools. Thus, at the North Surrey District School, Mr. Henry J. Moxon, L.D.S., has, at the solicitation of the managers, and with the approval of the Local Government Board, just delivered a popular lecture to the officers and senior scholars of the institution, on the construction, function, and means of preserving the teeth. This, we believe, is the first occasion on which an address of the kind has been given in a Government school, and it offers an example which may well be followed in other similar establishments.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Privy Councillor Olshausen of Halle has accepted the invitation to fill the late Professor Schroeder's chair of Midwifery, and will commence his lectures on May 1st.

Buda-Pesth.—A new department for ear diseases in the Rochus Hospital has been established under the charge of Professor Böke, who gives clinical instruction there.

Marseilles.—The Medical School has recently increased considerably, and a chair of Bacteriology has been founded, for which the Council-General of the Bouches-du-Rhône has voted the sum of 2000 fr. The Chamber of Commerce has passed a resolution expressing its desire that the Medical School, which is at present one of the *écoles de plein exercise* or second-grade schools, should be converted as soon as possible into a faculty or first-grade school. It is stated that the number of entries has been for the doctorate 129, and for the licence (as *officier de santé*) 114, besides 381 in the Pharmaceutical School.

Rostock.—The chair of Botany, vacated by Professor Göbel, who has gone to Marburg, has been offered to and accepted by Dr. Paul Falkenberg, Extraordinary Professor in Gottingen.

Würzburg.—The vacant chair of Psychological Medicine, which was offered to Professor Jolly of Strassburg, having been declined by him, will now be offered to Dr. Rieger, *privat docent*.

TEACHING AT THE "ZOO."

IT may not be generally known that by the combined liberality of the Zoological Society and the Association for the Extension of University Teaching, facilities are now offered to students desirous of obtaining a real and practical knowledge of the science of zoology. Familiar demonstrations will be given by Professor Beddard to all who choose to attend during the next three months, at a cost not exceeding the bare price of admission to the gardens. In arranging this course the University Teaching Association has taken a decided step in the right direction, and it is to be hoped that further advances will be speedily made towards the development in the teaching of physical science.

ON the 12th inst. Dr. Daniel Rutherford Haldane died at his residence in Edinburgh. The deceased took the degree of M.D. at the University of Edinburgh in 1848, and became a Fellow of the Royal College of Physicians in 1852. He was a Fellow of the Royal Society of Edinburgh, and several years ago received the degree of LL.D. from the University of Edinburgh. Dr. Haldane was for some time president of the Royal College of Physicians of Edinburgh, and represented the College in the General Council of Medical Education and Registration of the United Kingdom.

THE sudden death on the 8th inst. is reported of Mr. J. J. Eberle, of Thirsk. The deceased was well known in the profession, having for many years acted as a private tutor for the various medical examinations of the licensing bodies.

AT the next meeting of the Royal Statistical Society on Tuesday evening next, the 19th inst., at the Royal School of Mines, 28, Jermyn-street, a paper on "Class Mortality Statistics" will be read by Mr. Noel A. Humphreys.

THE circumstances attending the sinking of the emigrant ship *Kapunda* have largely influenced the Board of Trade in the determination to ask for the appointment of a Select Committee to inquire into the subject of loss of life at sea.

ANTITHERMIN is the latest introduced antipyretic agent. It is allied in its chemistry to antipyrin; phenyl-hydrazin-levulinic acid is the chemical name.

DR. ROBERT BARNES has been elected an Honorary Fellow of the Chicago Gynæcological Society.

PRESTON MEDICO-ETHICAL SOCIETY.—At the annual meeting of this Society, held on Thursday, March 31st, the following members were re-elected officers:—President: Dr. Moore. Vice-President: Dr. Lonie. Treasurer: Dr. Walmesley. Committee: Dr. Smith, Dr. Garner, Dr. Green, Dr. Rayner, Dr. Trimble, and Dr. C. Rigby. Hon. Secs.: John Holden and J. J. Byrne. The subjoined resolution was also passed: "That, in the opinion of this Society, it is very desirable that an independent inquiry be made on the sanitary condition of the town by the Local Government Board, more especially in regard to the high mortality."

VOLUNTEER MEDICAL STAFF CORPS: EASTER MARCH.

THREE companies of this corps joined in the Easter manœuvres of the Volunteers, two going to Dover and one to Eastbourne. The Dover contingent, about 100 strong, with full complement of officers, left Charing-cross on Friday morning, under the command of Surgeon-Major A. T. Norton. The men were divided into two companies under Surgeon-Major Casson and Surgeon Willett. The Adjutant, Surgeon Lees Hall, M.S., and Surgeons Lake and Raw also accompanied their seniors. On Friday night the corps took part in the night attack, and during and after the fight kept up careful search for wounded men over the scene of the fight. At Dover the headquarters of the corps were marked by a conspicuous white flag emblazoned with a red cross. On Saturday the force had a very long tiring march, moving in three columns by different routes from Bridge and Canterbury to Dover. Each column was accompanied by an ambulance and water-cart, and the senior medical officer was responsible for the medical arrangements, Surgeon Whitmore (3rd London), Surgeon Jones (14th Middlesex) and Surgeon Buck (17th Middlesex), being in charge of the columns. The Volunteer Medical Staff Corps accompanied the centre column. Only eight men fell out during the day, which is a matter of congratulation, considering that the right column marched twenty-three miles over very rough country. In this column only two men fell out.

On Monday the bearer companies marched past with great *éclat*, their smart appearance and well-locked up ranks eliciting much approbation. A company of the V.M.S.C. also went to Eastbourne under Surgeon Squire. On the Tuesday before Easter, however, a small party of fourteen men under Serjeant MacLeod very pluckily set out to march to Eastbourne with regulars. The main body of the company marched on Friday morning, Surgeon Valentine Matthews joining it later on. The company was well equipped with mule litters, and had its own signallers. At Eastbourne a station hospital was established. Ample opportunity was afforded the men of learning what real work meant, and their smart appearance elicited hearty applause on more than one occasion from on-lookers. Staff Quartermaster Robertson and Quartermaster Clarke accompanied the Dover companies; Quartermaster J. J. Thomson accompanied the Eastbourne company, and from the careful preparations of these gentlemen, combined with the invariable hospitality of the medical men throughout the districts through which they marched and were stationed, most certainly the V.M.S.C. had no cause of complaint.

Some real surgical work occurred during the day, showing the efficiency of the medical staff and the men attached to their corps. It appears that towards the end of the action three gunners of the 3rd Kent Artillery force were injured by the premature discharge of a gun. There happened to be no surgeon with the battery, so that their comrades proceeded to render "first aid" whilst a surgeon was sent for. Mounted officers galloped off in two directions—one to the field hospital and the other in the direction of the bearer company. Acting Surgeon Pearce, M.D. Lond., of the "Artists," on duty at the field hospital at Maydensoule Farm, speedily providing himself with a surgical haversack, rode across country at once to the scene of the accident. He found that Gunner Whitmore, who was seriously injured, had been placed on a stretcher made of a hurdle, an improvised tourniquet had been efficiently applied above the elbow, and the shattered hand well bandaged. He was being borne towards a neighbouring farm near the scene of the accident. He was then carried into the farmhouse and laid upon a couple of tables. At this moment Surgeon Raw and Quartermaster Webb, A.M.D., with a detachment of the Volunteer Medical Staff Corps, all of them medical students from St. Bartholomew's, London, Guy's, and St. Mary's Hospitals, arrived in an ambulance waggon completely equipped with surgical appliances and medical comforts. Surgeon Pearce took charge of the case, and before proceeding to further steps Surgeon Raw administered chloroform, and the shattered limb was examined after reapplication of a tourniquet, the fracture set, wounds dressed, and the injury of the eye and scorching of the head attended to. The unfortunate man was placed in an ambulance waggon and conveyed to Dover Castle Station Hospital, where the limb was amputated below the elbow by Surgeon-Major Greenhill, G.M.O., Surgeon-Major Slaughter, Surgeon Begg, M.S., with the active assistance of Surgeon Raw and Acting-Surgeon Pearce. The other injured men, who were much scorched about the face, were conveyed to the field hospital, and received attention from Surgeon Bourlton, M.S. The whole medical administration for the day reflects great credit upon the medical authorities, and the accidents which we regret to have to record found the medical aid of the Volunteer department, of which we have heard so much lately, not wanting when the time of real emergency arrived.

THE LANGMORE DEFENCE FUND.

WE published last week from Dr. Leachman a letter headed "A Victim of the Law," and appended some comments thereto, in which we intimated that a subscription had been started by the Council of the Metropolitan Branch of the British Medical Association to reimburse the gentleman referred to in that communication, the costs of the defence in a suit (Hughes *v.* Langmore and others) which, it will be remembered, came on for hearing before Mr. Justice Manisty in November, 1886, and which resulted, after four days' trial, in a verdict for the defendants with costs. The amount of the costs was considerably increased by the fact that, on the plaintiff's petition, one of her witnesses (the doctor who was actually attending her at the time of Dr. T. W. Langmore's visit) was examined by special commission; but at the trial the plaintiff refused to put in the evidence thus taken, or to place the witness himself in the box, though it was elicited that he had been quite recently, and it was inferred that he was then, resident in England. The plaintiff being a person of small means, Dr. Langmore has not been able to obtain payment from her of any portion of the costs awarded him, and has been called upon to pay legal expenses amounting to £240 8*s.* 1*d.*, irrespective of personal expenses connected with the action, and the inevitable loss of time and practice. Donations should be sent to Mr. George Eastes, M.B., 69, Connaught-street, Hyde-park-square, London, W., one of the honorary secretaries of the Metropolitan Counties Branch.

The following subscriptions to the fund have been already promised or received:—

Mr. W. Adams	...	£3	3	0	Sir W. W. Gull, Bart.	...	£2	0	0
Mr. C. A. Aikin	...	2	2	0	Dr. C. J. Hare	...	5	5	0

PASS AND PLUCK IN BRUSSELS.—At the recent examinations in the University of Brussels for the Doctorate in Medicine, one out of ten was rejected for the first Doctorate, and four out of ten for the second, while all the seven candidates for the third Doctorate, or final examination, passed, so that only five of the whole twenty-seven candidates failed to satisfy the examiners. From the list of names published it would appear that there were no candidates, or at least no successful ones, from this country. In the two preliminary examinations for the title of candidate dealing with anatomy, physiology, chemistry, &c., six candidates were rejected out of a total of sixteen.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bedford Urban District.—Dr. Prior deals at considerable length in his annual report for 1886 with the question of isolating cases of infectious diseases. Bedford is one of those towns which can make a sort of plea that such accommodation is not pressingly needed by them, because there is a special fever hospital at the General Infirmary, and also a so-called small-pox hospital just outside the town. But the fever hospital belongs to a body of governors; it is unfit for the reception of two kinds of infectious fever, although the different floors were at one time so used before disaster occurred in consequence, and as a matter of fact it does not answer the public health requirements of the district. Then the small-pox hospital is an iron shed belonging to the guardians, and as such leading to the pauperisation of those who use it; it is also a deterrent and unsuitable building. Taking Bedford with this provision, Dr. Prior compares it with Biggleswade, where a proper hospital has been erected, and he gives it as his experience that it is such a hospital which is needed for the Bedford urban and rural districts. And he gives force to his contention by showing his authority that Bedford is probably on the verge of another scarlet fever epidemic. Even if the two authorities referred to are not prepared at once to provide for the total needs of their two districts, they would do well to secure a proper site and make a commencement by erecting such an isolation pavilion as is shown in the recently issued diagram of the Local Government Board. And as they progress in this matter it would be well if they were to receive all infectious cases by arrangement with the General Infirmary, and enable the existing fever building to be utilised for the general purposes of the infirmary. Bedford had in 1886 a death-rate of 15·42 per 1000.

Kettering Urban District.—Mr. Dryland finds remonstrance with parents as to the impropriety of feeding infants with the food of adults quite useless, and this notwithstanding the fact that the practice leads to a waste of infant life which could easily be avoided. Some typhoid fever has occurred in connexion with polluted well-water, and apparently a difficulty is experienced here which is often felt elsewhere. It is not easy to ensure closure of wells unless pollution can be proved, but wells sunk in dangerous relationship with contaminating sources are often only intermittently fouled, and hence action has to be delayed until the evil which should be avoided has actually taken place. In this case water evidently producing typhoid fever could on certain occasions be found to pass as uncontaminated in the analyst's hands, and under such circumstances the owners of the wells, and even magistrates, are disinclined to believe that the negative evidence of the chemist is, in such cases, all but valueless. But we would counsel officers of health to support their action in such instances by making widely known in court and elsewhere the evidence published on this subject in Dr. Buchanan's official report a few years back. Good work is going on in Kettering as to the abolition of privies, the fitting of flushing apparatus to closets, the reconstruction of house drains, and the supervision of such establishments as slaughter-houses. A small outbreak of small-pox took place last year, but no recently vaccinated person was affected. The death-rate for 1886 was 17 per 1000.

Toxteth Park Urban District.—In this favoured suburb of Liverpool the annual death-rate for 1886 was 13·4 per 1000 on a population of some 17,500. The zymotic rate was somewhat higher than the average; the more fatal of the diseases in question having been measles, whooping-cough, and diarrhœa. Amongst the infectious diseases which were reported to Dr. Steeves there were 24 from scarlet fever, 14 from diphtheria, and 2 from typhus. These occurrences alone suffice to show the need for being prepared to isolate the first attacks, and the report states that during the year a site for a hospital was inspected by Dr. Thorne Thorne and General Carey, of the Local Government Board. The site is one in which the adjoining district of Wavertree is interested, and probably owing to the failure to secure united action between the two authorities delay is taking place in this important matter. In the meantime good sanitary work is in progress; dairies and bakehouses are inspected, and ashpits are subject to a weekly supervision.

Towyn Urban District.—In connexion with an outbreak of some fifty cases of scarlet-fever at Bryncrug, Mr. Groshols brings under the notice of his sanitary authority the more recent information as to the causation of this disease, but he is able to show that infectious diseases are by no means prevalent. In some respects the water-services would be improved if filtration and increase in quantity could be provided. Towyn drainage scheme unfortunately has fallen through, and certain parts of the town have to trust to cesspools. This town is one to which visitors are now attracted, and all its sanitary circumstances should be carefully looked into. At Aberdovey improvements in sewerage are needed; at Bryncrug water-supply and privies need attention; but, speaking of the district generally, much has been done in the interests of cleanliness. The general death-rate during 1886 was 17·9, and the zymotic rate 0·54, per 1000.

Brentford Urban District.—This district continues to make some trivial use of the Highgate and Islington-road Hospital for its infectious cases; but it is dangerous to trust to the accommodation there, for at any moment there may be none available. The zymotic rate was unusually high, this being mainly due to whooping-cough and measles; but at any time it may be some disease urgently calling for isolation, and hence Mr. Williams begs the authority to consider the needs of the district in this respect. Progress has been made as to sewerage and drainage in the district, which in 1886 had a death-rate of 18·9 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5426 births and 3641 deaths were registered during the week ending April 9th. The annual rate of mortality in these towns, which had been 23·5 and 21·6 per 1000 in the preceding two weeks, further declined last week to 20·5. During the last quarter the death-rate in these towns averaged 20·0 per 1000, and was 2·2 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 17·0 in Portsmouth, 17·1 in Birkenhead, 17·2 in Brighton, and 17·8 in London. The rates in the other towns ranged upwards to 25·4 in Sunderland, 25·9 in Cardiff, 28·0 in Oldham, and 32·6 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the eight preceding weeks from 340 to 471, further rose last week to 502; they included 250 from measles, 117 from whooping-cough, 41 from scarlet fever, 24 from diphtheria, 34 from "fever" (principally enteric), 33 from diarrhœa, and only 3 from small-pox. These zymotic diseases caused the lowest death-rates last week in Wolverhampton, Portsmouth, and Bolton; and the highest rates in Cardiff, Norwich, and Sunderland. The greatest mortality from measles occurred in Hull, Huddersfield, Oldham, Manchester, Norwich, and Sunderland; whooping-cough in Bristol, Huddersfield, Blackburn, and Cardiff; scarlet fever in Birkenhead, Blackburn, and Bristol; and "fever" in Birkenhead and Manchester. Of the 24 deaths from diphtheria in the twenty-eight towns, 15 occurred in London, 2 in Liverpool, and 2 in Oldham. Small-pox caused 2 deaths in Cardiff and 1 in Blackburn, but not one either in Greater London or in any of the twenty-five other large provincial towns. Nine cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease, including 8 which were admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 509 and 417 in the preceding two weeks, further declined last week to 363, and were 142 below the corrected average. The causes of 99, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Preston, Bolton, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Sunderland, Salford, Blackburn, Liverpool, Oldham, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 26·2, 25·9, and 23·5 per 1000 in the preceding

Digitized by Google

three weeks, further declined to 22·9 in the week ending April 9th; this rate exceeded, however, by 2·4 the mean rate in the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·6 and 15·8 in Perth and Leith, to 25·1 in Glasgow and 32·4 in Aberdeen. The 573 deaths in the eight towns last week showed a further decline of 15 from the numbers in recent weeks, and included 34 which were referred to measles, 33 to whooping-cough, 12 to diarrhœa, 11 to scarlet fever, 8 to "fever" (typhus, enteric, or simple), 4 to diphtheria, and none to small-pox; in all, 102 deaths resulted from these principal zymotic diseases, against 127 and 111 in the previous two weeks. These 102 deaths were equal to an annual rate of 4·1 per 1000, which exceeded by 1·3 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had been 55 and 43 in the preceding two weeks, further declined last week to 34, of which 21 occurred in Aberdeen and 13 in Glasgow. The 33 deaths from whooping-cough showed an increase of 2 upon the number returned in each of the previous two weeks, and included 11 in Glasgow, 9 in Edinburgh, 7 in Dundee, and 4 in Aberdeen. The 11 fatal cases of scarlet fever, of which 5 occurred in Edinburgh and 3 in Glasgow, exceeded the number in the previous week by 5. The 12 deaths attributed to diarrhœa showed a decline from recent weekly numbers, and agreed with the number in the corresponding week of last year.; 5 occurred in Glasgow and 3 in Edinburgh. Six of the 8 deaths referred to "fever" were returned in Glasgow, as well as all the 4 fatal cases of diphtheria. The deaths from acute diseases of the respiratory organs in the eight towns, which had been 152, 146, and 132 in the preceding three weeks, further declined last week to 110, but were 1 above the number in the corresponding week of last year. The causes of 68, or nearly 12 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 31·3 per 1000 in each of the preceding two weeks, declined to 30·0 in the week ending April 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 30·9 per 1000, the mean rate during the same period being but 17·8 in London and 19·4 in Edinburgh. The 203 deaths in Dublin last week showed a decline of 9 from the number returned in each of the preceding two weeks; they included 5 which were referred to measles, 5 to diarrhœa, 2 to "fever" (typhus, enteric, or simple), 2 to scarlet fever, 1 to whooping-cough, and not one either to small-pox or diphtheria. Thus 15 deaths resulted from these principal zymotic diseases, against 18 in each of the preceding two weeks; they were equal to an annual rate of 2·2 per 1000, the rates from the same diseases being 1·7 in London and 3·6 in Edinburgh. The fatal cases of measles showed a slight further increase upon recent weekly numbers, and those attributed to diarrhœa were considerably more numerous; those referred, however, to "fever" and scarlet fever showed a decline. The deaths of infants showed a further increase upon recent weekly numbers, while those of elderly persons had further declined. Four inquest cases and 2 deaths from violence were registered; and 62, or nearly a third, of the deaths occurred in public institutions. The causes of 25, or nearly 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon William O'Halloran is granted retired pay, with the honorary rank of Deputy Surgeon-General (dated April 13th, 1887); Brigade Surgeon William Cherry has been granted retired pay, with the honorary rank of Deputy Surgeon-General (dated March 28th, 1887); Surgeon-Major Daniel Charles Grose Bourns, from half-pay, to be Surgeon-Major, vice F. H. Welch, promoted (dated April 1st, 1887).

ADMIRALTY.—The following appointment has been made:—Mr. William Hunter, to be Surgeon and Agent at Rothesay.

James Booth Clarkson, L.R.C.P., &c., Surgeon Superintendent in Her Majesty's Government Emigration Service, has been transferred as Lieutenant from the 19th Lancashire Rifle Volunteers to the 3rd Battalion, Royal Fusiliers (City of London Regiment)—the old Royal Westminster Militia.

ARTILLERY VOLUNTEERS.—1st Banff: David Lechmere Anderson, Gent., to be Acting Surgeon (dated April 13th, 1887).

ENGINEER VOLUNTEERS.—1st Newcastle-on-Tyne and Durham: Acting Surgeon C. N. Lee, M.B., resigns his appointment (dated April 13th, 1887).—1st London: Sidney Reginald Dyer, M.R.C.S., Gent., to be Second Lieutenant.

RIFLE VOLUNTEERS.—4th Lancashire: Acting Surgeon W. M. Roocroft, to be Surgeon (dated April 13th, 1887).—2nd Oxfordshire: John Arthur Rigge, Gent., to be Acting Surgeon (dated April 13th, 1887).—1st Volunteer Battalion, the Princess of Wales's Own (Yorkshire Regiment): Charles Tweedy, Gent., to be Acting Surgeon (dated April 13th, 1887).

Correspondence.

"Audi alteram partem."

THE COLLEGE OF PHYSICIANS, THE COLLEGE OF SURGEONS, AND THE APOTHECARIES' SOCIETY.

To the Editors of THE LANCET.

SIRS,—From your admirable leading article in last week's LANCET, I collect that Mr. Berkeley Hill has enumerated "Dublin" amongst the "places of refuge for those who have been repeatedly rejected in London." So far as the College of Surgeons in Ireland is concerned, I give that statement an unqualified contradiction, and I challenge Mr. Berkeley Hill to support it with one single example. With respect to your observations as to the duties thrown upon the Medical Council in face of the present unfortunate condition of affairs, I fully endorse them, and that to such an extent that more than ten days ago, I sent a notice of motion for our forthcoming meeting of the General Medical Council couched in the spirit of your remarks.

Faithfully yours,

Dublin, April 12th, 1887. RAWDON MACNAMARA.

To the Editors of THE LANCET.

SIRS,—The President of the Royal College of Physicians stated the other day, at a meeting in reference to the union of the Apothecaries' Society with that body, that the College does not compete with the former corporation. I wish to ask if the chief design of the creation of the grade of Licentiates of the College was not of set purpose to compete with the Society of Apothecaries? I have the most distinct recollection of the fact that the chief argument used at the time of its creation was that it would rescue the future general practitioner from being called an "apothecary." Previously the Society of Apothecaries and the College of Surgeons of England qualified, and well qualified, the general practitioner, and I submit that we have gained nothing by the substitution of the name "Licentiate of the College of Physicians" for the name "Licentiate of the Society of Apothecaries." Neither of the corporations gives a qualification in surgery that is of the slightest value in the estimate of the profession; and if the examination for the licence of the College of Physicians were dropped to-morrow, we should not feel its loss, for I have yet to learn that either its curriculum or its examinations are stricter or better in any sense than those of the Society of Apothecaries. I rather think anyone, recollecting with myself the creation of this "Licentiate" of the College of Physicians, will not fail to see that not only has the College successfully competed with the Society of Apothecaries, but has passed up an order or grade of men who neither in status nor practice differ from the Licentiate of that body.

I am, Sirs, your respectfully,

April, 1887. M.D. LOND.

To the Editors of THE LANCET.

SIRS,—I feel somewhat apologetic in criticising any remarks of a gentleman so eminently distinguished as Mr. Berkeley Hill, but being one of those men upon whom his stigma of reproach has fallen, I am sensible of the honour

Digitized by Google

even of his contempt. I, for one, did not go up for the L.R.C.P. Edin. because I had failed in London. I have never presented myself at the London College, having had a higher diploma in view, although I was exempted from part of their first examination. Having obtained my M.R.C.S. (I may add without being ploughed), and wanting a medical qualification directly, I went to Edinburgh, where there is an examination for the licence every month. Does Mr. Berkeley Hill think that taking materia medica with the final examination, as at Edinburgh, does not add another element of risk; whereas in London that subject is taken separately? Secondly, I may add that if one does not pass on the paper work, one is not allowed to make up in the clinical and *viva voce* examinations. Thirdly, one has known cases of men who were proverbial for being lazy at their hospital, yet still pass their L.R.C.P. Lond., to the astonishment of their friends. No doubt this is so at Edinburgh, but it does happen in London also. Finally, does Mr. Berkeley Hill think that examinations are conclusive tests of ability? Would all well-qualified men be able to pass all their examinations again equally successfully? Is it not true that a man may not be able to localise a cerebral lesion, but be still a good physician? In conclusion, the vexed question of degrees and diplomas is a disgrace to our profession, and the sooner there is one and only one degree for every medical man in the kingdom, the sooner will good taste and brotherly feeling become the rule and not the exception. There are not a dozen degrees at the Bar. It is the work done that makes the man. Why should it not be so in the medical profession? I am, Sirs, yours obediently,

April 12th, 1887. M.A., M.R.C.S., L.R.C.P. Ed.

To the Editors of THE LANCET.

SIRS,—The sum and total of Mr. Davy's letter is, that the Apothecaries' Society should not be allowed a seat on the Conjoint Board, because by so doing they would perpetuate the idea that seems to exist amongst the profession of drugs occupying the first place in our treatment. I do not think an opinion formed upon so poor a ground will carry much weight with those who have to deal with the question. The subject has been well threshed out, but I ask you to allow me to mention a few points which seem to escape those of your correspondents who, while they sneer at the L.S.A. diploma, exalt that of the College of Surgeons.

1. If the standard of the Hall examination is so inferior, as is supposed by many, to that of other examinations, why does the College of Surgeons of London accept as equivalent to their examination in Medicine and Midwifery that conducted by the Hall, whereas the Scottish corporations do not accept it?

2. Some years ago the College of Surgeons granted their diplomas without examining in medicine. Are not those who possess such diplomas, and have not a medical qualification, quite as inefficiently qualified to practise as the L.S.A.'s?

3. And has it not been stated in the Medical Council that the standard of the examination of the Apothecaries' Society is equivalent to that of the College of Physicians, London, as ascertained by the examination visitors appointed by the Council?

Many suppose that the reason the Hall examination is not a fair test is because the time given to answer the written questions is so short that it is impossible to gain a fair idea as to the candidate's knowledge, whereas at the L.R.C.P. examination more time is given, and a better result obtained. I think the case is like an examination in algebra—the candidate who solved the most equations in the shortest time would be more successful than he who took the longest time. I may say that the corporations of Edinburgh conduct their examination much in the same manner as the London Apothecaries. Examinations are poor tests of knowledge, and no man should too highly praise his own diplomas or decry that of his neighbours. I submit, in the interests of the public and of our poorer students, who cannot afford a more expensive diploma, that the Apothecaries' Society will carry on the good work she has rendered to the profession hitherto, so that she will be able to write on her walls, "Tuta virtute mea."

I remain, Sirs, yours obediently,

April, 1886. JUSTITIA.

THE SURGICAL TREATMENT OF PULMONARY CAVITIES.

To the Editors of THE LANCET.

SIRS,—In the various modes of operative procedure referred to in Mr. Godlee's interesting lecture on the Surgical Treatment of Pulmonary Cavities, published in your issues of the 5th and 12th inst., an amount of injury to lung tissue is involved which is calculated to excite dismay in those whose experience of such formidable operations is limited, or who are mindful of the disastrous consequences which frequently follow even the most trivial wounds of the respiratory organs. The advantages of the simple and comparatively trifling operation of paracentesis thoracis, in cases similar to some of those described, do not appear to have engaged his attention, nor, as far as I am aware, that of any other surgeon of recent times who has specially studied the subject of pulmonary surgery. That such an operation would be attended with satisfactory results in cases where the tubercular process had reached the stage of formation of a cavity is shown by the history of the following case, the details of which I had the privilege of noting some years ago, whilst the patient was under the care of Professor D. C. O'Connor in the Mercy Hospital in this city.

T. K——, aged twenty-seven, admitted December 21st, 1881, stated that in the month of May of the previous summer, he had had a severe attack of hæmoptysis, in consequence of which he had attended the out-patient department of the hospital. A second attack of the same kind, two months later, obliged him to seek admission as an in-patient, and it was then found that he had lost considerably in weight since he first sought treatment. He was troubled by a severe cough, with night sweats; and under the right clavicle all the symptoms which indicate the existence of a pulmonary cavity were apparent. At the end of three weeks, during which the usual methods of treatment were adopted without influencing the course of the disease to any appreciable extent, an event of a remarkable nature occurred. One morning, whilst the patient was changing his position from the right to the left side, he suddenly experienced a sense of suffocation, attended by severe pain, which was referred to the right pectoral region. The dyspnœa rapidly abated, but the pain continued with varying degrees of intensity for two days. On examination it was found that the respiratory movements of the chest walls on the affected side were scarcely perceptible; percussion was markedly tympanitic all over the area of the pleural cavity; the respiratory sounds were altogether absent, and the patient could only rest comfortably in the dorsal position or on the right side. In fact, all the signs of a pulmonary cavity had disappeared, and their place was taken by those of a distinct pneumothorax. Subsequently the patient rapidly improved, and after an interval of a fortnight was discharged, in order to enable him to avail himself of an opportunity which offered of residing in a healthy country district.

In this case there can be no doubt that what happened was this. In the effort of making a change of position, an inspiration followed by closure of the glottis caused an unusual strain on the pulmonary tissue, which, together with the pleura pulmonalis, gave way at a weak point, allowing air to enter the pleural cavity and causing collapse of the lung. As a consequence of this occurrence, which may be regarded as a paracentesis thoracis from within, so to speak, the condition of the patient, as has already been remarked, underwent a considerable change for the better; and that this is what we ought to expect, a consideration of the pathological conditions established by the collapse will show. The presence in any organ, for physiological purposes, of a large quantity of blood creates in that organ an especial tendency to the inflammatory process, which has been recognised and admitted as the initial step in the commencement of many morbid phenomena, both those which have been identified as being due to the presence of a specific bacillus and those which have not yet been so identified. In the case of the lungs this tendency is much exaggerated by the highly venous condition of a great portion of the blood circulating in them. Nor is it necessary that the point of actual congestion should be reached in order to establish the danger. When collapse of a

Digitized by Google

tubercular lung occurs, this great volume of venous blood is excluded from the seat of disease; a pure and nutritious supply, comparatively free from effete material, is derived from the bronchial arteries, and thus an impetus is given to the process of repair which nature is continually striving to establish, even under the most adverse conditions. But it is not in the stage of disintegration alone that the beneficial effects of pulmonary collapse would be evident. In the earlier periods of tuberculosis, when the "deposit" exists in the form of an integral mass, it is readily conceivable that the cutting off the inflammatory blood-supply would have even a more powerful influence than in the later stages of the disease. The abnormal product would be strangled at the outset before the constitutional effects of the local lesion had reduced the general health below par, and thus a serious obstacle to the success of operative measures would be avoided.

There is another symptom in the phthisical series, the urgency of which should secure for the operation of paracentesis a favourable consideration at the hands of the surgeon. I refer to profuse and uncontrollable hæmoptysis.

Apart from the pathological points indicated, the effect of collapse in reducing the pulmonary circulation to a minimum is so evident that it is unnecessary to do more than refer to it. The operation, if carried out with a reasonable amount of care, and with proper antiseptic treatment of the warmed air admitted to the pleural cavity, ought to be free from danger, either at the time of performance or subsequently.

I am Sirs, yours faithfully,

F. E. ADAMS, M.D., M.Ch.,
Extra Physician to Cork Fever Hospital.

Camden Quay, Cork.

THE PULSE.

To the Editors of THE LANCET.

SIRS,—I have noticed that Dr. Broadbent suggests that irregularity of the pulse in mitral regurgitation may be due to the respiratory movements. Allow me to offer another suggestion in explanation, which occurred to me some time ago, and which I do not think I have seen mentioned anywhere. The regurgitant stream from the left ventricle, one would think, would generate a pulse wave in the pulmonary veins, which might be reflected back to the neighbourhood of the mitral valve. This might have its own rhythmical period, which would probably not agree with the rhythmical period of the action of the left ventricle. When certain parts of these two periods coincided, the regurgitant stream from the ventricle might be met and opposed by the reflected wave, and then more blood might be thrown into the aorta than at other times.

I am, Sirs, yours truly,

W. W. COLBORNE.

Margate, April 11th, 1887.

ON PUNCTURE OF THE ABDOMEN FOR EXTREME FLATULENT DISTENSION IN PUERPERAL CASES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 9th is the relation of an interesting illustration of the value of puncture of the abdomen for the relief of tympanites by Surgeon-Major Franklin, communicated through Dr. Priestley. He says: "The obstetric authorities—Playfair, Barnes, and Ramsbotham—gave him no help as to the way he was to relieve the extreme abdominal distension which was threatening the life of his patient"; so that after a consultation with Dr. Harris he punctured the ascending colon with a small trocar.

I am sure Surgeon-Major Franklin and Dr. Priestley will be gratified to learn that this treatment is fully discussed in the "System of Obstetric Medicine and Surgery" (vol. ii., 1885, p. 500) of myself and Dr. Fancourt Barnes in the following terms: "The treatment of tympanites is partly operative. The distress and danger attending tympanites are due in some measure to the great pressure from distension. This impedes respiration, circulation, and other functions. If the tension could be reduced, corresponding relief might be expected. Braxton Hicks advocated abdominal puncture with this intention (Obstetrical Transactions, 1868-69), and related cases in illustration. A small exploring trocar is the best instrument. By it the intestine is pierced in three or four of the most prominent points. As Hicks says, 'The pressure of the gas upon the sympathetic ganglia and nerves, and the tension of the tissues which they supply, add much to the collapse and vomiting. The least that can be claimed for the operation is that the last moments of the patient can be rendered comparatively free from suffering.' *We have adopted the plan, and can speak favourably of it.* It must never be forgotten that tympanites is not necessarily a fatal symptom; and it may well be that relieving this symptom may conduce to recovery."

Surgeon-Major Franklin's case bears happy confirmation to the truth of this observation.

I am, Sirs, yours faithfully,

ROBERT BARNES.

Harley-street, April, 1887.

PYREXIA.

To the Editors of THE LANCET.

SIRS,—In the paper of Dr. Maclagan on this subject I am much astonished at the criticism of Dr. Ord's paper. It seems that Dr. Maclagan has not quite grasped Dr. Ord's meaning.

It is now no new thought that the vital force is not a thing, but a state—a condition of delicate instability of organic compounds. These, assuming more stable conditions, liberate energy which, save in certain diseased conditions—e.g. delirium,—is not permitted to run wild, but is confined to definite channels and results. Here, then, are two processes: the raising of compounds from a stable to an unstable condition (analogous to the raising of a weight against the force of gravitation); and the opposite process—viz., the resolution of unstable into more stable compounds (analogous to the falling weight). Now, the principle of the conservation of energy applies everywhere, and in organic structures as in the purely physical world. What change of form of energy, then, has occurred during this raising of bodies to the sensitive instability of living tissues? This is Dr. Ord's question, it seems to me, and he replies thus: "This operation is the result of that form of energy called 'heat.' Heat disappears, and instead we find instability, or, as we may surmise, separation of atoms and molecules." In Dr. Maclagan's paper he states: "No evidence is adduced to support this. But there is much evidence, though chiefly on the physical side. Delicate tissue change, like all other change, can only result from other energy." The expression "absorption of heat" hardly expresses the actual physical process. The keynote of Dr. Ord's lecture is not absorption, but transformation. What was energy of motion (heat) becomes energy of position (the instability of higher tissue formation). In the building up of tissue day by day a large quantity of force must be required. If this building up cease, then this force is free, and escapes, as all force must, as heat. In fever tissue formation is lessened, and, unless disintegration be checked in proportion, heat must result. To regard heat as an excretory product is word-play. It is produced during retrograde tissue metamorphosis, but is not a product. In a similar way the remarks about the experiments on cucumbers are not to the point. The same processes occur in the animal as in the vegetable world, although the tissue changed may differ.

Dr. Ord's position is well based, not only physiologically, but physically. He points out the process of tissue formation and disintegration, although admitting that we do not know what is the controlling element. This check to tissue change is the secret of life; it is that which differentiates living from ordinary physical substances.

I am, Sirs, yours faithfully,

F. W. BENNETT, M.D. Lond.,
Assistant-Physician to the Leicester Infirmary.

DEGREES FOR LONDON STUDENTS.

To the Editors of THE LANCET.

SIRS,—It is a matter of deep regret that the plan for a united action on the part of University and King's Colleges, together with the two Royal Colleges, to form the new University of Westminster, and thus jointly to apply for a charter, was not proceeded with. For this scheme would apparently have solved most of the difficulties that at present surround the question of degrees for London students and that of a teaching university. It is most desirable that

Digitized by Google

the Charter should be obtained before October next, otherwise our London hospitals will have still fewer entries; indeed, a parent would be undoubtedly to blame if he did not so arrange his son's professional education as to enable him to get a degree after honest work. It is trying enough now for capable practitioners to hold their own against the crowds of Scotch and Irish graduates, but this competition will get still severer for the London student every year unless something is promptly done to give him an equivalent title.

I am, Sirs, your obedient servant,

April 12th, 1887. A PARENT.

THE RIVIERA IN 1887.

THE EARTHQUAKE.—MONTREUX.—LES AVANTS.

(By our Roving Correspondent.)

THOSE who, year after year, leave England for more genial climates have had strange experiences this season. Many no doubt who have encountered the severe trial of the earthquakes in the Riviera have thought that there is much truth in the refrain that "there is no place like home," and hundreds have sought refuge in the congenial spring of Great Britain from the worry and anxiety which necessarily surrounded all who found themselves in the unhappy district upon which such great calamities have come. Earthquakes, however, are not of every-day occurrence, and not easy to avoid, for we know that our own island is not altogether free from them, as the country near Colchester testified some three years since. The Riviera will be more or less empty for this season at least, but there is little doubt that its bright sun and lovely scenery and foliage will prove attractive enough to outweigh the unpleasant memories of February, 1887, and that in a year or so the normal and well-deserved popularity of the district will be restored. There is a silver lining to every cloud, it is said, and we may hope that the earthquake may bring some compensation to those who seek health and relaxation in the south of France. Many of the hotels have been rudely shaken, some few so severely that they will have to be rebuilt. When the repairs are undertaken, it is to be hoped that the proprietors will not be content with mere patching and a delusive hiding of dangerous cracks by a superficial daubing with untempered mortar. There is no doubt that many hotels have been "run up" at a great pace, and there is equally no doubt that many of them are thoroughly bad, both in design and workmanship. A sojourn in almost any of the hotels in the south of France is sufficient to show how flimsy are the parti-walls, which are often constructed of one layer of thin hollow bricks placed on edge, the surface being daubed with mortar. These parti-walls have no struts of timber running through them, and it is not to be wondered at that when the houses began to shake these flimsy divisions quickly broke, and fell on this side and that. These hollow brick partitions are excellent conductors of sound, and the occupant of any one room can generally hear through the wall the intimate conversation of those who inhabit the rooms on either side of him. Light sleepers are often unable to get their much-needed rest until their neighbours have gone to bed; and if they do not luckily fall asleep in the brief period which elapses between the talking and snoring of some Teutonic Stentor, an almost sleepless night is the consequence. Hotel proprietors must be made to know that quiet and rest are as important for invalids as are the quality of the food and air, and the parti-walls between the rooms in the hotels should be sufficiently solid to exclude sound and withstand the really moderate amount of vibration to which many have been subjected this year and may be again. The doors of communication between rooms and between rooms and corridors should in all cases be double, for the purpose of excluding noise. I have dwelt on the importance of this matter in previous letters, and no excuse is needed for again drawing attention to it. Speaking from a professional point of view, it seems most important that invalids should not be allowed to stop in any hotel where they cannot command rest and quiet at any hour they please.

Hotel staircases again demand attention. Most of the staircases in the south of France and Italy are of a kind which must be dangerous in case of fire or earthquake. Constructed, as they often are, of thin slabs of marble, supported on one side only, each step getting its outside support merely from the step below, it is obvious that if one step be cracked by fire or vibration and be shaken from its position, the whole structure is in great danger of coming down "with a run." This actually happened in many houses during the late earthquake, and it is to be hoped that during the work of reconstruction this important matter will be attended to. Architects are very prone to make a great feature of the staircase; and there can be no doubt that when travellers from the North, accustomed to narrow, steep, wooden stairs, are ushered into an hotel, and see before them a broad staircase of easy gradient, with steps of pure white marble running upwards in ten or a dozen flights, their minds are startled by the unaccustomed and palatial magnificence. The danger of such staircases, however, is often directly proportioned to their height and breadth, and we may hope that we have seen the last of them. Such staircases are often very undesirable channels for noise, and not unfrequently the smell of the kitchen ascends by them and pervades the whole house. Staircases should be constructed so that the steps are supported on both sides by walls, and if so constructed they would be comparatively safe in case of accident. In large hotels two staircases of moderate dimensions are better from every point of view than one, be it ever so broad and palatial in design. The staircases, kitchen, and sanitary offices should always be in a structure more or less distinct from the rest of the building, and thus the parts of the house devoted to living rooms would run no risk of being pervaded with air from kitchens, closets, or sinks. It need not be said that in the reconstruction of hotels what may justly be called the "unsanitary offices" will need to be remodelled. All sanitarians admit that in a water-carriage system of sanitation imperfectly carried out we have the very demon of pestilence, and foreign hotel keepers need to be reminded that a sprinkling of some carbolised powder and the use of a brush are no compensation for half-inch supply pipes, faulty traps, and no ventilation. It may be laid down as an axiom that a closet which stands in need of a brush and disinfectants must be a perpetual source of danger in a house, and travellers should be well aware of this fact before selecting a house in which to make a long sojourn. The introduction of water-carried sewage along the coast has made the foreshore unpleasant in many places, and those who walk upon the beach to get a "sniff of the briny," sniff a good many other things which are neither savoury nor sweet. It is needless to say that with the rapid increase of population the sewage evil is increasing, and must increase; and I have little hesitation in predicting that that locality which can find some means of efficiently treating its refuse other than washing it into the the sea will experience a rapid rise in popularity. The water-supply is for the most part above suspicion, and is obtained from sources high up in the Alpes Maritimes. The Nice Water Company supplies excellent water, not only to the city of Nice, but to other towns near it.

It may not be uninteresting to your readers to place upon record, now that the excitement of the catastrophe is overpassed, the actual experience of one who felt the earthquake in full, though not its fullest severity. He was located *au troisième* in an hotel standing on one of the highest points of the rock at Monte Carlo. After a lovely day, in which a powerful sun had been shining in a cloudless sky, he retired to rest. The noise of persons returning late from the carnival caused the night's rest to be a good deal disturbed. The final disturbances occurred at a few minutes before six, when he was awoke by a noise above, below, and on either side, which, on reflection, seems to be best likened to the labouring of ships at sea, and was doubtless due to the breaking of the various materials of which the house was built. The bedroom was distinctly rocking, and his first instinct was to jump out of bed to avoid rolling out. In a few seconds the house steadied, and then the mental question arose as to the cause of this rude disturbance. The window commanded the Bay of Monaco with the old town opposite and the district of La Condamine below lying between Monte Carlo and the old town. Looking out, the commencing colours of a glorious sunrise met the gaze, and from the old town, and from La Condamine, some 200 feet below, there arose a babel of voices of persons, doubtless inquiring of each other what was the matter. With the voices was intermingled the barking of innumerable dogs, that had been apparently as much surprised and startled as their owners. These facts made it apparent that

Digitized by Google

the disturbance had affected the whole locality, and a shock of earthquake seemed the only reasonable solution of the phenomena. Under the circumstances, it seemed advisable to get up (further sleep was certainly impossible, and the morning was tempting enough to call one from one's bed under any circumstances). Just as a rather hurried toilet was drawing to a close the second shock occurred, not so strong as the first, but only too distinct and most unpleasant, causing the house to creak and the windows to sway. Downstairs and into the open as quickly as possible seemed the reasonable course, for it is obvious that a house cannot stand many shocks such as we experienced, and it might happen that a third would cause it to give way. All the world was up and in the streets, the toilets being most peculiar and imperfect. Being up, what was to be done? It is difficult to know what can make one feel so utterly powerless as a shock of earthquake. No human power can prevent it; and when you have sought the open air, you have done all that is possible in the way of avoiding the possible consequences of further shocks. I have seen it stated in many of the papers that a condition of "panic" prevailed, but to this I should demur. Certainly I saw none, neither at Monte Carlo nor (later in the day) at Nice. That persons should get into the open air as quickly as possible was reasonable, and was distinct evidence of cool thought rather than panic. The question as to the cause, direction, &c., of the shock was naturally discussed, and when many persons discuss at once there is noise, but certainly there was no shrieking, and throughout the day I saw only one young girl who had "fainted," but as the colour of her cheeks was good, I concluded that she was merely "taking on," to use a common expression. The population of Monte Carlo is Franco-Italian, and might be assumed to be impressionable and excitable, but certainly they treated this unfortunate occurrence with the greatest *sangfroid*—a fact which made me suspect that this shock was a thing concerning which they were not without previous experience.

The amount of material damage sustained by the buildings at Monte Carlo was singularly small. The swaying of the houses had been sufficient to stop the clocks, but beyond this ominous fact there was little external evidence of the strain to which the buildings had been subjected. In the low-lying La Condamine, between the rocks of Monaco and Monte Carlo, there was more evidence of external damage, but even here the evidence was limited to a few fallen parapets and chimneys. In this part of the town the buildings are not so high, few being more than two or three storeys, and yet it was evident that these comparatively low houses had suffered more than the huge caravanserais perched on the rock of Monte Carlo. From facts which came to light subsequently it appeared that Monaco as a whole had suffered less than Mentone on the east and than Nice on the west. Mentone, being nearer to the centre of disturbance, might be expected to suffer more than Monaco; but Nice being further from the centre, ought, at first sight, to have suffered less. The reason, apparently, for the comparative escape of Monaco lies in the fact that, with the exception of La Condamine, the houses are built directly on the solid rock, while at Nice and Mentone a large proportion of the buildings are upon the alluvium which has been carried down by the torrents which intersect these cities. The trembling of the earth would cause more movement in the loose alluvium than the solid rock, and hence houses on the alluvial ground seem especially to have suffered.

An interesting point in connexion with the catastrophe was the difficulty in obtaining any accurate information as to the extent and severity of the trouble; in fact, it was not until the arrival of the English papers that the real facts became known. On inquiry at the telegraph office one learnt that the shock had been felt "all over France." It was said that Grasse was in ruins, that the shock had been terrible at Marseilles, and that a church had fallen at Mentone &c. In estimating the value of the current reports, it is needless to say that great allowance had to be made for the natural desire of hotel proprietors &c. to retain their guests, and to impress upon travellers that by moving in any direction they would be going out of the frying-pan into the fire. The fact of most value which enabled a judgment to be formed as to the probable focus of the disturbance was the blocking of the telegraph wires to the east, while they remained open to the west.

(To be concluded).

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY OF EDINBURGH.

AT the approaching graduation ceremonial, the Senatus Academicus have decided to confer the honorary degree of LL.D. upon Professor von Kölliker, of Wurzburg. The degree was offered him on the occasion of the tercentenary celebrations, three years ago; but he was prevented from being present at the time. The degree is now to be conferred *in absentid*, as Professor Kölliker's feeble state of health precludes the possibility of his travelling such a distance at the present time.

PROPOSED UNIVERSITY HALL.

A need has of late been growingly felt in Edinburgh to provide the possibility of a more corporate and social college life for the students of the University than has up to the present obtained among them. With this view an association has now been formed, with Sir William Muir, Principal of the University, as its president, which will undertake the establishing of a number of halls of residence for the students as occasion seems to demand. A beginning has been made by securing a convenient block of buildings near the University buildings and the infirmary; these premises are to be prepared for the reception of students in the coming summer session. Rents of rooms are to be adjusted so as merely to cover expenses, and it is stated that desirable rooms are attainable at from 7*s.* 6*d.* to 15*s.* weekly by students anxious to join the colony. It is desired by the promoters of the scheme to combine some beneficial influence on the surrounding districts with the ordinary avocations and studies of the inmates of the hall; and it is stated that students interested in such work as is done at Toynbee Hall, London, by Oxford and Cambridge students, will obtain preference for their applications for entrance. Out of a total of 3500 students, it is probable that a sufficient number will be forthcoming to fill this hall, and possibly another should the first experiment be successful. If carefully managed its success is assured, and its establishment probably marks an important point of departure in our academic institutions.

THE FEVER EPIDEMIC.

The epidemic of scarlet fever dies out slowly, and the City Fever Hospital is still crowded with inmates. The report for the present week shows that of 244 cases in the wards 200 are cases of scarlatina.

CLINICAL INSTRUCTION IN FEVERS.

As the outcome of strong representations to the city authorities some months ago, it was decided to open the wards of the City Fever Hospital for the visitation of students; and a system of clinical instruction was inaugurated by Dr. Allan Jamieson, the visiting physician of the institution. The results up to the present have been highly satisfactory, and Bailie Russell, to whose efforts this improvement is largely due, was able to report recently to the Town Council that twenty-six students and four medical graduates had availed themselves of Dr. Jamieson's teaching during his first course of lectures, and that none of those attending had taken fever.

EDINBURGH UNIVERSITY COURT.

At its last meeting the Court confirmed the arrangements approved by the Senatus, under which Professor Haycraft, of the Mason College of Science, Birmingham, will take charge of the department of Physiology and superintend the teaching of the practical classes during the coming summer, in the absence of Professor Rutherford. The arrangements include the payment of £200 to Professor Haycraft by the Professor of Physiology.

THE NEW EXPERIMENTAL LABORATORY.

The new laboratory established by the Edinburgh Royal College of Physicians has already commenced its objective existence. A very convenient building, in close proximity to the infirmary and the medical schools, has been acquired, and will shortly be supplied with all the modern requirements of an experimental laboratory. The directorship of the new institution has not yet been filled up. Applications for the post were received by the committee in charge up to the end of last week, and it is anticipated

Digitized by Google

that the result of their deliberations will be shortly announced. Application has been made entirely by private letters addressed to the chairman of the Electing Committee, and testimonials have not been received on behalf of any of the candidates. Owing to the conditions of the contest, it is not definitely known how many competitors are in the field; but the names of Dr. Sims Woodhead, Dr. William Hunter, and Dr. Noël-Paton are mentioned as probably successful candidates. If these gentlemen are really among the competitors, the College has cause for congratulation in the *embarras de richesse* thus placed at its disposal; although the strong claims of each, based on the valuable work they have already accomplished, will make the decision a difficult one. The first task of the director, when appointed, will be to superintend the thorough equipment of the laboratories; subsequently his duties will chiefly consist in advising suitable lines of research and in organising the daily duties of his department. The laboratory and its success are the objects of great interest in Edinburgh, and there is every prospect that the new institution will form a useful channel through which the pent-up scientific energies of the school may freely develop themselves.

THE RECTORSHIP OF EDINBURGH UNIVERSITY.

The Marquis of Lothian, K.T., has been chosen by the University Conservative Association as their candidate for the Rectorship of the University, vacant through the death of the late Lord Iddesleigh. The date of the election is still nearly six months distant, but the Association is desirous of losing no time in placing their candidate before the constituency of undergraduates, and in conducting an active canvass in his behalf.

During the last six months a sum of £2750 has been received for the Royal Infirmary in the form of legacies.

Edinburgh, April 12th.

ABERDEEN.

(*From our own Correspondent.*)

THE CITY HOSPITAL.

After a long and careful inquiry into the burning of a patient at the City Hospital, the Public Health Committee have issued a report, in which they state that they "are of opinion that the head nurse acted wrongly in placing the ward maid, Margaret Easton, in charge of the patient, knowing that Easton would be obliged to leave her several times quite alone for a period of from twenty to thirty minutes; they are further of opinion that the head nurse failed in her duty in not taking steps for securing a proper complement of nurses." It is also stated that, "in the opinion of the committee, it is matter of regret that the medical attendant did not report the occurrence earlier, and that after the accident took place he did not consider it requisite to visit the patient more frequently than once a day." The head nurse has sent in her resignation, which has been accepted. At a meeting of the Town Council, it was agreed, on the motion of the Lord Provost, to ask Surgeon-Major Fassor, superintendent of the Edinburgh Infirmary, to visit the hospital and report "as to what changes and improvements should be introduced for the purpose of placing the institution in a thoroughly efficient and satisfactory condition."

THE ROYAL INFIRMARY.

At a special meeting of the Committee of Management, held on the 8th inst., the Plans Committee submitted a revised design for the extension and improvement of the infirmary buildings. According to the proposed plan, the new building would accommodate 233 beds, with a cubic space of 1400 feet per bed. The approximate cost of the new design is £30,890. The "Jubilee Fund" now amounts to nearly £19,000.

ABERDEEN UNIVERSITY.

The last of the "professional examinations" took place to-day at Marischal College, and the graduation ceremony takes place on Friday, the 15th inst. The summer session commences on the 25th, and the preliminary examinations are to be held on the Friday and Saturday preceding. At a meeting of the Senatus held on the 2nd inst., Dr. Cash, recently appointed to the Chair of Materia Medica, was duly installed. At the same meeting it was resolved to provide an album for the purpose of receiving the signature of every student at matriculation and graduation. To-day's *Aberdeen Journal* says that "some correspondence has taken place recently between the University authorities and the Government with reference to a grant in aid of the extension of the University buildings. The sum needed to carry out the scheme is £84,000, and of this sum one-fourth was proposed to be raised locally. Information has been received that under existing circumstances (the smallness of the local efforts) the Lords of the Treasury cannot meet the wishes of Aberdeen."

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

Dr. McKenzie Booth has been elected librarian in room of the late Dr. William Fraser, and Dr. John Gordon succeeds the late Dr. Beveridge as treasurer to the Society.

Aberdeen, April 12th.

DUBLIN.

(*From our own Correspondent.*)

THE QUEEN'S JUBILEE.

SIR WILLIAM STOKES, President of the Royal College of Surgeons in Ireland, has issued cards for a dinner in celebration of Her Majesty's Jubilee. The banquet, which will be held in the College on Saturday, the 23rd inst., is expected to be a magnificent success, and will be attended by his Excellency the Lord-Lieutenant, his Serene Highness Prince Edward of Saxe-Weimar, the leading medical men in Dublin, and many others holding high official positions.

PROPOSED HOSPITAL FOR CONSUMPTION NEAR DUBLIN.

A subcommittee has been appointed by the Executive Committee of the City and County of Dublin Jubilee Committee, in order to select a suitable site for the proposed institution, and ascertain the cost of erecting the same, to provide accommodation for about twenty-five beds. Lord James Butler, the chairman of the Managing Committee of the Adelaide Hospital, has urged the necessity of establishing a convalescent home in connexion with that hospital, to be styled "The Jubilee Victoria Convalescent Home," under the same management, and has initiated the movement by a gift of £50.

UNIVERSITY OF DUBLIN.

The authorities of Trinity College, Dublin, by desire of Her Majesty, have arranged to allow credit for the Trinity Term examinations to all students, except candidates for the degree of Bachelor of Arts, whose names shall be on the College books at the dates fixed for their respective examinations.

NIGHT LECTURES.

The Standing Committee of the Royal University of Ireland on March 31st last adopted a resolution, to the effect that after that date certificates of night lectures would be refused by the University. This announcement came as a very disagreeable surprise to many hard-working students, who from no fault of their own may be prevented from attending day lectures; and, unless this objectionable rule is rescinded by the Senate, they will become ineligible for the next examinations of the University. The writer of this has lectured for some years to both day and night students, and can conscientiously state that for anxiety to learn, steadiness, and general good conduct, night pupils are in no way inferior to those attending the day classes. If the Senate enforce the carrying out of this resolution, a serious injury will be inflicted on a large and deserving class of medical students.

A bazaar and fancy fair in aid of Sir P. Dun's hospital will be held next week at the College of Physicians.

Dr. J. W. Swan died, on the 8th inst., at Clarinda Park, Kingstown, aged eighty-four years.

Dublin, April 12th.

NEW HOSPITAL IN WEST RENFREWSHIRE.—At a special meeting on the 7th inst. contracts were accepted for the erection of a combination hospital for the parishes of Houston, Kilbarchan, Erskin, and Inchrinen, including the burgh of Johnstone. The cost will be under £2000.

PARIS.

(*From our own Correspondent.*)

M. PASTEUR'S METHODS.

On the 20th of last July a man named Hamyau, of Dunkirk, was bitten by a dog. On the 20th of the following month the same dog, at that time probably rabid, bit another man, who was forthwith sent to Paris and subjected to the intensive treatment. His death from paralytic rabies formed the subject of M. Peter's first communication to the Academy. Hamyau, who six months ago was a strong, vigorous man, is now suffering from a strange illness, which those favourable to M. Pasteur's treatment affirm to be pulmonary congestion. M. Peter, on the other hand, does not hesitate to declare that the symptoms are due to *canino-experimental* inoculation. Since the middle of February there has been paresis of the lower limbs and of the organs supplied by the pneumogastric nerve. The breathing is constantly oppressed, the pulse remains at 120, and the abdomen is tympanitic. Pressure made by M. Peter on the vagus gave rise to alarming dyspnœa and palpitation. The patient seldom passes a day without feeling neuralgic pains at the seat of the inoculations, but no abnormal sensation is felt in the scar of the bite. The symptoms have been somewhat relieved by the administration of pilocarpine in doses of fifteen grains daily, but M. Peter considers that the case will terminate fatally.

INOCULATION AGAINST PORCINE MEASLES.

A provincial paper relates another mishap, which is not uninstructive. A veterinary surgeon had been supplied with the preservative against porcine measles, and inoculated a herd of swine belonging to one of his clients. Unfortunately the pigs died, and the veterinary inoculator was obliged to reimburse their owner. The *Echo du Midi* says that he is about to bring an action for recovery against M. Pasteur.

PROPHYLAXIS OF YELLOW FEVER.

MM. Freire, Gibier, and Rebourgen presented a note at the Academy of Science on the Prophylaxis of Yellow Fever by the Inoculation of an Attenuated Virus. In 1885 and 1886, 6524 persons submitted themselves to this protective vaccination in Rio Janeiro, and during this period the total number of deaths from yellow fever was 1675. Of the victims 1667 had not been inoculated, the mortality amongst those protected amounting to eight deaths only. The authors state that, taking as the basis of their calculation the population exposed to the contagion, the percentage of deaths for the whole number was 1 per cent., whereas for those who had been subjected to preventive inoculations it was only 1 per 1000.

THE SLEEPER OF THENELLES.

The *Revue d'Hypnotisme* contains a report by Dr. Edgar Bérillon on *la Léthargique de Thenelles*, a young woman who will shortly have accomplished the fourth year of an uninterrupted trance. Miss M. B——, now twenty-five years of age, has always been sickly, delicate, and nervous. On May 30th, 1883, after a fright, she had several convulsive attacks, and then fell into a profound sleep, from which she has never awakened. She is kept alive by small quantities of liquid food, which are swallowed automatically. The excretions are greatly diminished, and menstruation is now entirely suppressed. When examined by Dr. Bérillon, the limbs were found to be much wasted, and all trace of adipose tissue had disappeared. Anæsthesia is complete, and the knee reflex is abolished. The pulse is almost imperceptible, and gives 100 beats to the minute. Respiration is regular, but feeble. The breath has not the autophagic odour of insanity and starvation. The face is pale, waxy, and without expression. The mucous membranes are colourless. When the eyelids are opened the eyes are seen to be convulsed upwards, and blowing upon them produces no palpebral reflex. The jaws are tightly closed by contracture of the masseters. The arms can be easily raised, but enter at once into contracture. The muscles are in that state known as neuro-muscular hyper-excitability, and the slightest touch or puff suffices to cause contracture, which can be removed by the application of warmth. Besides the sensory anæsthesia there is complete mental inertia, and the patient is inaccessible to any kind of hypnotic suggestion.

Paris, April 12th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a quarterly meeting of the Council held on Thursday last the minutes of the last meeting were confirmed. On the recommendation of the Museum Committee, it was determined to purchase a very fine specimen of the egg of the Epiornis.

Mr. James Berry, of 60, Welbeck-street, was awarded the Jacksonian Prize for his essay on "The Pathology, Diagnosis, and Surgical Treatment of Diseases of the Thyroid Gland."

The seventh report of the Committee on Charters and Bye-laws containing the draft of the new supplementary Charter to give effect to several alterations in the Charters agreed to by the Council, was approved and adopted, and it was resolved that the necessary proceedings be taken to submit the same to the Privy Council.

The resignation of Mr. Howse as Examiner in Anatomy was accepted.

Permission was given to the President to hold a private conversazione in the College in June next.

The Council having taken exception to the mode of advertisement of a Member, and he having sworn before a magistrate to cease from such practices, the Council agreed not to take further proceedings in the matter.

The proposal of the Committee of Delegates having been approved by the College of Physicians, authority was given to the delegates to erect a statue of the Queen in the Examination Hall, at the joint expense of the two Colleges.

It was referred to the President and Vice-Presidents to prepare an address of congratulation to Her Majesty on the completion of fifty years of her reign. Further memorials (one of them from Scotland) against the proposal from members of the medical profession and men of science to found a laboratory for the prosecution of pathological and physiological research were presented.

A resolution, proposed by Mr. T. Smith, was carried *nem. con.*—viz., "That a professional auditor be appointed to audit annually, in association with the committee of auditors, the College accounts."

Sir James A. Hanbury, K.C.B., of the Army Medical Staff, was elected a Fellow of the College, under Section 5 of the 15th Victoria, applicable to Members of twenty years standing.

Obituary.

CHARLES HUTTON, M.D. ST. AND., M.R.C.P.

DR. CHARLES HUTTON, late of 26, Lowndes-street, Belgrave-square, long engaged in the practice of obstetric medicine, died on the 27th of last month, after a short attack of acute bronchitis, at the age of sixty-nine. Dr. Hutton had for some time been in failing health; his last illness was apparently the result of a cold caught while employed on an errand rather of charity than duty on the night of March 13th.

Charles Hutton, M.D. St. And., was the youngest surviving son of the late William Hutton, Esq., of Beetham and Overthwaite, in the county of Westmoreland. The family was an old one, the property having descended from father to son for upwards of 300 years. Dr. Hutton studied at St. George's Hospital and Paris, and shortly after the completion of his studentship married in 1850 a daughter of the late Dr. Seymour, then one of the physicians of St. George's Hospital. This lady survives him with a son and two daughters. For many years Dr. Hutton was physician to the Hospital for Children and Women, Waterloo-bridge-road, and to the General Lying-in Hospital, York-road, Lambeth. During his long professional career he won the affection and esteem of all who knew him. He was a man of unblemished honour. He was most unselfish in all his proceedings, ever sympathising with and striving to relieve suffering, whether among rich or poor, regardless of his own profit or advantage. His patience and devotion were unwearied, and a wide circle of professional and private friends will sincerely lament his loss. Dr. Hutton was of a retiring nature, and, though of acknowledged skill in his special department, was

Digitized by Google

not successful enough to be able to leave a provision for his family. His long, honourable, and laborious life appears to have been inadequately rewarded. It is not impossible that some attempt may be made to relieve in some small measure the necessity of Dr. Hutton's family.

PIETRO CIPRIANI.

A PHYSICIAN and citizen of the first order has just been lost to Italy in the Senator Pietro Cipriani, who died at Florence on the 4th inst., in the seventy-ninth year of his age.

Born in San Piero a Sieve on Dec. 10th, 1808, as a boy he gave early indications of future distinction, and at the age of eighteen began his medical curriculum at the University of Pisa. He took the degree of Doctor in Medicine in 1832, and next year repaired to Florence for better means of clinical observation and research. He soon displayed remarkable skill in diagnosis and treatment, which led to his appointment as assistant-physician to the Florentine Hospital. This post he filled with increasing acceptance till August, 1835, when the cholera explosion at Leghorn summoned him thither to take charge of the lazaretto specially set apart for sufferers from that disease. His devotion to his heavy and hazardous duties was such that at the disappearance of the malady he was publicly thanked by the municipality; while the gratitude of the entire population towards him took the form of a gold medal struck in his honour.

Fresh from the cholera wards at Leghorn, he was welcomed back to Florence by the heads of the profession, and he became assistant in the Clinica Medica Generale to the illustrious Maurizio Bufalini. So highly did Bufalini estimate his clinical and expository powers, that on the frequent occasions when he had to be absent as a consultant, he delegated to young Cipriani the duties of the day in the ward and the lecture-room. Meanwhile, in great measure due to the rigid inductive teaching of Bufalini, medicine throughout Italy, and especially in Tuscany, was making signal advances, one effect of which was to separate from the general clinic such diseases as had asserted their claim to distinct and special consideration. Skin affections were one of these, and for the chair of "Malattie Cutanee," created for the first time in Florence, no fitter occupant was found than Cipriani, who, however, before entering on its duties, took care, with characteristic modesty and thoroughness, to qualify himself by a diligent course of study at the renowned dermopathic clinics of Vienna and Paris. It was in 1840 that Cipriani delivered his first course of lectures on the "Malattie Cutanee," and such an interest did he throw round his specialty that students from all parts of Italy came to listen to his prelections. He was not destined, however, to close his career in dermatology simply; for on the veteran Bufalini having, from age and ill-health, to resign his post at the head of the Florentine "Clinica Medica," Cipriani was selected as one of the only two Tuscan physicians who were worthy to take up the torch of the master. The duties that now devolved on him were arduous and complicated; but all difficulties faded before his chivalrous sense of honour, his indefatigable application, and his admirably disciplined powers.

He was too active a practitioner and too fastidious a writer to publish much; but as president of the Medical Faculty of the Florentine Institute he signalised himself as a sound critic and man of taste, and guided others to the path of authorship from which he shrank himself. In 1879 his health began to decline, and it was only after reiterated appeals to be relieved of his official duties that he was allowed to limit his activity to consultations merely. He continued, as Emeritus Professor and as occasional Assessor at the directing Council of the Florentine Institute, to give the profession the benefit of his experience and judgment, while his devotion to good works kept him to the last the chief promoter of the Blind Asylum of Florence. Sometimes, too, he would appear in Rome during great political crises and take his part as Senator in the deliberations of the "Patres Conscripti." But within the last few years the decline of health, the death of familiar friends, and not a little domestic affliction, withdrew him more and more from the public view, so that it was with much less surprise than sorrow that on the 5th inst. Italy received the news of his death.

JAMES BARRON, B.A., M.D.

IT is with sincere regret we have to announce the death of Dr. Barron, of Belfast, which took place at his residence in that city on the 2nd inst., under very sad circumstances, he having succumbed to typhus fever, a disease which has carried off so many Irish medical men, and which he contracted from a dispensary patient whom he was attending. Dr. Barron, who was a native of Antrim, was educated at the Belfast Medical School. He graduated in the Queen's University, and at his M.D examination was awarded a first class and the gold medal. Shortly after receiving his diploma he was appointed dispensary doctor at Templepatrick; but, being of an ambitious nature, he went to Belfast, and was elected house-surgeon at the Royal Hospital, a post which he held for several years, until, a vacancy having occurred in the surgical staff, he was appointed assistant-surgeon. He then began private practice in Belfast, and shortly afterwards resigned his hospital appointment on being chosen to take charge of one of the dispensary districts, an office which he held up to his decease. He was secretary of the Ulster Medical Society, and a short time ago was elected a member of the staff of the Ulster Hospital for Women and Children. Dr. Barron was thoroughly versed in all branches of the medical profession, and being a man of the most kindly disposition he was extremely popular with his brother practitioners, as well as with a large circle of patients and friends. It is melancholy to think that within a short interval two medical men in Belfast, living in the same district—Dr. Wadsworth and Dr. Barron—have both fallen victims to typhus fever. An immense number of medical men and other friends were present at the funeral, to show a last mark of respect to one who had become so deservedly popular.

G. BACON SWEETING, M.R.C.S., L.R.C.P. LOND.

THE death of this gentleman took place on March 23th, at Great Smeaton, in Yorkshire, where he had gone in search of health. For upwards of thirty years he occupied a prominent position in the profession at King's Lynn and the neighbourhood. Born at Bridport in Dorsetshire, on March 26th, 1824, he was apprenticed to his father, Mr. William Sweeting, himself a practitioner of considerable repute. After studying at University College, and subsequently in Paris, he entered the profession by taking the membership of the College in 1848. For some years he was engaged with Mr. Image, of Bury St. Edmunds, in active practice. In 1856 he went to reside at King's Lynn, and at once took a foremost place in the profession. Although engaged in general practice all his life, his opinion and aid as a consultant both in medical and surgical cases were constantly sought by his brother practitioners. The trust they thus bestowed in him was never betrayed, and so he succeeded up to the time of his death in successfully filling the difficult position of a consulting general practitioner. For a short time he was surgeon to the West Norfolk and Lynn Hospital, but finding the tax on his time too great, he retired, and was appointed consulting surgeon. He was a Fellow of the Royal Medical and Chirurgical and Chemical Societies. Of imposing presence, and possessing a fine physique, he was universally respected. He was an ardent lover of field sports. The late Mr. Sweeting was never married. He was actively engaged in practice until four weeks of his death, which took place within one day of his attaining his sixty-third year.

PROFESSOR LUIGI LAURENZI.

THIS able surgeon and teacher, the head of the Ospedale della Consolazione in Rome, died on the 5th inst., in circumstances distressingly sudden. He had made his usual morning visit to the wards, and had driven to his house in the Via Borgogna, when his coachman remarked that he alighted with great difficulty, and was deadly pale. The coachman accordingly made a signal to Madame Laurenzi, who happened to be at the window with her daughters, to come down at once. The lady descended forthwith, and with the aid of the coachman, succeeded in assisting her husband in-doors, though he attempted to conceal how ill he was, and deprecated her alarm. Within half an hour thereafter

Digitized by Google

he expired. Professor Laurenzi had, it seems, been suffering from urgent cardiac symptoms for some time, but such was his devotion to his patients and his pupils that, in spite of a very bad night, and contrary to the entreaties of his friends, he insisted on going that morning to the hospital.

His death is widely and deeply lamented. He was in the zenith of his powers, and his high reputation, acquired at the Consolazione by a long series of brilliant operations, had caused him to be respected and consulted as one of the soundest and most successful surgeons of Rome and the province. Some of his lectures and notes of interesting cases, reported in the *Gazzetta Medica di Roma*, had also carried his reputation beyond the Italian frontier. He was, moreover, very popular in the class-room, and a singularly pleasant and affable colleague.

He was buried in the Campo Verano on the morning of the 7th inst., the funeral *cortège* consisting of a numerous train of friends, colleagues, and representatives of the University and learned bodies. In the Piazza di Termini the procession paused for a space, and, according to custom, brief addresses were pronounced in his honour. The speakers were the veteran Dr. Filippo Scalzi and Prof. David Toscani, both of them equal to the melancholy task.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The following qualified candidates, having passed the final examination, have been granted the licence:—

Bridgwood, John Francis, Stafford.
Waite, Davis Allan, London.
Callender, Gerald, St. Mary's Hospital, London.
Wrentmore-Tucker, Robert Frank, Clifton, Bristol.
Farmer, William Henry Francis, London.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on April 7th:—

Shute, George Sidney, Gillingham, Dorset.
Wedgwood, William Brackenbury, Fern Bank, East Dulwich.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Richard Watson Councell, Bristol School of Medicine; Geo. Andrew Gunton, St. George's Hospital.

The results of the Examination in Arts held at the Hall of the Society on March 3rd and 4th last have recently been published. There were 204 candidates, and from the Pass List it appears that 2 were placed in the First Class, 44 in the Second Class, and 116 were certified as having passed in some of the subjects, but not in all. The number of candidates was larger than on any former occasion, though the examination is held four times annually.

A FRESH outbreak of diphtheria is reported from Saltash.

IN the House of Commons on the 12th inst., the Aberdeen Infirmary and Lunatic Asylum Bill was read a second time.

HYDROPHOBIA: M. PASTEUR'S TREATMENT.—Senor Ramon was bitten by a wolf on Feb. 15th. M. Pasteur treated him for hydrophobia, but death has ensued.

PLANS have been selected for the proposed Ashburton and Buckfastleigh Cottage Hospital. The building will, it is estimated, cost £1200.

MIDDLESEX HOSPITAL.—The first Broderip scholarship at this institution has just been awarded to Mr. W. H. Vickery.

THE Duke of Bedford has intimated his intention of contributing £300 to the Endowment Fund of the Tavistock Cottage Hospital and Dispensary, which has recently been started.

REGISTRATION OF PLUMBERS.—Of nineteen journeymen plumbers examined at the last meeting of the examiners, nine candidates passed and ten failed to satisfy the examiners.

THE memorial stone of the new infirmary buildings to be erected for the parish of Birmingham was laid on the 31st ult. The building, which is designed on the pavilion principle, will cost about £70,000.

A GENERAL MEETING of the members of the London cab trade was held on the 8th inst., with a view of increasing the contributions to the Hospital Saturday collection.

THE recent performances at the Theatre Royal, Birmingham, on behalf of the local hospitals, realised £300, which will be distributed amongst the charities on the principle of the Hospital Saturday collection.

FRENCH PROTESTANT HOSPITAL, VICTORIA-PARK.—On Monday last a general court of governors and friends of this charity was held, and a report read which showed that much good work is being done through the agency of the hospital.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the directors of the fund, held on the 12th inst., T. Russel Pickthorn, Esq., Inspector-General, in the chair, the sum of £53 was distributed among the several applicants.

THE usual monthly meeting of the Metropolitan Public Gardens Association was held on the 5th inst., when reports as to the progress of works in different parts of London which have been undertaken by the Association were presented.

THE Committee of the Manchester Southern Hospital are appealing to the public for funds to enable them to establish a lying-in hospital in connexion with that institution, the urgent need for which has been for some time recognised.

ROYALTY AT THE LONDON HOSPITAL.—On the 12th inst., his Royal Highness the King of the Belgians, accompanied by Sir Edmund Currie, paid a visit to the London Hospital. The King inspected many of the wards, and expressed himself highly pleased with the excellent hospital arrangements.

STRAY DOGS IN LONDON.—The number of stray dogs taken by the police during the month of March to the Dogs' Home was 1246. Twelve were killed in the thirty-one days in the London streets as mad or ferocious. Sixty-five persons, including two constables, were bitten during the same period.

THE "JOHN REID" MEDICAL PRIZE.—This prize, of the value of £25, founded by Miss Reid in memory of her brother, the late John Reid, surgeon, Glasgow, and awarded for the best original research bearing on any of the departments of medical science conducted in one of the hospitals or laboratories of Glasgow, has been gained by Mr. R. C. Wakefield for an able paper on "Aneurysm."

THE WOLVERHAMPTON NURSING INSTITUTE.—The Mayor (Mr. T. Vincent Jackson, F.R.C.S.) has received a communication from the Secretary of State, informing him that Her Majesty the Queen has consented to the proposed Nursing Institute, which is to be established in that town as a permanent local Jubilee commemoration, being named "The Queen Victoria Nursing Institute."

MEDICAL MAGISTRATES.—Robert Leamon Bowles, M.D., F.R.C.P., was sworn in on the 6th inst. at Canterbury as a Justice of the Peace for the county.—Robert Spence, M.B., Craigkennochy, Buntisland, has been placed on the Commission of the Peace for Fifeshire.—Dr. Evan Roberts, Penygroes, has been placed on the Commission of the Peace for Carnarvonshire, and qualified at the recent Easter Quarter Session for the county.

STOCKPORT INFIRMARY.—The annual meeting of the trustees of this institution was held on the 30th ult., when it was reported that 1660 out-patients, 825 home patients, 1052 cases of accidents, 621 in-patients, and 650 casualties without recommendation had been treated during the past year, making a total of 4808, against 5006 in 1885. The total amount of income was £3678, against £3492 in the preceding year, and the expenditure amounted to £2931.

ST. THOMAS'S HOSPITAL.—The testimonial to the retiring librarian, Mr. Denison, will be presented in the Library of the Medical School on Monday, May 16th, at 4.30 P.M. Dr. Ord, Dean of the School, will preside. The testimonial will consist of a clock, and a purse accompanied by an engrossed list of the subscribers. In order that the list may be ready, it is necessary that any who have not yet subscribed but intend to do so, should send in their names at once.

Digitized by Google

AN EASTER OFFERING TO THE BROMPTON HOSPITAL. On Sunday last, after a sermon at St. Peter's, Cranley-gardens, by the Rev. F. Byng, the sum of £56 was collected for the benefit of the funds of the above hospital.

THE JUBILEE.—In commemoration of the Jubilee it is proposed to found a convalescent home in connexion with the Adelaide Hospital, Dublin.—On the 6th inst. it was decided by a meeting of the inhabitants of Eastbourne to enlarge the Princess Alice Memorial Hospital.—It is expected that the foundation stone of the Royal Jubilee Children's Hospital, which is to be erected at Gateshead, will be laid early in June.

Births, Marriages, and Deaths.

BIRTHS.

HOLTHOUSE.—On the 10th inst., at Gower-street, the wife of Edwin Hermus Holthouse, F.R.C.S., of a son.

KIRKHAM.—On the 24th ult., at Downham, Norfolk, the wife of F. W. Kirkham, M.A., M.D., of a son.

SANDBERG.—On the 5th inst., at Liverpool Lodge, Brixton-hill, S.W., the wife of Arthur Sandberg, M.D., of a son.

SCOTT.—On the 1st ult., at Batu Gajah, Kinta, Perak, the wife of W. Duncan Scott, M.B., C.M., of a daughter.

STEVENSON.—On the 10th inst., at Camberwell-grove, Denmark-hill, the wife of Leader Stevenson, M.D., of a son.

WATNEY.—On the 8th inst., at Buckhold, Berks, the wife of Herbert Watney, M.D., of a son.

WEST.—On the 7th inst., at King Henry's road, N.W., the wife of J. Arthur West, M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

FULLER—BLACK.—On the 12th inst., at St. Marylebone Church, Henry Roxburgh Fuller, M.D.Cantab., to Julia Louisa, second daughter of the late Patrick Black, M.D.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE PERTH INFIRMARY.

Humanitas writes to us to the following effect:—"The reference to Perth Infirmary in your last issue is calculated to convey a false impression. As a neutral party, but one who for many years has closely watched the course of events leading to this crisis, I can vouch for the fact that, with the exception of Drs. Stirling, Calder, and Graham, the whole of the medical profession in this city and county warmly espoused the cause of Dr. Bramwell. So strong is the feeling against the present infirmary management that a movement is on foot to erect a cottage hospital."

Junior.—1, 2, 3. Occasionally, but not often.—4. The data given are too scanty to warrant a definite conclusion.

Dr. Sheppard (Liverpool).—*Gazzetta degli Ospitali*, Corso Magenta, 48, Milan.

THE SLEEPING MAN.

To the Editors of THE LANCET.

SIRS,—This represents an extreme case of the loss of power resulting from shock, which, according to modern medical phraseology, may be termed "neurasthenia" or "neurosis." It will be interesting to observe to what extent Chauffat will recover his former health. It has too often happened that young women in a similar but not such an extreme condition have been treated with taunts, reproaches, and coercion, under the impression that they were wilful, obstinate, and shamming; in other words, that they were the subjects of hysteria, by which term the condition of neurosis has been erroneously designated. It cannot be too widely known that loss of physical and moral power is the essential characteristic of all such cases, and that the object of treatment should be to restore power and give a helping hand until the patients are able to help themselves. The effect of the maltreatment above mentioned has been to prolong such cases indefinitely, and aggravate them to any amount of intensity; and it must be understood for the future that such prolongation and aggravation are due to mismanagement, either domestic or medical, or both—in other words, that they are factitious.

I am, Sirs, your obedient servant,

Mansfield-street, W., April, 1887. D. DE BERDT HOVELL.

OXALIC ACID AS AN EMMENAGOGUE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 29th last there is a paragraph about the emmenagogue action of oxalic acid. Can any of your readers tell me if it is of any benefit? I should like to try it. Is it a safe medicine?

I am, Sirs, yours truly,

April 11th, 1887. G. W.

Convict.—Application should be made to the Directors or Commissioners of Prisons, and the appointments are in the hands of the chairman, Sir E. Du Cane.

Mr. C. Williams.—We are not aware, but will make inquiry.

FRIENDLY SOCIETIES' MEDICAL ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the letters which have from time to time appeared in your columns on the above subject, and your own remarks upon them. While I entirely sympathise with you and your correspondents in the objects you have both at heart—viz., the maintaining the dignity of the medical profession, and increasing the remuneration of certain branches of it which are at present scandalously underpaid and overworked,—I take leave to doubt whether you are taking the best way to attain them when you attack the Friendly Societies' Medical Associations. I am myself surgeon to such an association. It will, perhaps, surprise some of your correspondents to hear that I find it a very pleasant and comfortable berth. I am not at all overworked, although the association includes between 2000 and 2500 members, the great majority of whom have wives and families whom I am expected to attend on the same terms as themselves. I have found them not merely reasonable in their demands, but almost invariably considerate and thoughtful. There is a managing committee of working men whose treatment of me has from the first been not only fair and just, but even courteous and gentlemanly. Subject only to the condition that my work be done, I am at liberty to arrange it exactly as I please, and I do not feel my present position to be one whit less independent than that of any brother practitioner who has to study the whims and humours of his private patients, while it is a thousand times more so than that of his assistant, with whom I would not change places for treble the salary he pays him. And that brings me, Sir, to the point of my letter, which is this: You will never effect any improvement in either the status or the remuneration of what may be called the lower ranks of the profession by attacking these associations, or trying to dissuade men from entering their service, while you have not a word of censure for the principal who, with an income of, say, £1000 a year, is not ashamed to offer £60, £70, or £80 to a "doubly qualified" man to become his drudge for that wretched pittance. Look at your own advertising columns! I remember well the time when I used to scan them weekly with a sinking, well-nigh hopeless heart. There, Sirs, is your mark; there is the real cancer to be cut out. Till that scandal is reformed you will attack all lesser abuses in vain. Do you seriously suppose that men will be deterred from accepting positions where, if they will only do their work reasonably well and exercise a little tact and common sense, they may easily be comfortable and independent, when in nine cases out of ten the only alternative is an assistancy with its poverty and drudgery? Why, I know a dozen assistants, men of excellent abilities, character, and qualifications, every one of whom is much harder worked and much worse paid than I am. Of course, I would have no objection to be better paid. I think the association get my services very cheap; they are by no means exempt from the common human weakness of being willing to take the maximum of work for the minimum of pay. But associations are not the worst offenders. Leave them alone for a little and turn your attention to the wealthy professional brother who makes a drudge of his assistant and pays him little more than the wages of his coachman. If you can make him ashamed of his meanness, you will earn the thanks of hundreds who need your sympathy and championship far more than does,

Yours truly,

Feb. 15th, 1887. M.O., F.S.M. Assoc.

ANOSMIA.

Senior Surgeon writes that recent letters on this subject which have appeared in our columns suggest to him that the case described may be one of ozæna, with probably diseased bone.

R. B. K.—Our correspondent will not be affected by the new Act.

LONGEVITY.

THE Berlin *Statistischen Korrespondenz*, by way of celebrating the Emperor of Germany's ninetieth birthday, has recently published a list of all the known persons in the Prussian kingdom who are older than the sovereign. At the taking of the census of Dec. 1st, 1885, there was one man of 120 years, another of 118 years; a woman of 117, another of 115; two women of 112; two men and one woman of 111; five women of 110; one man and four women of 109; three men and two women of 108; two men and ten women of 107; thirteen men and seven women of 106; and quite a large number who had attained to their 105th year. The total number of persons who gave their age at over 100 was 160. The Province of Silesia appears to be exceptionally favourable to longevity. Out of the 1073 male persons between their ninetieth and ninety-fifth year in all the Prussian provinces one in five is a Silesian, and out of the 306 men between 95 and 100 years old fifty-one are natives of Silesia. Out of the 2766 Prussian women between the ages of ninety and ninety-five, 371 are Silesians. There are ninety-nine women in Silesia between ninety-five and 100 years old and thirty Silesian women who have exceeded their 100th year. The centenarians are thickest in the district of Oppeln. They are also numerous in the Provinces of Posen and East Prussia; but the western dominions of the King of Prussia, and particularly the Rhineland and the manufacturing districts of Eberfeld, Crefeld, and the Dutch frontier, are not so favourable to extraordinary length of life. At Maidstone a maiden lady named Heathorn, known locally as the "Maid of Kent," has just entered upon her 105th year. She retains her good health and the use of all her faculties. She has a clear and accurate recollection of events which happened before Trafalgar was fought and won, and describes a visit she paid to the *Victory* before and one paid after the battle.

Roma.—The question would, we think, be more appropriately addressed to the editor of the *Queen*.

420.—We quoted the answer as given in the House.

Mr. Simeon Snell.—Soon.

THE INCOME TAX.

To the Editors of THE LANCET.

SIRS,—We are going to ask for a small space in your journal to remind your readers that now is the time for claiming relief and repayment of income tax in all cases where the profits for the past year have not amounted to the sum upon which tax was paid for the year ended April 5th. This claim can be made whether an appeal was made against the assessment or not, and if successful has the additional advantage that it fixes at the same time the assessment for next year necessarily at a lower figure than this year. From the numerous letters we have received in consequence of a letter in your columns mentioning our agency, we are more than ever convinced that medical men are scandalously over-assessed. In all cases where exemption is not claimed by reason of the income being under £150, we advise appeal being made to the Special Commissioners instead of to the District Commissioners. It ensures at the same time greater secrecy and better justice. Should the surveyor attempt to deny this privilege, we hope the fact will be at once reported to us, that we may take steps to have it allowed; we have, in fact, no less an authority than the assistant solicitor to the Inland Revenue to uphold our interpretation of the clause in the Act. As the time for claiming is very limited, notice should at once be given to the surveyor and accounts prepared for supporting the claim. Our special balance sheets have proved a great success, and where adopted last year have been again asked for this year. We require no better testimony to their usefulness.

We are, Sirs, your obedient servants,

THE INCOME TAX REPAYMENT AGENCY.

16, Artesian-road, W., April, 1887.

ERGOTINE IN INTERMITTENT FEVER.

To the Editors of THE LANCET.

SIRS,—In your issue of Feb. 19th, 1887, p. 391, I notice a remark under "Pharmacology and Therapeutics" as to the efficacy of ergotine in intermittent fever. I called attention to this fact in a short paper which I contributed to the *Practitioner* in the latter part, I think, of 1879. The main object of the paper was to point out the great value of arsenic in cases of metrorrhagia. The last paragraph of my paper runs as follows:—"The fact of the efficacy of quinine in ague, taken in conjunction with its action on the uterus led me to try ergot in cases of ague, and I found it extremely efficacious in checking the paroxysm." Since that time it has been my constant practice to use ergot in the milder cases of intermittent fevers with good effect.—I am, Sirs, yours faithfully,

Meean Meer, March 20th, 1887. C. S. RANKING, M.D.

THE BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Would you kindly allow me to acknowledge the following subscriptions received up to the present date in aid of the above fund? Lennox Browne, Esq., £1 1s.; Dr. Robert Barnes, £1; Dr. Holman (Reigate), £1 1s.; M. G. Biggs, Esq., 10s. 6d.; J. T. Boyd, Esq., 10s. 6d.

I am, Sirs, yours faithfully,

Meadow Side, 23, Upper Richmond-rd., Putney, April 13th, 1887. G. STANLEY MURRAY, M.D.

WIESEN AS A HEALTH RESORT FOR PHTHISIS.

To the Editors of THE LANCET.

SIRS,—I should be glad if you could find space for a few remarks relating to Wiesen in connexion with the article in THE LANCET of March 19th on "The High Altitude Treatment of Phthisis." Your correspondent in this article says: "We are still without definite statistical information on the results of treatment at Wiesen last winter." The time during which I have practised here has been too short for me to be able to furnish the statistics which your correspondent wishes for, nor have I as yet sufficient material to publish, though I hope before long to be able to give more exact information. But I may say that we have reason to be satisfied with the success already attained. Of thirty cases which have been under my observation this winter, the majority (about two-thirds of the cases) have made considerable progress, and even severe cases have done very well. When we ask whence this success arises, we can only attribute it to the peculiarly favourable and isolated position of the place, far from all disturbing sounds. It also enjoys, in addition to its pure air, the advantage of being a small health resort, where every step of the patient can be regulated and controlled by his doctor. There are here no opportunities for pursuing any pleasures which might be prejudicial, since there is nothing besides the two excellently arranged hotels from which the visitor can derive amusement. Certainly for those who have no great admiration for the beauties of nature and but few resources in themselves the place may appear somewhat dull. But he who realises how dependent recovery is on a well-ordered life, and how important it is to be healthy, will surely renounce willingly the pleasures of life for a short season in the interest of his health. I am, Sirs, your obedient servant,

Wiesen, April 7th, 1887. P. BALZER, M.D.

Mr. E. D. McNicoll.—The matter is rather one for the advice of a solicitor. We should deprecate the publication of the correspondence in a local paper.

Mr. Harrold Fenn is thanked.

SHAM PATIENTS IN KENSINGTON.

To the Editors of THE LANCET.

SIRS,—The same thief who paid Dr. Longhurst a visit called at my house, evidently in pursuit of plunder. Having watched me out of the house, he rang the bell, and was allowed to remain in my consulting-room about two minutes. My wife, fortunately being in, asked what he wanted. He said it was a professional call, and that he would call at 3 o'clock in the afternoon. I need hardly say he did not return. He gave the name of "Kerr," and went on to the house of my friend, Dr. Lew, where he gained his object, pocketing a case of surgical instruments and a silver cigarette case. Such scamps ought to be "run in" at once, and have at least five years' penal punishment.

I am, Sirs, yours truly,

Earl's Court-road, W., April 12th, 1887. WOOD HILL.

Atropos.—We should not advise vaccination round a nævus in the situation described.

Clinical Lecture
ON
TROPICAL ABSCESS OF THE LIVER.

By SIR DYCE DUCKWORTH, M.D., F.R.C.P.,
PHYSICIAN TO, AND LECTURER ON CLINICAL MEDICINE AT, ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—The subject of hepatic abscess is one of great interest to all English students of medicine. It cannot fail that some of you will have to practise your profession in some part of our tropical possessions, and in these days, when locomotion is so rapid and easy, some of you will also as certainly not fail to have experience of this disease at home. I think it is not unlikely that abscess of the liver is now less often met with in the tropics than formerly. I have no facts to support this view, but I conceive it to be likely, because Europeans nowadays take better care of their health, eat and drink less than formerly, come home at shorter intervals to recruit their powers, and are thus less exposed to and saturated with malarial influence.[1] For twenty-one years I have had a special experience of Anglo-Indians of all ranks in connexion with the services of several of the great Indian railway companies, and I may at once state that my experience of hepatic abscess as a cause of invaliding in these persons has not been extraordinary. To be sure, the worst cases have died in India or on their way home; others have had favourable, and generally rapidly favourable, terminations by rupture of the abscess, usually into some part of the gastro-intestinal tract. Others again, such as the case I take for the subject of to-day's lecture, have developed the symptoms of their malady after arrival in this country. I wish first to point out to you that all Europeans in the tropics are not equally liable to hepatitis and abscess, as I have here and elsewhere declared; the special predispositions of persons materially affect their tendency to go wrong in any morbid direction. A large chapter in the history of medicine within the tropics has yet to be written, which shall relate to the influences of climate, and the habits thereby engendered, upon individuals of the several constitutional conformations or so-called diatheses. To such a chapter the late Dr. Norman Chevers contributed very notably and with great ability. He formed the opinion that persons with tubercular proclivity were more than others apt to suffer in India from dysentery, while strumous persons were similarly predisposed to hepatic abscess. In respect of idiopathic hepatic abscess, he did not consider that any of the ordinarily assigned causes, such as malaria, intemperance, dysentery, portal pyæmia, and tuberculosis, were essential, and he concluded that the influence of tropical heat was specially causative.[2]

You have been already taught in your systematic lectures that hepatic abscesses are mainly divided into two classes: first, the pyæmic or multiple form, and, secondly, the tropical or solitary form. This is an artificial division, and worthy of retention; however, you must expect to find in practice that there may be more than one abscess owning no direct connexion with either dysenteric ulceration or pyæmia. The etiology of liver abscess has been a hotly debated question, especially in respect of the relation which dysentery bears towards it. At one time the abscess was thought to induce the dysentery; later it was thought that dysentery led to the abscess. Again, it was believed that both were due to a common cause. The late Dr. George Budd, of King's College and the *Dreadnought* Hospitals, was one of the earliest advocates of the direct connexion between dysentery and hepatic abscess, teaching that the latter was due to direct absorption from the ulcerations in the colon of purulent or infecting matters. This theory, you see, is especially an embolic or pyæmic one. Hepatic abscess, as most commonly seen in Europe, is of the pyæmic or multiple variety, and is naturally regarded as a most fatal malady. No one now doubts the connexion I have just described, cases being frequent in which purulent absorption takes place from breaches of surface in any part of the alimentary canal drained by branches of the portal vein. Thus gastric ulcer and ulceration of the gall-bladder and bile-ducts, and operations on the rectum, may induce embolic abscess in the liver. A noteworthy point in the matter is this, that dysentery is far more common *uncomplicated* with hepatic abscess. There must, therefore, be some other factor than mere ulceration to account for infecting absorption and resulting hepatic abscess, and this factor is without doubt *a special infectivity attaching to the detritus of the bowel ulcerations*. It is very noteworthy that no such accident occurs in connexion with the ulceration of enteric fever or tuberculosis. With suppurative pylephlebitis we are not now concerned; the mischief here extends along the veins involved. Next, observe that hepatic abscess in the tropics is common enough when no history of dysentery is to be had in the case, no pyæmia is present, and no very obvious cause can be adduced. The pyæmic theory fails to fit such cases; and in the majority of instances in the tropics the abscesses are either solitary or limited to two or three, whereas in Europe we commonly find innumerable points of suppuration in the liver, and readily discover their origin in some distempered breach of surface in the line of the portal circulation, or in some other part of the body. Hence, both forms of abscess may occur in the tropics, but the pyæmic or multiple form only arises in Europe. A large solitary abscess may occur in connexion with dysentery in the tropics, or several small dysenteric abscesses may coalesce gradually into a large one; but this is not often seen in this country. Multiple pyæmic abscesses are the rule here. The late Dr. Moxon thought the differences between tropical and pyæmic abscesses depended on their different ages or duration, and that ulcerations or cicatrices of them would be usually found if carefully sought for. But this view will certainly not apply to the history of many cases. The embolic theory has captivated the attention of pathologists to the exclusion of that which explains the production of abscess as the outcome of a specific hepatitis. The latter explanation appeals rather to the bedside than the deadhouse physician. Many differences of opinion in medicine are, in my thinking, to be thus explained. Clinical explanations may be seemingly fanciful sometimes, but they cannot be dispensed with till post-mortem research has modified or confuted them. It would appear that with improved methods of treating tropical abscess the opportunities for examining the intestines for cicatrices of ulcers will grow fewer and fewer.

What, then, are the probable causes of the solitary or tropical abscess? Without doubt they depend on peculiarities of life and climate. It is certain that tropical climates induce in many Europeans congestion and enlargement of the liver. Unusually, hot weather in Europe produces this much, unless great care in diet and habits of life be practised. Indulgence on the part of tropical residents in European habits as to eating and drinking, with undue exposure to the sun, are to blame to a large extent for this. But beyond these causes, there is something specific in the effects of prolonged heat upon the functions of the liver; all constitutions not being equally susceptible, however. Again, it seems certain that malarial poisoning has largely to do with this congestion. The spleen suffers with the liver under this exposure, and both organs fail of their due functions. It is noteworthy that hepatic abscess is less common by far in the West than in the East Indies and China. Malaria is perhaps equally pernicious in both. It is not remarkable that the bowels should suffer sometimes together with the other viscera mentioned, and hence, with exposure to chill, the risks of impure water and of improper food, all the conditions for the onset of dysentery are provided. In Indian nosologies you will often meet with the term "hepatitis": acute and chronic varieties are mentioned. No very clear distinction has been drawn between congestion and hepatitis. If the inflammatory process reaches a certain point, we naturally have to deal with abscess as the outcome of it. Chronic hepatitis is applied to a long-standing condition of hyperæmia and engorgement, which, if neglected, usually passes into a form of cirrhosis. As indicating in some measure the etiology of the troubles we are now considering, note that women are more rarely the subject of such hepatitis in India as leads to abscess, and that in children the disease is practically unknown, although

[1] Sir Joseph Fayrer, however, informs me that he thinks hepatic abscess is now as common as formerly.
[2] Sir Joseph Fayrer and others with large Indian experience do not, however, agree to this.

Digitized by Google

dysentery is very common amongst them. Hepatic abscess is rare under the age of twenty, and more frequent after twenty-five years. These facts, which I give you on the authority of able observers—Dr. John Macpherson and Sir Joseph Fayrer—would indicate that alcoholic intemperance, with greater exposure to solar influence and intenser grades of malaria, are not a little causative, and this is the opinion I have been led to form.

With these remarks, with which I have thought it well to begin my lecture to-day, I now pass to the case illustrating it. It is that of M. N——, aged twenty-eight, single, a medical officer practising in the Bombay presidency. He went out to India in 1883. He is of excellent constitution, and his family history is satisfactory. He has been stationed in several districts, and been exposed to malaria. After being out for a few months he had a slight attack of dysentery, being laid up for ten days. He made a good recovery, and had no return of this trouble. He was always temperate. Within the first year of his sojourn he had an attack of catarrhal jaundice, and he also suffered six or seven times, but not severely, from malarial fever. As he expressed it, "he knew he had a liver." In June, 1886, he left India on leave of absence for three months and came home, landing on July 19th. He believed himself to be in perfect health. In August he suffered from chill after being overheated, and was seen by Mr. Coalbank of Twickenham, who found him confined to bed, suffering much pain from pleurisy in the left side (postero-lateral region). His liver was then enlarged and tender. His temperature reached 103° and 105°. (Dr. Norman Moore saw him later in my absence, and confirmed Mr. Coalbank's opinion as to pleurisy, with malarial fever.) He lost flesh somewhat rapidly, and looked ill. On Sept. 16th he was recovering, but was still weak, had a coated tongue, and wavy, uneven pulse. Dr. Sedgwick Saunders, who saw him at that time, refused to allow him to return to India. On Oct. 28th I saw him for the first time. He was still thin and cachectic-looking. I could find no physical signs anywhere in the chest beyond a trifling amount of dulness, with imperfect respiratory note, in the left postero-lateral region. There was no jaundice, and the urine was natural. I sanctioned his return to India in November. On the night of Nov. 1st, after a busy day in London, he awoke with very severe pain at the epigastrium radiating to the left side. The pain was of a stitchy, "catching" character, and there was agonising cough. In no way could he account for this attack. He had had a slight cough for a few days previously. He came up from Twickenham and saw his friend, Dr. Goodhart, who examined him, but found no signs of pleurisy, but observed some fulness about the left hypochondrium. His temperature was raised to 102° and 103° at this time. Cough troublesome, with glairy, tenacious sputa, not rusty. He kept to bed for three weeks. The pain was very severe, and nothing relieved it. There was a dull dragging pain in the left costal arch, and much epigastric tenderness. No rigors. His weight was then 10st. 7½lb., his usual weight being about 12st. On Nov. 30th I found the same physical signs as before in the left pleura. On Dec. 11th I saw him again. Dr. Andrew had also examined him, and found nothing to explain his severe pain, which was attributed to pleural adhesions. The pulse was 84, and regular. He was still looking pale and ill. I had a suspicion of hepatic mischief as the cause of all his trouble, but there were no physical signs to justify any certainty of this at this time. I recommended an extension of leave for three months, careful regimen, and good diet. On January 19th, 1887, Dr. Andrew again examined him, and found a tumour projecting under the left costal arch, indistinctly fluctuant. No improvement had occurred in the general health. There was a slight icteric tint of the conjunctivæ. On the 21st Dr. Andrew and I saw him together. There had been no rigors, no sweatings, no shoulder pain. The tumour was evidently an abscess in the left lobe of the liver. Slight pulsation was communicated to it from the heart. At the beginning of January severe pain had returned about the ensiform cartilage, but there had never been freedom from pain in the left side since October. Vomiting had occurred about once daily, generally about an hour after taking food. There was much flatulence. He was admitted to John ward on Jan. 22nd. The temperature was 98·2° on the first night. The tongue was coated all over. Bowels open; stools bilious. Urine: Specific gravity 1025; faintly alkaline; depositing phosphates; void of albumen, blood, glucose, and bile. Heart's apex in fifth space, in normal situation. Sounds natural. Pulse 72, of fair volume and power, and regular. In the chest nothing abnormal. The liver dulness began at the sixth rib. To the left of the epigastrium a rounded projecting tumour, everting the cartilages; deep-seated fluctuation made out; the skin was not red over it. Spleen not felt. Abdomen otherwise natural. Lower edge of right lobe of liver not felt or apparently depressed. On Jan. 23rd the temperature reached the highest point recorded in the hospital—100·2°. On the 24th, after a restless night, the temperature was 99·2°. Chloroform having been administered, Mr. Langton aspirated the tumour, and twelve ounces of chocolate-like grumous matter was withdrawn, containing pus and débris of blood. Temperature last night 98°; to-day 97·8°. Sick after chloroform. Dragging pain relieved, but pricking pain in region of abscess. Pulse 64, of good volume and strength. Had better night. On the 26th the temperature was 96·4°; pulse 72, feebler and irregular. Much nausea, and vomited once. Urine loaded with urates. On the 29th he was going on very badly; no action of the bowels. It was decided now to have the abscess freely opened. Under chloroform and with full antiseptic precautions, my colleague, Mr. Langton, cut down through the left rectus abdominis and came upon thickened adhesions between the sheath of muscle and peritoneum. He passed in an exploratory syringe, then a director, and then his finger. Reddish pus (six ounces) flowed freely away, and an indiarubber tube was inserted and stitched into the lips of the wound. Iodoform and antiseptic dressings were used. The nausea continued for two days and gradually passed off. Nourishment was badly taken, and a quinine and nitro-hydrochloric acid mixture could not be borne. Nutrient enemata were given in default of sufficient by the mouth, and about two ounces of brandy were given each day. The wound did well and discharged freely. It was dressed daily antiseptically, and remained quite sweet. The temperature remained subnormal. The appetite soon became large, and flesh was rapidly gained. On Feb. 12th the patient was sitting up daily and making progress in all respects.

Let me briefly review the history and course of this case, and comment on the procedures of treatment. The patient while in India suffered from most of the ailments that befall Europeans, and, though never severely ill, it is clear that the climate and the circumstances of his life told upon him. Thus he had dysentery, malarial fever, and catarrhal jaundice. I have already told you that he was a very temperate man, and lived carefully. In June of last year he left India, feeling in perfect health, intending to stay a few weeks only at home. In August he began to suffer after a chill, and had pleurisy and remittent fever. At this time the pleurisy was at the back of the chest, on the left side. He failed to make a satisfactory recovery of his general health, losing flesh, looking ill, and having a not very explicable cough. It would be interesting to know the temperatures that occurred at that period. Very early in November a second attack of pleurisy unaccountably came on, this time near the cartilages adjacent to the ensiform cartilage, the pain being very severe and the temperature raised. No rigors and no sweatings. Six weeks later, although the second attack of pleurisy had passed off, there was no improvement in the general health, and a pinched and sallow appearance was manifest. Physical signs alone were insufficient to explain this condition. In three weeks' time there was a return of the severe pain near the ensiform cartilage, and in less than three weeks afterwards a tumour was detected in the left lobe of the liver. Gentlemen, it is easy to be wise after an event, but the fact remains that while the symptoms I have detailed to you fall in admirably with those that might be expected in such a case, there was a marked absence of physical signs to justify a confident diagnosis of all that was proceeding in the liver. Suspicion there was in the minds of several of those who saw the case, but nothing definite could be established, and certainly nothing could justifiably have been done more than was done.

The case, then, illustrates a point which has long been recognised in respect of the latency and insidious character of hepatic abscess. Large collections of matter may occur in the liver without any symptoms distinctly referable to that organ. In this instance it is not clear when the abscess began to form. It is quite possible that the disease was already in progress before the patient left India. The pleuritic attacks were plainly significant of the mischief that was going on below the diaphragm, and the severe pains near the ensiform cartilage betokened adhesive capsular

Digitized by Google

hepatitis of the left liver lobe, the results of which ultimately proved so protective and beneficial. You will understand that according to the special seat of the abscess so will the symptoms vary in any case. Thus, if they come to press or point upwards, pain will be felt and irritation be excited in the diaphragm, pleura, or lung, with cough; if downwards, there will be interference with the functions of the stomach, and nausea and vomiting may be expected. In this instance irritation occurred on both aspects of the left lobe, the pleura and stomach both being implicated. The liver substance appears to be little sensitive, but when the capsule is involved there is commonly severe pain; hence the pain in hepatic abscess is probably due to pressure on the capsule and to the happily protective perihepatitis that is often set up as the abscess pushes its way.

The leading symptoms, when present, of abscess of the liver are fever, hepatic pain, severe gastric catarrh, with foul coated tongue, nausea, vomiting, hiccough, and inability to lie on the left side. The abdominal wall is rigid, one or other rectus muscle contracting to protect tender parts below. Pain in one or other shoulder or scapular region is sometimes met with, induced either through the reflex mechanism of the phrenic and cervical nerves, or through the pneumogastric and spinal accessory branches. There is great languor and lassitude, rigors are common, and nightly rises of temperature. Slight jaundice is present, simulating ague. The urine is loaded with lithates, and may contain albumen. As suppuration proceeds profuse sweats occur. Bile is present in the stools. Tropical abscesses point usually superficially, and present in a low intercostal space or under the cartilages in the hypochondria. The spleen is not enlarged as a rule. Now in this case there were no rigors, no shoulder pains, and no sweatings. The absence of these symptoms added somewhat to the difficulties of diagnosis.

Respecting the treatment. There is now only one opinion as to the necessity of early and free opening for tropical hepatic abscess. At one time, in India, it was thought best not to operate, and to wait for spontaneous bursting. Nature was found to be sometimes kind, and to allow the pus collection to empty itself into some evacuant channel. But, unhappily, rupture into the lung or pericardium, or into the peritoneum, is greatly to be feared. Amongst the triumphs of modern antiseptic surgery is the treatment of hepatic abscess. A more important question remains for consideration in each case, and it relates to the establishment of adhesions between the liver capsule and the parietal peritoneum. There is always an apprehension of the abscess-cavity collapsing after being opened and discharging into the peritoneum. To prevent this accident, preliminary measures have been recommended to set up inflammatory adhesions. This question also comes to be discussed in operating on hydatid cysts in the liver. It has been proposed to set an issue with caustic potass and peas, and thus secured the end desired. I have seen this method practised twice, but do not expect to see it again. Simply tapping by aspiration is often performed in the hope of setting up adhesions in advance of the subsequent graver operation. This was done in the present case partly for completing the diagnosis, and with the prospect of aiding adhesions. Again, it is proposed to cut down to the surface of the tumour and stitch the edges of the wound to it, completing the operation a few days later. In by far the majority of cases these methods are unnecessary. In the progress of the abscess, as it pushes towards the capsule, perihepatitis is often induced and firm adhesions are set up. This is not, perhaps, so often the case in suppurating hydatid cysts. In support of the general safety of immediate and bold operative measures, we have the unique experience of Sir Joseph Fayrer and of many of our surgical brethren in India, a body of men of whom this country is not, I think, sufficiently appreciative, who now never hesitate to evacuate these abscesses so soon as they diagnosticate them, and practically disregard the question of adhesions. Their results were so satisfactory that we may fairly follow them in this practice. Any remaining considerations, such as insertion of drainage-tubes, relate so specially to surgical details that I cannot enter upon them. If decided improvement does not follow the evacuation of the abscess, we may suspect either imperfect drainage of it or the existence of an independent one. You remember that there may be two or three centres of suppuration in even tropical non-embolic cases. I would add a few words on the subject of washing out the abscess cavity. I believe this to be unnecessary if free drainage is secured, and even if done antiseptically to be a possible source of mischief. In this case, as in cases of empyema, I believe it to be the better practice to abstain from washing out the cavities. You may ask if any surgical interference is ever called for in respect of dysenteric or multiple abscesses. Even in these cases, according to Sir Joseph Fayrer, puncture and evacuation may be useful.

Respecting the prognosis for the future in any case where the abscess has burst favourably or been opened successfully, we have no grounds for believing that any special immunity from a future attack exists. Such patients do best to leave the tropics and live at home, but not seldom they return and do well. Second attacks may occur, but it is generally believed that these may be due rather to undeveloped or residual abscesses, which have later become active. A residual abscess may long remain encysted, and be symptomless, till by gradual thinning of its walls it suddenly gives rise to fatal symptoms. Dr. Maclean and Professor Aitken have related such a case to me from their experience. Hence, there must always be a somewhat guarded prognosis in any case, and for some long period. In my experience, where abscesses have burst favourably the patients seldom long remain unmindful of their trouble. Dragging pains, probably caused by adhesions, are sometimes suffered from. In the case of an officer of Horse Artillery under my care, he could never wear his sword comfortably through a field day. With care in diet, and in all other respects, some of these patients manage to complete their tropical career fairly well. The drugs which prove useful are quinine, cinchona, and mineral acids. When the tongue is coated and there is no appetite, alkalies, such as sodium bicarbonate with bark, given after effervescence with a little citric acid, do better than quinine and acid. Subsequently, the chloride of ammonium, with some bitter, or with the mineral acids, is very useful. Prolonged stay at the seaside in some mild or sheltered part is the most efficient climatic agent. Sea-bathing and cold baths must be forbidden, and warm sea-water baths or tepid sponging only be sanctioned.

I will draw out for you on the board the leading characters of the two varieties of hepatic abscess, so as to impress them on your memory. Remember, however, that all such categories are made on somewhat rigid lines, and that large bedside experience tends to impair one's estimate both of tabulation and statistics:—

HEPATIC ABSCESS (two chief varieties).

A. *Tropical* (specific suppurative hepatitis).—Solitary, or few in number. May be very large, form rapidly, or occupy some months before urgent symptoms arise. Course often latent and insidious. Connexion with dysentery not commonly traceable. Infrequent in women; unknown in children. Rare before twenty; commoner after twenty-five. May occur in temperate and careful-living persons. Tendency to burst; jaundice slight; spleen not enlarged. Probably due to solar, climatic, and dietetic influences. Some constitutions—e.g., strumous—more apt than others to suffer. Commoner in East than in West Indies, and occurs on Mediterranean littoral.

B. *Pyæmic* or *Embolic* ("dysenteric abscess").—Multiple, may be very numerous and small. Course rapid. Follows on dysentery or septic inflammation of parts drained by portal vein. Part of general pyæmia, especially after head-injuries and damage to medulla of bone. Jaundice marked; Spleen enlarged. Seldom bursts. Occurs independently of climate, but much connected with dysentery.

THE TOWER HAMLETS DISPENSARY.—This old institution, founded in the year 1792, seems to be well supported. In spite of the hard times, donations and new subscriptions have been received which have reduced the indebtedness of the dispensary. The mortality in the year, with a total of 4497 cases, was 75. The chief causes of death were: bronchitis, 11; consumption, 10; whooping-cough, 5; pneumonia, 4. The payments on account of the dispensary are £511 14*s.* 10*d.*, of which the patients contribute £139 4*s.* All the patients do not pay. They are divided into two classes—those receiving relief gratis, and those coming under a system of payments, as follows: recipients to pay an entrance fee, and on each renewal of the letter, 6*d.*; on each subsequent attendance at the dispensary, 3*d.*; for each visit at home, 6*d.*; teeth extracted, 3*d.*; midwifery fee (by midwives), 3*s.* 6*d.* Would it not be possible to make all such institutions provident—i.e., to procure systematic periodical payments throughout the year, and pay the medical men an honorarium at least?

ABSTRACT OF

Lumleian Lectures

ON THE PATHOLOGY OF INTRA-UTERINE DEATH.

Delivered at the Royal College of Physicians of London, March, 1887,

BY W. O. PRIESTLEY, M.D., F.R.C.P., LL.D.,
CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL, AND LATE PROFESSOR OF OBSTETRIC MEDICINE, KING'S COLLEGE.

LECTURE II.

IN this lecture Dr. Priestley spoke of the causes of intra-uterine death which are associated with faulty conditions of the fœtal envelopes and fœtal appendages, taking first those which properly belong to the earlier part of pregnancy. He stated that a too scanty formation of the decidua may lead to the growth of a placenta too small for the needs of the embryo. Charpentier believes that an arrest of development in the decidua reflexa, or its premature destruction, are frequent causes of death in the embryo. When the ovule has been successfully implanted in the decidua, and the normal development of the decidua reflexa and other structures is going on in progressive series, there is great tendency in some women to go wrong, apparently from mere weakness of the outer structures which form the ovum. In some women the union between the pregnant uterus and the decidua is so unstable that a fall or stumble, or a shaking of any kind, may be quite sufficient to detach a portion of the latter, rupture the intervening vessels, and cause extravasation of blood. If limited, these extravasations need not interrupt the continuance of pregnancy. If more extensive and separating a larger portion of the decidua, they necessarily interfere with the nutrition of the ovum, produce death of the embryo, and precipitate abortion. The same result may ensue from contractions of the uterus, either provoked by local irritation directly applied, or from reflex causes—as, for example, suckling a child after a fresh pregnancy has commenced. Occasionally, during the very early stages of gestation, blood flows directly into the decidual cavity, and fills it with coagula. The result is either that all traces of the embryo and its immediate surrounding structures are obliterated, or the embryo is compressed and destroyed by the invading flood, rudimentary portions of it only being discovered. In from the second to the third month the decidua reflexa or ovuli is fully formed, and the villi of the chorion are everywhere embedded in its substance. Then another form of hæmorrhage may occur. In this the blood is not alone extravasated between the decidua vera and the uterine wall, or into the meshes of the decidua itself, but between the decidua reflexa and serotina, and the chorion or outermost of the true fœtal membranes. In the process of development the villi of the chorion are pushed into the decidual tissue, and are soon surrounded by the bloodvessels which are to form the maternal placenta. The decidua is, then, a highly vascular membrane, especially at the site of the future placenta, and the maternal vessels which everywhere ramify through it undergo a development which in the human body is unique. Appearing first as capillaries, they rapidly enlarge, and eventually become sinuses, which are filled with maternal blood, and in which the fœtal villi are eventually suspended. These delicate and rapidly dilating maternal vessels are very liable to rupture. Hæmorrhage taking place in this locality floods the loose tissue of which the decidua serotina and reflexa is composed, and destroys or compresses the chorion villi implanted there, being sometimes so extensive as entirely to surround the embryo. The nutrition of the embryo is arrested if the extravasation be extensive enough to interrupt the normal circulation through the imperfectly formed placenta, and the embryo may be found stunted and shrivelled, suspended by its umbilical cord from some part of the amniotic cavity. These extravasations of blood between the chorion and the decidua constitute the typical "apoplexy of the ovum" described by many authors. It is found in a multiplicity of forms and modifications, and is no doubt produced by a variety of causes. Thus it may be produced by faults in early development, or by any cause which produces detachment of the well-formed decidua from the uterine walls, or from rupture of its bloodvessels. Apoplexy of the ovum is a very common cause of embryonic death, and, judging from the large number of specimens preserved in the various museums, is by far the most frequent of all the pathological changes affecting the early ovum. Congestion of the decidua is, it is believed, a sufficient and adequate cause, irrespective of any other, to produce rupture of its bloodvessels and extravasation into its substance. Inflammation of the decidua, taking various forms, has been described by Virchow, Hegar, Schroeder, and Spiegelberg. Slavjanski has described an acute form associated with cholera in pregnant women, and leading to hæmorrhage with the death of the fœtus. These inflammations are, however, generally chronic, and are continuations or extensions of previously existing inflammation in the unimpregnated mucous membrane of the uterus, and three forms have been described as producing different alterations in the decidua.

I. The first, "chronic diffuse endometritis" of authors, produces a thickening or hyperplasia of the uterine mucous membrane, which when conception occurs renders it unfit for the reception and growth of the fecundated germ. According to Spiegelberg the hypertrophy consists in a development of connective tissue, which not only thickens but indurates the membrane, and extends down to the muscular fibres themselves. The arrangement of the hypertrophied tissues is such as often to give rise to the appearance of cysts, which, however, are probably only the "cups" of Montgomery enlarged. Schroeder regards it as a chronic and diffuse proliferation of the mucous cells, both parietal and reflected. The thickened membrane presents, he says, the large cells of the decidua, united *en masse*. By their proliferation, particularly in the deeper layers, they may produce a cavernous structure, and even form cysts. This alteration, he says, produces death of the embryo and abortion, by the irritation which the inflammation produces on the uterine nerves. A variety of this chronic diffuse endometritis constitutes the "adhesive endometritis" of Braun. It takes place in the later months, and it then attacks the utero-placental mucous membrane, setting up such irritation that it imperils the life of the fœtus and precipitates premature labour. Strictly speaking, the affection may be regarded as a disease affecting the placenta. One of its results is to produce adhesions between the placenta and uterus, and so complicate delivery. Its presence is characterised by the fœtal movements giving pain, and often, besides this, acute pain and tenderness are experienced in the walls of the womb, which some have described as "uterine rheumatism." It may be produced by chills, overwork, &c.; and, according to Kaschewarowa, it is one of the results of syphilis, or a pre-existing endometritis.

II. A second form of inflammation affecting the decidua has been described by Virchow under the name of "polypoid endometritis." It would seem to be only a more advanced degree of the inflammatory condition just described, but the mucous membrane is thickened to twice or thrice its ordinary depth, and prominences and projections like polypi protrude from the free internal surface.

III. A form of inflammation affecting the decidua has been named "catarrhal endometritis." It is characterised by a persistent discharge from the gravid uterus, which constitutes the "hydrorrhœa" of pregnant women. A woman, generally about the sixth month of pregnancy, loses suddenly and at intervals a quantity of transparent colourless fluid, analogous to ascitic fluid. This is succeeded by a dribbling more or less prolonged and without pain. The pregnancy may go on to term; and the membranes, as a rule, are found intact.

Discussing morbid changes in the chorion, Dr. Priestley remarked that the pathological change which has received the most attention is what is commonly called cystic, or vesicular, or hydatid degeneration. The literature on this subject is abundant, and was reviewed at length. As to the manner of the formation of the cysts, most authors agree in regarding them as the results of pathological changes of one kind or other in the villi of the chorion, but the crucial question, and one which has been much discussed, is whether the disease precedes the death of the embryo and so causes its death, or whether the embryo dies first and the disease is the consequence. On this point authors differ. Dr. Priestley gives his adhesion to the former theory. Alluding to the amnion, Dr. Priestley pointed out that it does not

Digitized by Google

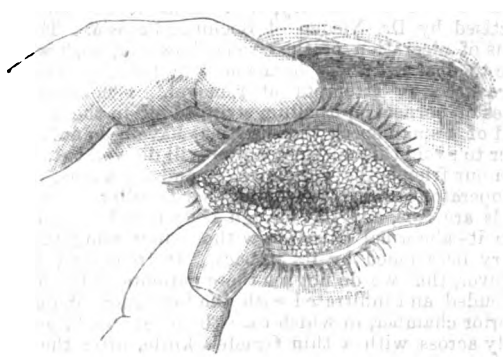
always escape the effects of extravasation, beginning in the decidual structures. The condition which has received most attention in connexion with the pathology of the amnion is hydramnios, or superabundance of liquor amnii. The result to the mother is that she may suffer greatly from the distension. Respiration is impeded, and the patient may not be able to lie down night or day. The digestion is deranged from physical pressure, and the heart's action is disordered, while other secondary symptoms, such as œdema of the lower limbs and blueness of the countenance, may be superadded. The effect on the child is to impede its development, and, if born alive, it is commonly too feeble to survive its birth. Frequently the child is affected with dropsy, hydrocephalus, or other complication. Two or three facts have been distinctly made out in relation to its pathology. 1. Scarpa noticed a coincidence between this form of dropsy and the presence of twins. This has been fully confirmed by the observations of Winckel, McClintock, and others. 2. In pregnancies complicated with hydramnios, the child often presents some vice of conformation. Monsters are, in fact, common with this affection. 3. The children born with a superabundance of liquor amnii often present evidences of syphilis, and this whether they are born dead or alive. 4. Hydramnios is comparatively rare in first pregnancies as compared with others. 5. It is more frequent with female children than males. Of thirty-three cases collected by McClintock only eight were males.

The impression derived from a careful study of all the circumstances is, that hydramnios is not a product of inflammation of the amnion, as some have supposed, but that it arises sometimes from constitutional conditions affecting the mother, sometimes from local causes.

Clinical Lectures ON DISEASES OF THE EYE.

Delivered at the Nottingham and Midland Eye Infirmary, December 9th, 1886,

BY C. BELL TAYLOR, M.D., F.R.C.S.,
SURGEON TO THE INFIRMARY.



LECTURE V.

(Concluded from page 767.)

HITHERTO, gentlemen, I have been speaking exclusively of bacterial purulent ophthalmia—a disease which, so far as the infant and infection from the maternal passages are concerned, must occur within the fifth day of birth or not at all; and it is well that you should note this, because, of course, a baby may get a cold in its eye any time, just the same as you or I. Such accidents are, however, for the most part trivial, infrequent, and readily dealt with by the simplest remedies. It is different, however, when catarrhal ophthalmia attacks older children or adults living in common, in barracks, schools, reformatories, poor-houses, prisons, asylums, refuges, penitentiaries, and the like, where the inmates are often overcrowded and placed under defective hygienic conditions; for the disease, which is highly contagious—nay, more, under certain circumstances infectious,—spreads rapidly, is apt to assume what is termed the follicular form, to develop minute bodies beneath the conjunctival epithelium resembling sago grains,[1] and to culminate in that horrible, chronic, and intractable disease which we know as trachoma (τραχός, rough), or granular lids. These defective hygienic conditions, combined with filth, misery, and overcrowding, exist to a high degree in Egypt, the cradle of the arts and sciences, and, as Haller has remarked, "cæcorum in omni tempore fœcunda nutrix," where the cold nights, the heavy dews, the hot days, the glare, the flies, the atmosphere of dust, and periodic inundations, have rendered the disease endemic to such an extent that at one time there were as many as 8000 blind persons in the mosque at Cairo; and Volney, in his interesting "Voyage en Syrie," tells us that of 100 persons he met accidentally 50 were affected, 20 quite blind, 20 with films and discharges, and 10 with only one eye apiece. As might have been anticipated, the soldiers of Sir Ralph Abercrombie and Napoleon I., at the close of the last century, imported the disease into Europe, where it raged at one time to such an extent that 4000 British soldiers were blinded by it, 5000 French were in a similar plight, and 10,000 others had lost one eye apiece. In this disease the inside of the lid resembles a nutmeg-grater, a sliced fig, or a granulating wound (Fig. 2); and by constantly rubbing upon the cornea creates so much irritation, inflammation, vascularisation, and formation of protective tissue, that the patient is pretty nearly blind; and in some cases the cornea is so completely covered with a fleshy mass (*pannus*) that it is not possible to see the eye at all.

Here is a patient on whom I operated some years ago. He lost the right eye by an accident when a child, and when I first saw him the left eye was completely hid by a dense piece of flesh. I got rid of this by repeated inoculations with gonorrhœal matter, bringing into view an opaque cornea. There was, however, a small lancet of comparatively clear tissue near the margin, and opposite this I was lucky enough to succeed in forming an artificial pupil. The patient, who was formerly quite blind, I am thankful to say

FIG. 2.

has since had excellent sight, and has been for years able to manage an important business.

In dealing with granular lids and the catarrhal and follicular conjunctivitis which gives rise to it, we must remember that prevention is better than cure, and at once segregate our patients as much as possible. Let them live out of doors; teach them, as Arlt says, "that houses are only to sleep in." Banish, so far as possible, media of contagion. Let each boarder have his own towel, his own soap, and let them wash at the tap, for basins are dangerous. It is very seldom that better-class patients suffer from this disease; but when you are consulted by such persons, it is well, as a purely hygienic measure, to recommend migration for a time to some mountainous district, such as Switzerland, where the disease is unknown. With regard to treatment, I scarify the lids; squeeze out the sago grains; occasionally, but not often, excise the retro-tarsal fold, and apply liquor potassæ, sulphate of copper, or syrup of tannin (nitrate of silver as a caustic does not go deep enough), and deal with bad cases by peritomy and inoculation with ophthalmia neonati or gonorrhœa, or infusion of paternoster bean.

I have here a patient whose conjunctivæ were both completely destroyed by trachoma before I saw her (xerosis), and I have only managed to preserve a little sight by establishing an artificial ankyloblepharon in both eyes. We do not see many cases of trachoma at this institution, I am happy to say, but here is a small boy who is a characteristic example of a form of disease which, like the poor, we have always with us. This lad's mother informs us "that he is very subject to getting his nose stopped up," and "that at first they thought it was weakness which had fallen into the glands of his neck." On examination we find that the nostrils and upper lip are swollen, that the cervical

[1] Sattler says the disease is caused by a microzoon, which he calls the diplococcus of trachoma. It is a small ball, cleft by a tiny line, very like the gonococcus of Neisser, but it may be cultivated in various soils, whereas the gonococcus of Neisser can only be cultivated in the serum of the blood. Speaking on this point, Mr. Power, in his admirable lectures on Bacteriology, says:—"The diplococcus of trachoma has its seat inside the trachoma follicles, but outside the cells, not on the surface, but in the follicles of the conjunctiva; hence the method of squeezing, cutting, or scratching out the follicles is bacteriologically correct."

Digitized by Google

glands are enlarged, and that there is an eruption on the scalp and in the neighbourhood of the right auricle; in short, the boy has got eczema of the skin, and we need not wonder, under such circumstances, if he has also eczema of the conjunctiva, and that is precisely what is the matter: "phlyctenular conjunctivitis," or conjunctivitis scrofulosa, as it used to be called. There are two forms of this affection, the miliary and the solitary. The miliary phlyctens are scattered like grains of sand on the vascular limbus of the cornea, usually come on after measles or scarlet fever, and are masked by considerable general conjunctivitis. The solitary phlycten is about the size of a hemp-seed, is surrounded by a vascular zone, and marked by a small bundle of vessels which radiate outwards towards the equator of the globe. Both forms yield readily to the yellow oxide of mercury ointment, with general treatment, and it is only when the phlyctenular conjunctivitis becomes phlyctenular keratitis that you are likely to have any trouble with the case. Vesication and ulceration of the cornea, however, is a very painful process. Nerve terminals are exposed, photophobia is intense, iritis is sometimes set up, the constitution sympathises, the patient loses his rest, and the ulcers, even when healed, leave scars which may subsequently seriously interfere with vision. In these cases it is necessary to apply leeches, give mercury, put a seton behind the ear, and use hot belladonna fomentations. You will also find that an excellent plan of treatment is to open the anterior chamber with a broad keratome, so as to divide the vessels and nerves at the base of the ulcer. In this way tension is reduced, pain relieved, healing promoted, and the effect may be kept up by daily tapping of the aqueous with a blunt probe; while the ulcer, if obstinate, may be touched with the galvanic or thermo-cautery, after the method so successfully practised by Dr. Nieden of Bochum, Prussia. The worst forms of ulceration of the cornea, however, with which we have to deal are those occasioned by foreign bodies, often aggravated by attempts at removal. I constantly find pieces of corneal epithelium stripped off in the neighbourhood of a small speck that need not have been enlarged. In order to avoid this mischance, you will do well to take a hint from our friends the watchmakers, and use a lens. Fixed in the operator's orbit after the manner familiar to us all, both hands are free, and the foreign body may be readily lifted from its abnormal situation without increasing the area of injury occasioned by its impact. It frequently happens, however, that we do not see these patients until the cornea is clouded and infiltrated with the formation of pus in the anterior chamber, in which case the ulcer should be divided freely across with a thin Graefe's knife, after the manner recommended by Professor Saemisch.[2] Organised lymph and shreds of matter should be gently removed with forceps, and warm fomentations, antiseptics, and atropine or eserine, according to the situation of the ulcer, applied. The chamber may be reopened daily, so long as the pus re-forms, by a mere touch with a blunt probe, and an artificial pupil practised afterwards, if necessary.

When minute fragments of steel have penetrated the cornea, their presence may be demonstrated by this admirable instrument, the electro-magnet, for which we are indebted to Mr. McHardy, Professor of Ophthalmology at King's College. It is not often in these cases that the lens escapes without injury; but I recently extracted a piece of steel through a small incision from the anterior chamber with this fine bent conductor without the formation of cataract or any further damage to the eye. When the lens is wounded it swells, presses forward, and acts upon the iris both as a chemical and mechanical irritant. In these cases we must extract the lens, or if from the nature of the accident this is too great a risk to run, a piece of iris may be removed.

Sight, however, may be seriously affected without any loss of corneal transparency, by mere abnormalities of shape. The cornea may be too flat and the eye too short (hypermetropia), or too long (myopia), or it may be too convex (kerato-globus), or the refraction may differ in different meridians (astigmatism), or it may even project like a sugar loaf (kerato-conus). When the eye is too flat the patient can see at a distance, even through a convex glass; but vision with the naked eye for near objects soon becomes confused; in these cases we must prescribe convex glasses. In cases of astigmatism a combination of cylindrical and spherical lenses is requisite. Iridectomy, in some exceptional cases, is said to do good in kerato-globus, and I am in the habit of treating cases of conical cornea by touching the apex of the cone with the galvanic cautery. With one or two applications the aqueous escapes; the wound in healing, after the manner of burns, contracts; the normal curvature of the cornea is restored; and the cure is completed by making a pupil sideways, and, if necessary, tattooing the scar. With regard to myopia, it is very generally believed that because short-sighted persons can see minute objects with very imperfect light, and because they can read without spectacles at an age when most persons require such aids, that therefore short sight is strong sight. This, however, is a mistake. The vast majority of such patients suffer from permanent organic changes, which, increasing, may at any time damage or even destroy sight. Speaking on this subject, Dr. Williams, the eminent Professor of Ophthalmology in the Harvard University, the oldest University in the United States, says: "Very high degrees of myopia should be recognised as an infirmity deserving careful consideration before assuming the obligations of marriage; for those in moderate circumstances may well hesitate to choose partners, who, though highly cultivated, may probably at middle life become unable to provide for their households or care for their children."[3] Surely that is a serious disease. He adds: "Myopia is one of the gravest affections of the eye: capable of limitation by constant care during childhood and youth; but if not thus limited, likely to be a source of future disability and misery, and *to be handed down as an onerous inheritance to children.*"

Let me epitomise for your guidance a few facts relative to this very important subject. If short sight is not developed before sixteen years of age, it will not be developed at all; if it has not reached a higher grade than one-tenth by twenty, it is not likely (if care be taken) to increase. Higher degrees than this are an ever-present source of danger, disability, and frequent disaster. It is more likely to be developed in weakly children than in others, and frequently makes rapid progress in those who are recovering from illness. It is unknown among savage tribes and tillers of the soil, and is the direct result of a vicious system of excessive education, making its appearance first in the children at village schools in the proportion of about 1 per cent., in schools of higher grade 20 per cent., higher still 40 per cent. Not only the numerical ratio but the intensity of the disease is also increased in direct proportion to the hours spent in study, and the attention of the German Parliament has recently been called to the fact that in some districts where compulsory education has been longest in force, upwards of 50 per cent. of the inhabitants are affected. With regard to treatment, again I say prevention is better than cure; better indeed in this case, for cure is impossible. I see many of my eminent colleagues suggest desks, and fittings, and light arrangements, and props to keep the children's heads in certain positions; but, to my mind, desks and props and fittings do not meet the difficulties of the case. From five to fifteen is the dangerous age—the very period that the School Board have selected for their paternal ministrations; and if the eyes of a child between these ages begin to give way, there is no rational treatment but enforced absence from school; and I do not think myself that such compulsory holiday ought to be regretted by anyone, for children's brains do not grow in proportion to the stuff they cram into them; and, after all, true education is something that a man seeks for himself and finds for himself, and does not usually begin until long after school-days are over. Short-sighted persons, who must complete their curriculum of study for the Church, the Bar, the Civil Service, or other professions, should wear weak concave glasses for reading, so as to be able to hold print about twelve inches from the eye. The light should be good, and come from the back or side, and they should not read or work when lying down, leaning forward, or travelling in a railway carriage. "Seekest thou great things for thyself? Seek them not." To no class does this sage warning apply with greater force and justice than to the myope. Of two brothers, Germans, myopes, and students of medicine, one took heed of this warning, accepted a mediocre degree, and preserved his sight by an out-door life and country practice. The other heeded not, but worked on, and at last achieved distinction, only to find himself, shortly after middle life, unable to walk alone or recognise his fellows. Another condition that

you will find very much benefited by glasses occurs in patients of forty or upwards, who occasionally suffer from marginal blepharitis, the formation of styes, and a feeling of general worry about the eyes owing to reflex irritation from neglect of these aids to vision. Still another is that of chronic invalids, specially women suffering from uterine complaints, painful menstruation, and the like, who spend much of their time on their backs, who read in this unnatural position, and complain of pain and neuralgia whenever they use their eyes. In these cases, in the absence of any marked ametropia, I usually prescribe weak convex glasses combined with abductive prisms, and recommend graduated exercises after the plan first suggested by Dr. Dyer, of Pillsburgh, Pa.

Gentlemen, I have already pointed out to you the great danger of mistaking a slight case of iritis for mere surface irritation,[4] and neglecting to dilate the pupil; the equally great, if not greater, danger of using atropine if the case should be inflammatory glaucoma, a disease which you are so apt to mistake for iritis. I have dwelt on squint and cataract, and pointed out those cases where the eyeball must be extirpated, and those where, in my opinion, opticociliary neurectomy may be advantageously substituted. Let me close this brief and necessarily imperfect sketch by calling your attention to two other errors which I find very frequently committed.

Here is a boy who was sent to me by his surgeon to be treated for myopia, and in truth, on ordinary inspection, you might easily conclude that his imperfect sight was due to that cause; but if you dilate the pupil, or use the ophthalmoscope, you will see at once that he is suffering from congenital cataract. Bear in mind, therefore, that there may be considerable opacity of the lens which is not at all visible on ordinary inspection.

Some years ago I was sent for to operate upon a lady, the wife of a military gentleman of considerable social importance. Two surgeons and a physician were already in attendance, and I was informed that the patient, although advanced in life and very nervous, would prove a good subject for operation, as the cataract was fully formed in each eye. On examination, however, I found that the case was one of simple glaucoma; there was no cataract at all; and the time for beneficial treatment had gone by. Now you will avoid this latter error by remembering that a dusky pupil is quite a natural phenomenon in aged persons, and that it is not at all safe to conclude that, because this appearance is accompanied with failing vision, therefore the case is one of cataract. You must use the ophthalmoscope, or, failing that, trust to subjective symptoms. Of these the most important are limitation of the field and iridescent vision. You will find, if the case is one of glaucoma, that the patient cannot see to the inner or nasal side, or vision is very limited in that direction, and if he looks at a candle or artificial light it is surrounded by red and green colours. You will see what I mean if you will breathe on the glass and look at the street lamp outside. This is an early and significant symptom of glaucoma, and if it does not disappear on rubbing, is not accompanied by evident opacity of the cornea, and does disappear under the influence of eserine, you must be prepared to treat for glaucoma or call in the aid of an ophthalmic surgeon.

Gentlemen, when I was a student I was taught to contemn specialism, and my teacher was Mr. Syme. Now I look upon the late Professor of Clinical Surgery in the University of Edinburgh as probably the first surgeon of the century, and am therefore disposed to regard any opinion of his with exceptional reverence; in this, however, I feel sure he was wrong. Life is so short; art is so long. It is so human to err. You require to see so many hundred patients before you know how to treat one; you require to perform the same operation not only over and over again, but to be always at it, before you can ensure for your patient the utmost benefit that art can afford; so that I feel convinced that if science is to be advanced and humanity benefited, it will be mainly by gentlemen who devote special attention to special subjects, and who place the fruits of their labours at the disposal of the whole profession. It is in the fulfilment of that duty that I am here to-night; that I venture to offer you these few hints, and to assure you that I am highly gratified by your gracious acceptance of the same.

A FORM OF ULCERATION SIMULATING LEPROSY.

BY BEAVEN RAKE, M.D. LOND.,
MEDICAL SUPERINTENDENT OF THE TRINIDAD LEPER ASYLUM.

LAST year Dr. Hale White was kind enough to show for me at the Pathological Society[1] specimens from a case of peculiar ulceration which had been mistaken for leprosy, and admitted to the Trinidad Leper Asylum. Having now three more cases under my care, and not having found this condition mentioned in any article on the diagnosis of leprosy, I have thought that a few notes of these cases may perhaps be of interest.

CASE 1.—P., a Hindoo woman aged thirty-seven. Twelve years' history. The chest and extremities are covered with superficial cicatrices. Above the ankles the dark skin is replaced by light flesh-coloured patches, showing former deep ulceration. The thumbs are intact, but the fingers are strangely distorted. The general arrangement is this: The first phalanges are inclined forwards, the second backwards, and the last phalanges forwards again. The phalangeal joints are more or less dislocated; in some there is ankylosis, in others more or less limited movement. The left forefinger is flail-like, and turned round to one side. The nails are filbert-shaped and slightly split longitudinally. The toes are curved downwards and are somewhat shiny. The toe-nails are worn away. There are superficial ulcers on the feet. There is no tache or anæsthesia anywhere. The toes are hyperæsthetic. No enlarged glands can be felt, and the bones are not markedly thickened. Chest sounds are normal. Magenta shows no bacilli.

CASE 2.—M., a Hindoo woman aged forty-two. Three years' history. The skin of the face and trunk is mottled, but there are no anæsthetic taches. There are old deep cicatrices on the dorsal and ulnar surfaces of the forearms, and over the left ulna are some long punched-out ulcers, exposing bare bone. The hands and fingers are very thin and wasted, but there is no ulceration, destruction of nails, or anæsthesia. On the front of the legs, upper surface of the feet, and left sole are old cicatrices and punched-out ulcers. Dead bone has been removed from shaft of left tibia. The toe-nails are intact, and sensibility is good. No enlarged glands can be made out, and the chest signs are normal. The patient is still extremely wasted, but has improved much since admission. Magenta shows no bacilli.

CASE 3.—D. J., a Negro aged forty-four. Five years' history. There are pale patches on the cheeks, joining beneath the nose; they are not anæsthetic. Trunk normal. The fingers of the left hand are partly ankylosed, the last phalanges being turned backwards towards the dorsum. On the extensor surfaces of the fingers are hyperæsthetic cicatrices. The third and fourth fingers of the right hand are also becoming distorted. The nails of both hands are long, intact, and more or less filbert-shaped. The finger-pulps are hyperæsthetic. Over the left external malleolus is a superficial ulcer about two inches long, nearly cicatrised. The toes are flexed, ankylosed, but not anæsthetic. Nails intact. There are scars on the dorsum of the right foot. Harsh breathing at left apex and nummulated sputum. Enlarged cervical glands on left side. Patient much wasted. Magenta shows a few bacilli in discharge from ulcer.

The main differences from leprosy are seen to be three:—1. There is no anæsthesia of fingers or toes. Indeed, in Cases 1 and 3 there is very marked hyperæsthesia. 2. There are no anæsthetic taches. In Cases 2 and 3 there is more or less leukoderma, but sensation over these patches is perfect. 3. There is no loss of phalanges or deformity of nails. In Case 2 the toe-nails are worn away, but this appears to be simply mechanical and very different from the destruction and deformity common in leprosy. The presence of bacilli in the last case is not to be wondered at, seeing that the patient is the subject of advanced phthisis.

The cause of this form of ulceration is obscure. On looking through the literature of tropical disease, it seems to me that this ulceration presents a remarkable analogy to the "parangi" disease of Ceylon as described by Gavin Milroy.[2] He says: "The characteristic features of the malady are diverse forms of skin disease, ulcerations of the surface in

[1] Path. Soc. Trans., vol. xxxviii., p. 544.
[2] Endemic Diseases of India (Fox and Farquhar), p. 95 *et seq.*

Digitized by Google

different parts, and frequently also affections of the bones and joints, leading on, in bad neglected cases, to emaciation, exhaustion, with much suffering and death. ..... Sometimes it exhibits all the appearance of inveterate lepra." He remarks also on its resemblance to some endemic forms of disease in the Western hemisphere, and Fox and Farquhar comment on its relation to Delhi sore and its allies. I would venture to suggest that the above cases are Western analogues of these Eastern diseases.

Trinidad.

ON SOME CLINICAL FEATURES OF GRAVES' DISEASE.[1]

BY SIMEON SNELL,

OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY AND TO THE INSTITUTION FOR THE BLIND; LECTURER ON OPHTHALMIC SURGERY AT THE SHEFFIELD MEDICAL SCHOOL.

IT is far from my intention in this paper to dwell on the whole train of symptoms which go to make up the disease recognised under the name of exophthalmic goitre. I shall limit myself to certain features of the affection, illustrated by cases occurring in my own practice. Let me in the first place direct attention to the eye symptoms. They are three in number—viz.: exophthalmos; Stellwag's symptom, or retraction of the eyelids; and Graefe's sign, or loss of the coördinated movement between the upper eyelid and the eyeball, and thus if the globe is turned downwards the eyelid does not follow fully, but leaves a zone of sclerotic visible above the cornea. The relationship of these symptoms, and especially the latter two, to Graves disease is the question which I wish first to discuss.

Dr. Wilks, at the discussion on this subject at the Ophthalmological Society in May last year (1886), said that "increase of cardiac rapidity he regarded as a primary and necessary symptom; quickened cardiac action, combined with exophthalmos and emaciation, or with enlarged thyroid, he would regard as characteristic." The general experience seems to be that it is exceedingly uncommon for the cardiac symptoms to be absent. Trousseau and most writers believe that they preceded other symptoms. Graefe held a different opinion. It is not difficult, however, to find a reason to account for this diverse experience; for physicians would naturally be consulted in the first place by those in whom the cardiac symptoms were primarily pronounced, and Graefe by those in whom the first in order were the ophthalmic. At the same time Sattler, from the same standpoint as Graefe, says: "It belongs to the rarest exceptions for the cardiac palpitation not to form the first symptom." Sooner or later the eye symptoms make their appearance, and the constancy with which they occur is generally recognised, and their presence often regarded as pathognomonic. At the same time, cases have occurred in my practice which lend support to the belief that no infrequently the eye symptoms—and I mean especially the lid signs—occur among the early indications of the disease. It is also possible that their occurrence has been overlooked in cases where the observers, having failed perhaps to note the fulness of the globe, have not examined for less apparent lid symptoms.

A woman who is under my care, and whom I have introduced this evening, I take to be one of the character I have mentioned, with the early development of the characteristic signs of the lids. Her age is forty-five, and she saw me at the infirmary on Dec. 10th for the first time. Six months ago, after a severe headache, she first noticed anything unusual about her eyes. Then, as at the time of coming to the infirmary, she supposed it was the left eye that did not open sufficiently, and that the right was perfect. She has been a widow for eighteen years; the catamenia have been very irregular since then, and menstruation has been entirely absent for eighteen months or more. She has had a good deal of anxiety about the success of a son during the last twelve months, and has been "nervous." She does not admit that she is thinner than usual. Examination at once disclosed that the faulty eye was not the one the patient supposed. The left eye was normal, and only apparently more closed in contrast to the altered state of the right. On this (right side) retraction of the upper eyelid (Stellwag's symptom), causing a widening of the palpebral fissure, was present; also when the patient looked down the relation of descent between the eyelid and the globe was broken, and a zone of sclerotic left bare above the cornea (Graefe's sign). There was no real exophthalmos present; the widening of the palpebral fissure would account for any little apparent prominence. Vision in each eye was normal, $\frac{20}{20}$, and the eyes were free from disease; on the right side there was venous retinal pulsation. The thyroid gland was perceptibly enlarged, and the right side more so than the left; it had not, however, attracted the patient's attention. Cardiac symptoms were absent; pulse 80; "flushings" had not been experienced; and there was also an absence of the "flurried fussy manner" of a complete case of Graves' disease. Urine: sp. gr. 1020; no albumen; no sugar. Notwithstanding the absence of the third cardinal symptom and the monocular character, I do not see how this case can be regarded as otherwise than as one of exophthalmic goitre. It is possible the other symptoms may develop later.

Not long ago, too, a young woman came under my observation with the retraction of lids (Stellwag's sign) and also Graefe's symptom, with some amount of exophthalmos. The other symptoms were not marked; and though I was myself disposed to regard the thyroid as a little goitrous, it was at all events so little that others disagreed with me. Dr. Dyson saw her at this time, and she has been under his care since, and he has kindly consented to her coming here this evening, as the other cardinal symptoms have since developed. The patient has reminded me of the interesting fact that she did not come to the infirmary respecting her condition at all, but only accompanied a relative, and that I, noticing something about her eyes, examined her and found the condition I have stated. It had never attracted her attention before. The eye symptoms are more marked on the left side.

About a year ago, also, I saw a young lady with an absence of all symptoms of Graves' disease, except a nervous irritability, and that in the right eye Graefe's symptom, and especially Stellwag's, were both well marked. There was no exophthalmos. The left eye was normal. This case caused me at the time and since to reflect whether these symptoms may occur independently of exophthalmic goitre, or indeed in a case which does not actually pass into the train of symptoms recognised under that disease; especially, moreover, as in this case treatment affected more than it usually does in Graves' disease. Bromide of potassium was used without much benefit; but the constant current, with tonics and change of air, were followed by marked improvement. No other definite cause in the way of diseased teeth &c. was found. She remains now practically well at the lapse of ten months since discontinuing treatment.

A still more interesting case is that of a miner aged thirty-six, whom you have seen, and who is suffering from well-marked miners' nystagmus, the oscillations being both rotatory and of a to-and-fro character, and the movements being increased by placing the head in an oblique position, as well as by the other means that generally aggravate the oscillatory motions in the nystagmus of miners. The interest for our present purpose lies in the fact that there is also present retraction of the eyelids (Stellwag's symptom), rendering the sclerotic bare round the cornea, and very marked Graefe's sign. He appears, moreover, to possess some control over this condition, for he can lower the eyelids to the cornea and present an almost normal appearance; and this does not seem to bear any very exact relation to the nystagmus. The eye movements, though worse at some times and in certain positions, never cease. It is doubtful whether there is any real exophthalmos—probably not; nor can the thyroid be considered as enlarged. There is a complete absence of all other symptoms of Graves' disease.

At the discussion at the Ophthalmological Society Mr. Lang read an epitome of six cases in which unilateral lid phenomenon, without proptosis, was associated with no other evidence of Graves' disease except slight enlargement of the thyroid in two cases. In four, however, paresis of the orbital muscles was present. Dr. Hughlings Jackson mentioned also that he had observed Graefe's sign in a case with no Graves' disease. An immense number of cases of miners' nystagmus have at one time or other passed under my observation, but such an association of lid symptoms as witnessed in the case related is unique in my experience.

Fortunately, notwithstanding the degree of protrusion of eyeballs which in some cases occurs, sloughing of the cornea

[1] Read before the Sheffield Medico-Chirurgical Society, Dec. 23rd, 1886.

Digitized by Google

is a very rare occurrence. No such result has occurred in my practice, though two cases have come under my care in the infirmary—one not long after the suppuration had commenced, and the other only after the globes had become destroyed.

The first case was that of a young woman, unmarried, aged twenty-three, and she was admitted into the Fir Vale Workhouse on Nov. 14th, 1882, where our present house-surgeon, Mr. C. F. Coombe, saw her, whilst acting as resident medical officer to that institution, and he has kindly supplied most of the particulars which follow. At this time she presented well-marked enlargement of both lobes of the thyroid gland, with great prominence of the eyeballs. She had frequent attacks of very severe palpitation, and systolic bruits were heard both at the base and apex of the heart. During the next fortnight the exophthalmos increased considerably, and became so great that she could not cover the globes with the eyelids. Ulcers appeared on the cornea, spreading and assuming a sloughing character. On Dec. 2nd she was admitted into the Sheffield General Infirmary, under Dr. Bartolomé, and on the 4th was transferred to me. Shortly after admission she was attacked with erysipelas (facial), and died on Dec. 12th. No post-mortem examination was allowed. When she came under my observation both corneæ were extensively sloughed, altogether past recovery. No cause was assigned for the disease, but her condition from the first when under my care was such as to preclude the possibility of taking detailed particulars of her case.

The second instance was in a married woman aged forty. She was admitted into the Sheffield General Infirmary in May last (1886) with both eyeballs destroyed by sloughing of the corneæ. The thyroid gland was markedly enlarged; there was palpitation and a loud hæmic murmur (basic). There was the excitable nervous disposition met with in patients having Graves' disease, and "flushings" were likewise experienced. The eyelid symptoms were obscured as a consequence of the sloughing of the eyeballs, but Stellwag's symptom (retraction of eyelids) was undoubtedly present.

A remark occurs to me respecting the condition of the thyroid gland in these cases of exophthalmic goitre. Frequently one lobe is larger than the other, and in recorded cases in which the side is particularised, the right is the one referred to. Anatomists, however, state that the right lobe is normally larger than the left. Have clinicians borne in mind sufficiently the anatomical fact?

Monocular cases.—Generally speaking, Graves' disease is bilateral, though not unfrequently it is more marked on one side of the body than the other. Several cases are on record in which the eye symptoms have been confined to one eye. Dr. Hill Griffiths stated at the Ophthalmological Society that the eye symptoms in his thirty cases were bilateral in twenty-three instances; in four the right only was affected, and the left in three. In addition to the patient already referred to (No. 1), I have notes of two other cases.

The first occurred in a female, aged fifty-four, who consulted me in 1877. She suffered greatly from palpitation; pulse 150. Exophthalmos (right side); lids closed over the eyeball but not easily. Had only been married recently; her health was poor, and she had had a great deal of nursing; slept badly. Menstruation ceased a year ago. The thyroid gland was enlarged; my note does not say whether equally so, or whether one side was larger than the other. I only saw her a few times.

The next case was a domestic servant aged twenty-three, who was first seen in June, 1884. For three or four months the left eye was noticed to be prominent, and had been much worse during the last two months. The retraction of the eyelid (Stellwag's symptom) was well marked, and had been so for two months, the patient stating that the eye had been as wide open during that period as it was at the present time. The eye was prominent, and Graefe's sign, loss of coördinated movements in descent of eyeball and upper eyelid, was present. The eye was myopic; V = fingers, and was but little improved by any – glass. There was divergent squint; there were extensive choroidal changes in the region of the macula. She had been aware of the badness of vision with the eye for many years. The right eye was hypermetropic, and the symptoms present in the left were absent. She suffered a great deal from palpitation; there was a hæmic cardiac bruit, audible with first sound at base and into the neck. Goitre was present, and had only been noticed two or three weeks—not large but distinct, and, if anything, the right was the larger side. No shock or other apparent cause. Menstruation was frequent. She was introduced at one of our meetings some time after this. She remained under my care, and in the following November it seemed as if the right eye would also become affected; but it never did so. At the end of twelve months the following note was made: "She has been at Scarborough, and is in much better health. The prominence of the left eye is now very much less, but she thinks it is not quite as it was before the attack commenced. The right eye is quite good. No flushings now, nor palpitations. Has lost her nervousness. Catamenia regular."

A theory to be satisfactory must be able to account for the whole train of symptoms. The one that seems to fall in best with this condition is the central lesion theory brought forward by Sattler, and which has found in these islands a very able advocate in Dr. W. A. Fitzgerald of Dublin.[2] Briefly, Sattler assumes a lesion of the vaso-motor centre that presides over the vaso-motor nerves of the thyroid gland and orbital tissues, and it is inferred from the frequent association of goitre and exophthalmos that these centres must be close together. The cardiac symptoms he ascribes to lesion of the cardio-inhibitory centre for the vagus, and Graefe's symptom is explained on the assumption that there is a centre governing the associated downward movements of the eye and eyelids, just as the associated movements of both eyes. He coincides in Stellwag's opinion that the widening of the palpebral opening is due to a lesion of the reflex centres, which are set in motion by stimuli from the retina, cornea, and conjunctiva. The experiments of Filehne on the restiform bodies have given considerable support to this theory, these being the parts through which the nerve paths from the vaso-motor centres and vagal centres pass. In one case he succeeded in inducing the three cardinal symptoms, and in the others a varying association of the symptoms. Moreover, the interesting association of diabetes in some cases of Graves' disease is well known, and it is worthy of notice that the region described as the diabetic puncture is close to the vaso-motor area. Do not the cases referred to in this paper lend support to such a central theory? In other diseases we are accustomed to regard a lesion as spreading and gradually encroaching on contiguous areas, either by direct extension or by irritation of surrounding tissues. May we not, therefore, regard the cases in which the lid symptoms are among the earliest as instances in which the lesion has only affected the centres governing the coördinated downward movement of the globe and eyelid, with the lid reflexes generally closely associated, the other centres becoming implicated later on, with a consequent further development of symptoms? Or are there cases which stop at a lesion of the lid centres?

COLOTOMY FOR MALIGNANT DISEASE OF THE RECTUM, WITH NEARLY PERFECT CONTROL OVER THE ARTIFICAL ANUS A YEAR AFTER THE OPERATION.

BY HARRISON CRIPPS, F.R.C.S.,
ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

THE patient, a woman aged fifty, was kindly placed under my care at the hospital by Dr. Griffith. I am indebted for the following notes to Mr. Balgarnie, her dresser.

The woman was admitted on Dec. 15th, 1885. She dates her present illness from the spring, when she first noticed pain in the lower part of the back, and soon afterwards pain during defecation. The character of her motions gradually altered, becoming smaller in size, and at times flattened and generally tinged with blood. The frequency of her stools increased, at first to three or four times a day, but latterly much more often. She has been getting thinner, and at times has much severe pain, which she described as like "labour pains."

The patient on admission looked weak and anæmic, with a feeble pulse. She had nearly constant pain, and was much distressed by a troublesome diarrhœa, having to go to stool as often as ten or twelve times in the night. The act of defecation was very painful, and nearly always attended by loss of blood. On examination the anus appeared healthy, and on

[2] Dublin Medical Journal, 1883.

Digitized by Google

ntroducing the finger the mucous membrane for about three inches felt smooth and natural. The finger then came in contact with a mass feeling not unlike an enlarged cervix uteri. Around this was a cul-de-sac, deeper posteriorly than anteriorly. The mass itself was hard and nodular. The opening through it would only admit the tip of the finger, and the bowel at the constricted point was firmly fixed to the surrounding structures.

The patient, not wishing then to stay in the hospital, left, but was readmitted on Feb. 1st. She had become weaker, and her symptoms had increased since her discharge. The mass also had grown considerably, and could now be felt to be within an inch and a half of the anus. On Feb. 8th, 1886, the case being considered unsuitable for excision, lumbar colotomy was performed by Mr. Harrison Cripps. The various layers between the skin and the lumbar fascia were purposely not divided on quite the same level, and the opening in the fascia was considerably above that in the skin, so that the bowel when drawn out ran obliquely for a short distance between the skin and the fascia. The wound united by first intention. No motion passed through it for a week. During the next six weeks a certain amount of fæces passed through the rectum as well as through the wound. This gradually ceased, and when she was discharged in March everything passed through the artificial anus. She improved very much whilst in the hospital, and was comparatively free from pain.

April, 1887.—The patient is not only alive, but wonderfully improved; and notwithstanding that the local growth has made some advance, her general health and strength is far better than it was a year ago. She is no longer troubled with diarrhœa, but has one good motion daily through the artificial anus, and she has been able to attend as usual during the year to her domestic duties. The artificial anus readily admits the forefinger, and the mucous membrane is exactly on the level of the skin. There is no sign of cicatricial tissue round the orifice, which is perfectly soft and dilatable. The patient knows when she is going to pass a motion, which she has the power of controlling, there being no involuntary escape. In fact, the patient herself says she is no more troubled with the artificial anus than when the opening was in the natural situation. The patient was shown at the Medical Society.

After carefully watching a large number of cases of rectal cancer, in some of which colotomy had been performed, while in others nature had been allowed to take its course, I do not hesitate to pronounce strongly in favour of the operation. The relief to the symptoms is very marked, the constant diarrhœa and tenesmus which forms so frequent and distressing a complication being entirely relieved. The downward course of the patient is certainly made far easier, and the miserable termination of life by obstruction or perforation prevented. Moreover, I feel confident that the progress of the growth is retarded in consequence of the bowel acquiring physiological rest by the cessation of its function. That the rapidity of malignant growth depends much on the activity and consequent blood-supply of the organ affected admits of no doubt, and as an example may be instanced the relative rapidity with which cancer grows in the breast of a pregnant or suckling woman. So that, apart from life being indirectly prolonged by the relief which colotomy affords to distressing symptoms, I feel confident that the growth itself is often retarded, and rendered comparatively quiescent when the rectum is placed at rest by the operation. Colotomy is in no sense a rival operation with that of excision. Excision is doubtless the proper operation when the disease is within easy reach and still confined to the walls of the rectum, thus admitting of a free and complete removal. Such favourable conditions are, however, unfortunately exceptional, the disease either having commenced too high or spread too far by the time the case has come under observation to admit of local interference. The practical question that arises is as to what period in the course of a case of rectal cancer colotomy should be performed. In answering this question, I am in complete accord with Mr. Reeves, who advocates the performance of the operation so soon as symptoms of stricture become prominent. The troublesome diarrhœa, pain, tenesmus, and blood-stained discharge owe their origin far more to the retention of scybala above the contracted part than to the actual disease itself. To wait until the unfortunate sufferer is at death's door, worn out by the constant discharge, or by the actual occurrence of complete obstruction, is not only to have deprived the patient of the benefit of the operation, but to perform it at a time when it becomes a dangerous procedure. The operation, if performed before the patient is much reduced in strength, has but little risk; indeed, I can say in my own practice that I have hitherto had no death as the immediate result of the operation when performed for malignant disease. It is essential, if the patient is to derive full benefit from the operation, that care should be taken to prevent the opening from contracting. It is of great importance, with this view, to get union of the bowel with the skin by first intention. If this occurs there is little or no tendency to contract. On the other hand, if the bowel falls away from the skin the granulating tissue with which the interval is occupied is nearly sure to contract on healing. In one case in which I recently operated half the benefit was lost from this cause, for, on seeing the patient two months after the operation, the opening would barely admit the finger. If there is any tendency to contraction, it is best prevented by allowing the wound to heal over a full-sized plug. I regard it as a great advantage to make the opening through the abdominal walls as valvular as possible, and this is best accomplished by making the incision through the skin considerably lower than that through the fascia. If the opening is made in this way, and care taken during the healing process to prevent contraction, the patient will have little or no difficulty in managing the artificial anus. In the case recorded, the part was perfectly clean, the patient had one motion daily, and had control over the bowel, while she was able to do her daily work without annoyance of any kind.

Stratford-place, Oxford-street, W.

EXTIRPATION OF RUPTURED UTERUS.

BY E. C. ANDREWS, B.A., M.B., B.C. CANTAB., &c.,
SCHOLAR OF ST. JOHN'S COLLEGE, CAMBRIDGE, AND SENIOR OBSTETRIC RESIDENT AT GUY'S HOSPITAL.

ON September 12th, at 5.30 P.M., one of the extern midwifery attendants was called in to attend the fifth labour of Mrs. S——, who was said to have had pains for twenty-four hours. She was a delicate woman of short stature and her previous confinements had all been normal. Vaginal examination showed the os fairly dilated, membranes unruptured, and the vertex presenting resting on the pubes. The pains were of medium frequency, and apparently those of the first stage of labour. At 6.30 P.M., the pulse being then about 120, the membranes ruptured, and the pains increased in force and frequency, culminating about 8 P.M. in exceedingly strong expulsive efforts, which affected the progress of the head but little, if at all. Immediately after these the patient complained of intense pain in the stomach, there was marked collapse, and all labour pains ceased.

I was now summoned to the case, and found the patient nearly pulseless, pale, and exhausted, but quite conscious, and the head on the brim of the pelvis and rather movable. Recognising the urgent necessity for immediate delivery, I directed the abdomen to be well supported by the extern, introduced the long forceps, and proceeded to deliver the child. No difficulty was experienced in the introduction of the blades, and but very gentle traction was required. Fearing that the perineum might rupture, I withdrew the forceps as soon as the head was well down upon it, but instead of expulsion taking place, the head receded into the vagina. I again applied the forceps, and delivered without further difficulty. The child was a large one, weighing 9½ lb., was stillborn, and the delivery was followed by a gush of blood, though the uterus appeared firmly contracted. After waiting a few minutes, finding that the placenta did not come away, I introduced my hand and found that it passed through a rent in the uterine wall into the abdominal cavity. Following up the cord with my fingers, I discoverd the placenta in the abdominal cavity above the uterus, and removed it without difficulty. An injection of two-thirds of a grain of ergotine was now administered. The pulse was quite imperceptible and the patient apparently dying. An hour later the patient had rallied considerably; the pulse was 140, of fair force, and there had been no further hæmorrhage from the vagina. About 10.30 P.M., however, the pulse was much feebler, and coils of intestine had come down through the rent into the vagina.

Digitized by Google

In the temporary absence of Dr. Galabin, I consulted with my colleague, Mr. A. E. Price, and we agreed that the patient's only chance lay in the immediate performance of abdominal section. Ether was accordingly administered, and, with the assistance of Mr. Price and Mr. F. R. B. Bisshopp, I proceeded to open the abdomen by an incision in the median line extending from a quarter of an inch below the umbilicus to a quarter of an inch above the pubes. Each layer was in turn divided on a director until the peritoneal cavity was reached, and then, passing my hand downwards and to the left over the surface of the uterus, I found a large, ragged tear in the left and front of the organ, while the abdominal cavity contained a very large quantity of blood. The position and extent of the rent, together with the extreme laceration and thinning of its edges, determined me to remove the entire uterus and appendages rather than attempt to unite the tear with sutures. I accordingly lifted the uterus out through the abdominal wound, placed a double ligature round both broad ligaments, and divided them. Then carefully clamping the cervix below the rent, I transfixed the pedicle with a needle and tied each half with a double ligature, afterwards carrying one of the ends round the whole stump. Cutting through the pedicle above the clamp, I now removed the uterus. The peritoneal cavity was sponged out as completely as possible, and the pedicle brought forward and fixed with harelip pins to the lower end of the abdominal wound. I then closed the upper part of the incision with wire sutures, and applied the usual gauze dressings. During the whole operation, which lasted three-quarters of an hour, there was but very little hæmorrhage, and during the earlier stages the patient's condition was all that could be desired. Towards the end, however, she gradually sank, and died soon after the operation was completed.

Subsequent examination of the uterus showed the organ to be of the normal size after parturition, and weighing roughly twenty-four ounces. The rent extended from the attachment of the upper part of the left broad ligament vertically downwards to the lower third of the cervix, and then passed transversely across the anterior cervical wall to the right side, its total length being nearly six inches and a half. The edges were much lacerated and very thin, and in the surrounding tissue there was a good deal of blood extravasated. The placental site was on the fundus and posterior wall, and the muscular tissue was firm and well contracted, showing a healthy structure on microscopic examination. In the right ovary there was a characteristic corpus luteum of pregnancy, and in the left two minute cysts.

As far as I am aware, the uterus and appendages have not before been removed for a rupture of that organ. I have stated above the reasons which led me to prefer this operation to any attempt to sew up the tear, though I opened the abdomen with the intention of doing so. Immediately after delivery the patient appeared to be sinking much too rapidly for any operative interference to be attempted. As my notes show, she rallied from the shock, but only to sink again from hæmorrhage into the peritoneal cavity as soon as the reaction was well established. That this hæmorrhage was the fatal factor in the case I have not the least doubt. Not having a serre-nœud at hand, I had to make use of an ordinary ovariotomy clamp, but I feel sure that the former is much the more suitable instrument. In conclusion, I believe that such an operation as I performed gives a chance to an otherwise hopeless case, and that it should be undertaken without hesitation under such circumstances.

Prince Arthur-road, N.W.

A REMARKABLE CASE OF COMA DUE TO MALIGNANT PUSTULE (ANTHRAX).

BY F. J. REILLY, L.R.C.P. ED., M.R.C.S.

ON Tuesday, April 12th, at 9 A.M., I was sent for to see Mr. H. I. S——, residing in Hackney. I found him in bed, totally insensible and convulsed. His case presented some of the appearances of irritant poisoning, such as vomiting, head fixed rigidly backwards, and the muscles of the trunk and limbs having tonic and clonic spasms. The breathing was stertorous, and he was totally unconscious, with insensitive conjunctivæ. On careful examination, I found his temperature was 105°; pulse 140, soft and compressible. I also found on the nape of his neck a dark livid black spot about the size of a threepenny-piece, with hard base 2½ in. by 2½ in., and then came to the conclusion that it was blood-poisoning of the most virulent character. I then wired to Dr. Angel Money, who kindly came directly and suggested an operation of removing the whole of the affected part at the nape of the neck, which I immediately did; this operation relieved the patient's convulsions considerably, but he died five hours after in coma. There was no albumen in the urine and no sugar, and nothing to suggest either Bright's disease or diabetes. The patient had never been ill in his life. He had been at business on the previous Saturday. In the evening he played whist with his friends, about a mile from his own residence, partaking of a hearty supper, and then walked home between 12 and 1. He went to bed and slept well. On Sunday morning he took his breakfast as usual, and was only noticed to complain of feeling chilly. He wore an overcoat, and did not put on his collar because of the "boil." Took his dinner, and in the evening amused his children by reciting. He went to bed and remained there until 4 P.M. the following day, when he got up and came downstairs complaining of great prostration. He returned to bed at 7 o'clock, and all night was most restless. At 6 A.M. he got up and made some tea, took a cupful and gave his wife one; at 8 A.M. he got out of bed and fell down from what I consider to be syncope. He so far recovered from this to get back to bed without assistance; becoming insensible, I was then sent for, and found the condition above stated.

The most important feature about this case is that Mr. H. I. S. was a tanner, employing about seventy men, and his long experience made it important that he should superintend the sorting of hides, which he did on Saturday, and it is not unreasonable to suppose that from this source the contagion was contracted. The Government ought at once to take some steps, now that anthrax is so prevalent amongst animals, to make an immediate order that all their skins and carcases should be cremated. Dr. Angel Money took the portion removed away, promising to mount and examine for bacillus anthrax. A preliminary examination has demonstrated the presence of a few short rods having the characters of the bacillus in question.

Victoria-park-road, Hackney.

NOTE ON EXTEMPORISED INHALERS.

BY THEODORE MAXWELL, M.D., B.SC.

FEW practitioners who have been in the habit of employing inhalations in diseases of the respiratory organs would willingly give them up for all the draughts and mixtures that have been invented. Why, then, do so few prescribe inhalations? Probably because the use of the various instruments in vogue is attended with inconvenience, and the patients, as a rule, object to wearing a hideous and uncomfortable semi-mask or to lean over an earthenware jug with a mouthpiece for some time each day. In some cases, too, as with chloride of ammonium, the inhalers to be had are both cumbrous and expensive. A little ingenuity will enable the practitioner to obviate many of the objections to prescribing medication in this form. For example, is it desired to inhale the vapour of a few drops of volatile liquid, such as creasote and ether dissolved in spirit? Take a piece of indiarubber tubing about three-eighths of an inch in diameter, and two inches and a quarter in length; cut out three-quarters of the circumference of the middle third; there will then be left two tubes, three-quarters of an inch long, joined by a mere band also three-quarters of an inch long. Roll up a little strip of blotting-paper, and insert into each of the tubes. This will absorb from three to five minims of liquid dropped into each tube. All that has then to be done is to bend the apparatus into the form of a U, and insert it into the nostrils, the indiarubber band resting against or below the bridge of the nose. The patient should inspire by the nose and expire by the mouth. This is, in fact, a simplified—may I say an improved—form of Cozzolini's inhaler mentioned in THE LANCET of March 19th.

Again, chloride of ammonium vapour is simply invaluable in winter cough with so-called asthma, a few puffs from the apparatus described and figured by Dr. Kendal Franks in

Digitized by Google

THE LANCET of January 22nd being frequently sufficient to afford immense relief; but this apparatus (Vereker's), as well as another of Lee's, is cumbrous, and too expensive for poor patients. Besides, such goods are not to had in ordinary chemists' shops in country towns. The apparatus itself may be improvised with three wide-mouthed bottles and a few pieces of glass and indiarubber tubing; the difficulty about the Y-shaped tube, which only a practised glass-blower can make, can be got over by leading the ammonia and hydrochloric acid separately into the wash-bottle, whose cork must thus have three holes. The gases combine quite as well in the water, or after they have passed through it, as they do in the leg of the Y-shaped tube. But there is a much simpler plan still, which can be extemporised in any surgery in two minutes. Remove the piston and cork from a glass syringe (male or female), the larger the better; tear, so as to fit the tube loosely, four pieces of sponge; damp them; insert one down to the end; put, say, a dozen drops of strong hydrochloric acid on the second, and push it down near the first; then insert the third, which is simply damped; on the fourth drop, say, a dozen minims of dilute solution of ammonium, insert it, and finally a perforated cork. Tell the patient to smoke the "patent cigar" from the nozzle for five minutes. If the sponges have not been too tightly rammed in, there will be no difficulty, and the peculiar white cloud will issue from the mouth or nostrils at each exhalation. I find it necessary to explain to patients that the "smoke" is not merely to be sucked into the mouth, but drawn deeply into the chest. This "patent cigar" can be used by several patients successively in the surgery, but the charge will not last long. After use, the sponges may be withdrawn with an old pair of dressing forceps, and recharged when required again, as the sponge containing the acid soon gets spoiled; pumice-stone or asbestos is better. Before letting a patient inhale, the "cigar" should be cautiously tried, lest either the acid or the ammonia should be too strong.

GUY'S HOSPITAL.

TWO CASES OF COLOTOMY FOR MALIGNANT DISEASE.—FRACTURE OF THE TIBIA DUE TO NECROSIS.—REMOVAL OF FOREIGN BODY FROM THE ANTRUM.

(Under the care of Mr. BRYANT.)

THE cases in which colotomy was performed present very good examples of forms of disease in which the employment of this operation gives very great relief from the more urgent symptoms and also prolongs life, the malignant disease being no longer in a constant condition of irritation, and growing less rapidly. It is rare to find fracture of the tibia due to necrosis, and not unfrequently the condition of the parts compels amputation. The fourth case shows the necessity of careful inquiry and examination where these sinuses may possibly be due to a foreign body.

Recto-vesical fistula due to malignant disease; colotomy (two stages); pins used. (From notes by Messrs. E. Deane and A. G. W. Bowen.)—E. P——, aged forty-six, was admitted on January 18th, 1886. Has had very few illnesses, and gives no history of any intestinal trouble or inflammation; she is married, but has had no children; she has had one miscarriage. Nearly four years ago she noticed that she had trouble with her urine, which she passed frequently and in small quantities, accompanied with great pain. A few weeks later she noticed fæces in the urine, during micturition the stream would be stopped by lumps of fæces which came away like pieces of string. She also noticed that she passed flatus per urethram. During this time she had much difficulty and pain in passing her motions, which were smaller than normal, never exceeding the diameter of the forefinger. The menses became irregular about six years before admission, and ceased entirely between four and five years ago. On Dec. 24th, 1885, the patient lost a large quantity of blood, the flow commencing from the vagina and afterwards coming from the rectum as well; previous to this she had very severe pain in the lower part of her body, and a good deal of slimy matter was passed with the motions. She complains of a good deal of pain in her back and loins. She has lost flesh considerably of late, and cannot sleep well owing to pain and having to get up frequently to pass urine. More fæces pass in the urine on straining or taking severe exercise, or when the bowels have not been open for some time. She says she passes white fibrous-looking lumps in the urine as well as fæces. Urine slightly acid; sp. gr. 1018; contains a small quantity of lithates, albumen, and pus, but no blood or sugar.

Jan. 21st.—On examination per vaginam, the uterus is found to be fixed and slightly flexed forwards. On examination per rectum, nothing very definite can be reached by the finger, but it seems to just reach a hardish, nodular, movable mass.

27th.—She is quite certain that fæces are still passed per vaginam, but none can be found in the urine.

29th.—The patient complains of very severe headache, with occasional shivering fits and sore-throat. Five grains of quinine were given.

Feb. 3rd.—With the aid of the microscope numerous pus-cells and some epithelial cells can be seen in the urine, which has a distinctly fæcal smell.

11th.—Condition of urine not improved.

12th.—Chloroform having been given, Mr. Bryant made an oblique incision three inches in length and about two inches and a half above the crest of the ilium on the left side, dividing fat and muscles down to the transversalis fascia. The bleeding was then stopped by twisting a few small vessels. The bowel was then inflated with air, and on dividing the fascia a large coil of bowel presented through the wound. This was fixed there by passing two long hare-lip pins through the integuments below, transfixing the colon through rather more than half its diameter, and passing out through the integuments above the wound; the bowel was not opened. The posterior end of the wound was then closed by two silk sutures, and the whole dressed with iodoform gauze and terebene oil.

13th.—A grain of opium was given last night. The patient was sick several times after the operation. She complains of a good deal of pain around the wound. The discharge had soaked through the dressings, which were renewed. Fomentations over abdomen, containing equal parts of tincture of opium and belladonna liniment.

15th.—The pain was less and the fomentations discontinued. Wound looking well; dressed to-day. Urine still contains pus. Patient has passed flatus and fæcal matter since the operation.

17th.—The bowel was opened to-day with a tenotomy knife. The patient experienced no pain then nor later when the needles were withdrawn.

20th.—The patient complains of flatus still coming per vaginam when she passes urine.

March 1st.—Nearly clear-coloured urine; a deposit of mucus; only a trace of albumen; very few pus-cells.

3rd.—Flatus has not passed through the vagina since last week, but there is still a little discharge per anum.

11th.—There is a red circular area around the aperture of the wound, about an inch wide from its circumference to its edge.

15th.—The redness has entirely disappeared.

On the 17th there was some pain during micturition. Flatus and fæcal matter had ceased to pass per vaginam. A colotomy belt was ordered on the 22nd, and she left much improved on the 31st. Her last report three months ago was satisfactory.

Malignant growth of pelvis (sarcoma?) involving rectum: colotomy. (From notes by Messrs. Bindley and C. J. Fuller.) C. L——, aged twenty-six, a clerk, was admitted on May 21st, 1885. The patient states that his father died of dropsy and his mother of cancer. Has one brother and three sisters; one of his sisters was operated upon by Mr. Bryant for periosteal sarcoma of the lower jaw fifteen years ago. He enjoyed fairly good health until May of last year; he then suffered from hæmorrhoids for two or three

Digitized by Google

months. Since Christmas he has had diarrhœa badly. During the last two or three days he says that he has felt a burning pain at the anus, and that mucus and blood have passed.

Examination on admission.—On examination per rectum the anus was found to be unduly patent; in front of the rectum, in about the situation of the prostate and base of bladder, was felt a firm, smooth, hard, painless mass, encroaching upon the calibre of the gut, but not completely obstructing it. On passing the finger towards the left side this mass was found to be continuous with a similar mass filling up the left side of the pelvis, and apparently firmly attached to the left ischium. Behind the rectum the concavity of the sacrum could be felt apparently quite free. On passing to the right side of the central mass the pelvis was found to be occupied in the same manner as the left side, but to a less extent, and, upon pressing upwards with the finger here, tenderness was elicited. The rectum was found to contain liquid strong-smelling fæces, but no blood; one or two small solid portions of fæces were also felt; further, from the wall of the rectum small pedunculated soft masses about the size of small grapes could be felt; the interior of the bowel otherwise was quite smooth, the abdomen was slightly distended, and a hard, irregular, painless mass, dimpling on pressure and apparently fæcal, could be felt in the left iliac region; there was a little gurgling, too, on palpation.

May 22nd.—To have a grain of opium every six hours.

26th.—The patient having been prepared and anæsthetised, an incision about two inches and a half long was made halfway between the last rib and the crest of the ilium, the muscles and fasciæ cut through, and all bleeding arrested. Mr. Bryant then introduced his finger and felt the kidney with the bowel in front of it; this was difficult to bring to the front on account of the great number of adhesions; it was, however, inflated and brought out, when it was found to be of the normal thickness of wall. On this account, instead of being put through the bowel, the stitches were introduced, one towards the front through an appendix epiploica and three on the other side through a transverse band. The wound was then stitched up on each side of the bowel, a piece of which, to the extent of about an inch and a half, was left protruding. The wound was then dressed with oiled lint and padded up with iodoform gauze, and the patient put carefully to bed.

27th.—The patient feels very comfortable, only a slight tightness across the abdomen. Urine acid; sp. gr. 1025; no albumen. Morning temperature 102°.

28th.—Was sick last evening and in the night; he cannot keep down his iced milk; no pain in abdomen or wound. Morning temperature 100·4°. The opium pills were repeated. Sedative bismuth mixture ordered three times a day, and port wine, barley-water, milk, and lime-water allowed.

29th.—He was very sick early this morning, but this has ceased; he lies with his hands clasped over his head. Respiration chiefly thoracic; the abdomen, however, moves slightly. He complains of tenderness over the epigastrium, and a griping pain as soon as he takes anything to eat or drink. Around the wound there is a slight red blush; has suffered much from hiccough. Pulse 92, fair volume. Complains of a feeling as if the abdomen was being screwed up. He is now taking a little weak brandy-and-water.

30th.—Wound dressed to-day. There is a little discharge. The stitches were not taken out. Has had no hiccough last night or to-day. Respiration thoracic.

June 1st.—Bowel protruding nicely from wound; granulating healthily. One stitch was removed on each side, and the bowel opened with a small narrow scalpel. No anæsthetic was given, and the patient felt nothing of the operation. The handle of a scalpel was then introduced, and some portions of light-coloured fæces were removed.

6th.—Patient seems comfortable,; there is still a great deal of discharge.

19th.—Wound again dressed; there is still some discharge both from the anus and the colotomy opening.

July 28th.—Patient discharged.

In July, 1886, this patient was comfortable, and there was not much evidence of the local disease having progressed. The Sister of the ward has just heard of his death.

Syphilitic necrosis of tibia: fracture at this spot; sequestrotomy. (From notes by Messrs. Deane and D. J. Jones.)—A. B——, aged fifty-three, was admitted on Oct. 28th, 1885. Five years ago an ulcer appeared in the upper part of the sternum, which broke and then healed up; soon afterwards she had an ulcer on the left shoulder, which was soon cured; six months later she had a tumour on the dorsum of the tongue. The tumour disappeared, under treatment; but she continued to take the medicine for some months. About two years ago two ulcers came on the front of the leg, one above the other, midway between the knee and the ankle. She applied a lotion. In a short time the two ulcers joined, and they have been getting deeper since. Last week she got up from a chair to walk across the room; as she did so, she felt something in her leg crack, and was unable to walk a step.

On admission there was great enlargement of the left leg beneath an old ulcer; above and below the ulcer the skin was clearly defined, dipping down along the margin of the ulcer; there was a mass of black necrosed bone at the bottom of it. The bone was broken completely across at the seat of necrosis. There were scars of old ulcers on the sternum and left clavicle, and slight scarring on the soft palate and pillars of the fauces. Urine normal.

On Oct. 31st Mr. Bryant enlarged the wound, and, finding the sequestrum loose, he removed it in two pieces. The cavity left was found lined with granulation tissue, which was wiped away; the lower end of the upper fragment of broken tibia was also freshened by chiselling off a small portion. The antero-external surface was quite black from exposure, and hollowed out from gradual disintegration of its substance. Elsewhere the surface of the sequestrum was irregular and worm-eaten. There was very little production of new bone in the neighbourhood of the sequestrum. It was two inches and a quarter long, and the antero-external surface was one inch in breadth. The limb was put up in a posterior and two-side splint, as in a simple fracture.

Dec. 7th.—Wound dressed; two small pieces of bone (compact tissue) taken away.

15th.—Patient would not stay in the hospital, so the leg was put up in a plaster-of-Paris bandage, a window being cut in the bandage so that the wound might be dressed. There seemed to be firm bony union between the two ends, and the granulations were healthy-looking. At a later period the woman reported herself as well.

Sinus of right cheek following the impaction of slate pencil in antrum four years previously; removal of foreign body; cure. (From notes by Messrs. Price and J. Aynard.)—M. C——, aged sixteen, a pupil teacher, was admitted on July 16th, 1885. When quite young the patient had several blows about the cheek; to this her medical attendant attributes her present complaint. About three years ago patient's friends noticed that when she laughed there was a curious retraction of the skin about two inches below the right eye. On looking, they found a small hard lump about the size of a pea, which seemed to be attached to the bone, but evidently was also attached to the more superficial structures. On consulting a surgeon, she was told that if the first molar were removed she would probably get rid of her trouble. After the removal of the tooth cotton-wool was placed in the cavity; when this was taken out next day it was saturated with discharge; the discharge continued for a day or two. Seven weeks ago the patient was operated on. A small elliptical incision was made, and a lump about the size of a pea with the depressed skin was removed; the skin was then separated from the muscle beneath, and the edges of the wound stitched together. On admission she presented the same appearance as she did before the operation, the only difference being that the lump with the depressed skin around was smaller.

Under chloroform Mr. Bryant passed a probe through the small sinus, and felt what he thought was bone, then another probe was introduced and held in. The lip was now everted and pulled up by means of retractors; then the mucous membrane was divided, and some bone was removed with a chisel, and the superficial and deep structures were separated from the bone right up to the probe. Incisor forceps were now used to extract what turned out to be the top of a slate pencil; several other pieces were removed. A probe was next introduced where the pencil was taken from, and a communication with the orbital cavity was found. A plug of iodoform gauze was then introduced into the hole. On being asked about the pencil, the patient said that when quite young she fell down with a pencil in her hand, and it ran into her cheek.

On July 28th the patient left the hospital, the face being still swollen. Within two weeks, however, she was quite well.

MANCHESTER ROYAL INFIRMARY.

ACUTE TRAUMATIC SUPPURATIVE OSTEOMYELITIS OF THE HUMERUS; EARLY EMPLOYMENT OF THE TREPHINE; RECOVERY.

(Under the care of Mr. THOMAS JONES.)

FOR the following notes we are indebted to Messrs. Walker and Platt.

James C——, aged eleven, a half-timer in a foundry, was admitted into the infirmary on Nov. 20th, 1886. Father dead; cause of death unknown. Mother, one sister, and two brothers living and healthy. The patient himself bears no indications of any hereditary disease. On Nov. 11th he fell on his left shoulder. When he got up he was able to move his arm, and could put his hand on the top of his head. He had a good deal of pain at the time, and his arm has continued to pain him ever since. Next morning he went to his work, which consists in knocking off the rough pieces on iron castings with a hammer and chisel; and in the afternoon he went to school, but whilst there was sick, and had to go home. The pain was much worse that night, and three days later a medical man was called in, and on his advice a mustard plaster was applied to the shoulder, without any relief. The pain was of a shooting character, and began to increase in intensity about 6 P.M.

On admission the left shoulder was œdematous and very hot to the touch; there was a very tender spot on the inner side about the coracoid process, and here fluctuation was very distinct. The whole arm was swollen, tender, and red, and the subclavicular fossa effaced. Urine: sp. gr. 1020; alkaline; no albumen; no sugar; deposit of mucus.

On the 22nd the temperature of the right shoulder, taken by the surface thermometer, was 99°; of the left shoulder, 102·2°. The patient was put under chloroform, and an incision made on the front of the arm just below the junction of the upper epiphysis with the shaft. A considerable amount of pus was evacuated, and a piece of rough bone could be felt with the finger lying immediately to the outer side of the bicipital groove. A drainage-tube was inserted, and the wound dressed with iodoform and a wood-wool pad.

During the next three days the wound discharged very freely, but the temperature continued very irregular; so on Nov. 26th an exploration was conducted by Mr. Wright, who found the shaft of the humerus quite separated from its upper epiphysis. Some counter-openings were made, and the cavity syringed out with an antiseptic sublimate solution (1 in 3000) and drained. There was no improvement either in the local or general condition, the evening temperature reaching 102°, and even higher. On the 30th he complained of a very tender spot on the outer aspect of the arm, an inch and a half above the external condyle. There was very little spontaneous pain in the limb, but when handled intense agony was experienced. The lad at this time presented a dusky appearance, and had a short distressing cough and a most rebellious diarrhœa. He was again anæsthetised, and a vertical incision an inch and a half long made over the tender spot; the incision was carried down to the bone through infiltrated and œdematous structures, and the periosteum found to be thickened and easily stripped off, but there was no pus beneath it. The bone was then trephined, and about a teaspoonful of pus escaped, the suppurating medulla being at the same time exposed. The upper incision previously made was now enlarged downwards; the periosteum here was extensively separated from the bone, but there was no pus between the two. The trephine was again employed, and the medullary canal laid open. While this was being done, some thick pus oozed up into the wound. The medullary tissue between the two trephine holes was then removed, the canal washed out with the perchloride solution (1 in 4000), and a drainage-tube passed through it, its ends projecting from the upper and lower wounds. The same night he complained of intense pain in his arm, which was being irrigated with the sublimate solution (1 in 5000), but after a subcutaneous injection of a quarter of a grain of morphia he passed a very fair night.

The next morning the patient was much better; his temperature fell to normal, and the limb, although still swollen and œdematous, was free from pain unless handled. The piece of bone from the lower trephine hole was eroded and eaten away on its inner surface until the part was translucent. The pus was evidently making its way at this spot, which corresponded with an area of intense tenderness. After the trepanation and clearing out of the medullary canal the temperature gradually fell, and kept down for about a week, except on Dec. 3rd, when there was a slight rise owing to a block in the drainage-tube. On Dec. 8th, the temperature again began to rise, and the next day the patient was placed under the influence of chloroform, the drainage-tube removed, the medullary cavity syringed out, and a piece of solid rubber catheter placed in the lower sinus. The temperature continuing to rise on the 11th, the patient was again put under chloroform, and the upper end of the diaphysis was discovered to be quite loose, soft, inflamed, and infiltrated with pus. The epiphysis moved smoothly in the glenoid cavity, and the latter was apparently quite unaffected. The diaphysial extremity had been causing much annoyance and pain, so about an inch of it was removed. The wounds were dusted over with iodoform, and the sublimate irrigation continued. After this operation the temperature began to fall, and came down nearly to normal. The medullary canal was syringed out daily, and on the 21st the irrigation was discontinued, the wound being dusted over with iodoform and covered with a wood-wool pad. The medullary canal soon began to fill up with granulations, and by Jan. 15th, 1887, it became impossible to force any fluid through it. The temperature about this time on more than one occasion rose to 102°. There was nothing local to account for it, nor did the lad's general condition indicate anything going wrong, it having been steadily improving for at least ten days. His appetite was remarkably good, and, except when the arm was moved, he complained of no pain whatever. The piece of catheter in the lower opening was removed on Feb. 1st, and its removal did not occasion any rise of temperature. The discharge from this sinus steadily decreased. The granulations in the upper openings were exuberant and painful when the dressings were renewed. In the centre of the original opening there remained a distinct sinus, which led down to some dead bone. On Feb. 12th he was again anæsthetised, the sinus was enlarged, and a small sequestrum removed from the upper end of the diaphysis. The prominent painful granulations were scraped away at the same time, and the several surfaces dressed as before. After this, the patient's temperature remained normal, the arm was dressed every other day, the discharge visibly diminishing.

The patient left the infirmary on Feb. 26th, with two sinuses, the original opening and the trephine-hole still discharging a little. His condition at the present time is much the same, a small amount of pus escaping from the two sinuses. The arm is thicker than its fellow, from the large amount of new bone which has been formed by the periosteum; the shoulder and elbow joints are quite movable, and the boy has more than regained his original state of health.

Remarks by Mr. JONES.—It is not often that cases of osteomyelitis are seen in hospital practice at this early stage. The disease was no doubt induced by the injury, and commenced close to the upper epiphysial line of the humerus. It promptly produced a solution of continuity in this situation, and at the same time travelled downwards in the interior of the shaft. This mode of propagation is not so often observed as the upward, while we see it in the tibia when the acute affection commences in the upper end of the diaphysis of this bone. What guided me in the diagnosis of implication of the interior of the shaft was the non-appearance of improvement after the persistent abscess had been freely laid open; the lad maintained the same dusky aspect, and complained bitterly whenever the arm was touched. I was induced to perforate the humerus in the spot mentioned by the intensity of the pain produced by pressure being greater here than elsewhere; also in other and similar cases I have observed that Nature made an opening in this situation. Had we waited long enough, an exit for the suppurating marrow would have been established here as the condition of the circle of bone clearly proves. Meanwhile, however, the acute illness would have continued, and it is very doubtful whether the system would have been able to withstand the strain put upon it. What I did then was to anticipate and assist Nature in her efforts. It is a remarkable fact that the shoulder-joint remained intact throughout, although the disease was raging in its immediate vicinity. Indeed, we are told that a portion of the epiphysial junction is actually within the capsule of the scapulo-humeral articulation. This can scarcely have been the case in this instance.

Digitized by Google

otherwise the joint would not have remained so free from disease. It will be noticed that at the spot where the humerus was trephined there was no pus between the periosteum and bone, showing clearly that we ought not to wait for this before resorting to a perforation. To my mind, the clinical features of acute osteomyelitis are alone quite sufficient to warrant us in forming a diagnosis, and when once this is done, it is our duty, and without delay, to perforate the bone and drain the medullary canal after removing its contents. Nothing short of this treatment will suffice, and by adopting it early we should save the patient an immense amount of suffering, if not from actual death, besides diminishing the risks of a tedious necrosis. When the acute process subsides, a chronic change will generally go on for some considerable period, the bone becoming sclerosed and leaving unmistakable traces of the disease, which will have an important influence on its future life history. The case I have narrated is almost the exact counterpart of a historical case which occurred in the Manchester Infirmary nearly 120 years ago, and in which Charles White is supposed to have excised the shoulder-joint, but where in reality he removed the upper end of the diaphysis, which had become separated from the epiphysis, the patient recovering with a movable joint, and where the entire motion of the limb was preserved.[1]

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Congenital Dislocation of Hip. — Disease of Humerus (? Osteitis Deformans or Osteomalacia).—Fibrous Metaplasia of Bone.

AN ordinary meeting of this Society was held on Tuesday last, Dr. R. Douglas Powell, F.R.C.P., Vice-President, in the chair.

Mr. A. A. BOWLBY showed a specimen of Congenital Dislocation of the Hip, removed from a girl aged thirteen who died in St. Bartholomew's Hospital from a new growth in the stomach. She was the first child of the family. The labour was easy and natural, no interference being necessary. Nothing was noticed amiss till she began to walk, and lameness was but slight until about the age of three years. There was no history of accident, and none pointing to hip disease. An examination showed that the head of the right femur was displaced on to the dorsum ilii. In the position of the normal acetabulum was a triangular depression, which, although it evidently represented the acetabulum, was far too small to have accommodated the head of the bone at any time. The floor of the depression was covered on its upper part by cartilage, and its edges were scarcely raised above the level of the surrounding bone. The upper portion of the acetabulum, that formed by the ilium or the iliac segment, was deficient, and the cavity was formed by the junction of the pubic and sciatic portions. The head of the bone rested in a depression on the dorsum ilii immediately above the deformed acetabulum, and was in this situation surrounded by a fibrous capsule. The ligamentum teres was undeveloped. It is probable that this condition of the acetabulum is a more frequent cause of congenital dislocation of the hip than is generally allowed, and there are no good reasons for believing that such displacements are the result of injury during parturition.

Mr. LOCKWOOD showed two Fœtuses, both of which had Developmental Peculiarities of the Hip-joints. One was a stillborn microcephalic fœtus at about the full time; it was the sixth and last child. Its parents were very healthy. The midwife said that it was born a "double breech" presentation. The other five children are alive and healthy. The thoracic and abdominal viscera of the fœtus were normal. The skull was very bony and microcephalic, and the spine had a very well-marked lateral curvature. The brain only filled a small portion of the skull, and had no convolutions: it looked like a fibrous vascular bag. The cerebellum was exceedingly deficient and had the same appearance. The spinal cord was unusually thin, and reached as far as the lumbar region. The fingers were crumpled up into the palms of both hands, and the feet were in the position of talipes varus; moreover, the legs assumed a crossed position. The hip-joint possessed no rim, and was merely a shallow hollow. The head of the femur was not displaced. Mr. Lockwood thought that since the brain and spinal cord of this fœtus were so decidedly abnormal, and since the organs of volition were affected, and not the viscera, there was therefore some association between the two sets of conditions. The various histological specimens of the embryo showed that the margin of the acetabulum was formed in cartilage before the second month of intra-uterine life. This process seemed to have failed in this case. The second fœtus was born of healthy country parents. It was not the first child. It was delivered by Mr. Allen, who says that it was a breech presentation. After birth the legs had a curious tendency to remain flexed upon the abdomen. The fœtus had ectopia of the abdomen, with protrusion of the liver and intestines. In other respects the viscera of the chest and abdomen were quite natural. The brain and spinal cord were well grown and normal. The hands were flexed upon the arms to a right angle, and upon the right side there was no thumb, and upon the left a very rudimentary one. The head of the right radius was dislocated upon the front of the humerus. The margins of both acetabula were deficient, and the heads of the femora, instead of lying in their usual place, were displaced upon the dorsum of the ilium. Mr. Lockwood thought that in this case the absence of the margin of the acetabulum had predisposed to the dislocation, and the muscles had, during intra-uterine life, drawn the head of the femur upwards. The cases were compared with ordinary cases of congenital dislocation of the hip, and it was argued that the cases which went by that name were seldom, or perhaps never, traumatic, but due to developmental effects. He thought that in intra-uterine life physiological movements of the limbs were an essential element in the proper development of joints.

Mr. W. ADAMS exhibited two dried specimens from the museum of the College of Surgeons which belonged, in Professor Stewart's opinion, and in his own, to the class of Congenital Displacements of the Hip. Mr. Bowlby's case was, Mr. Adams said, of special importance, because it was accompanied by a trustworthy history, which was absent in all the other specimens in London, with one exception, which was that shown by Mr. Morgan. This specimen had been shown to the Westminster Medical Society by the late Mr. Edwin Canton (*London Medical Gazette*, N.S., 1848, vol. vi., p. 559) as an example of "congenital dislocation of both hip-joints." As the specimens exhibited proved, the head of the femur in these cases was displaced in various directions, directly upwards, upwards and forwards, upwards and backwards towards the sciatic notch, or on the centre of the dorsum ilii. All the specimens agreed in showing no trace of disease; but, on the other hand, the innominate bone was evidently congenitally deformed. The acetabulum was represented only by a flattened triangular depression, the base of which was formed by the border of the obturator foramen; while the apex corresponded to a point a little above that which should represent the centre of the acetabulum if that cavity were present. The upper half of the prominent border of the acetabulum, which should naturally be formed by the ilium, was entirely absent; so that there was nothing to prevent the head of the femur passing upwards on to the dorsum ilii when the weight of the body was thrown on the limb. In all these specimens the lower part of the innominate bone was narrowed and elongated; the ischial tuberosity was everted, and its ramus twisted; the head of the femur was smaller than natural, generally flattened behind and below, but covered with healthy articular cartilage; the round ligament was occasionally present, being greatly elongated; and the head of the femur remained within the capsule ligament, which was not only elongated, but thickened. The collection of specimens would help to dispel several errors; for it would be seen that the condition was really a consecutive displacement of the femur resulting from a congenital deficiency of the acetabulum, rather than a true dislocation. Two practical results were the outcome of these views. In the first place, the accoucheur must be freed from all possible blame in producing the displacement or so-called dislocation; and, secondly, the practice of dividing the tendons of the glutei and rotator muscles must be condemned as an irrational and useless procedure.

Mr. J. H. MORGAN exhibited a specimen from the Charing-cross Hospital museum, which was of historical as well as

[1] Particulars of this case were read before the Royal Society on Feb. 9th, 1769, and are recorded in C. White's "Cases in Surgery." London, 1770, p. 57.

Digitized by Google

pathological interest, as being the first specimen illustrating the condition of parts found in congenital dislocation of the hip. It was exhibited to the Westminster Medical Society in March, 1848, by Mr. Canton. The patient was a female, aged thirty-two, who was affected in both hips. She died fourteen days after giving birth to a living child at full term. Examination of one hip only was permitted. The body and upper limbs were well formed, whilst the lower extremities were somewhat atrophied. The head and neck of the femur were found on the dorsum ilii, the former having passed beneath the small external rotators, whilst a large bursa existed between the latter and the capsular ligament which immediately covered the former like a hood. This ligament preserved its natural connexions, but was considerably elongated, thickened, and strongly fortified with supplemental bands at its upper part. The head of the bone was coated by a bluish film of cartilage, which was continued over a superficial impression, marking the site of the pit for the ligamentum teres, which was not present. The portion of the dorsum ilii played upon by the femur was smoother than natural. The acetabulum was triangular in form, the base directed outwards; the height one inch, the breadth half an inch; the cavity was nearly filled with fat. Mr. Morgan remarked that although specimens exhibited that evening placed it beyond doubt that in some cases an erroneous development of the acetabulum occurred, and the head of the femur was thus forced to make for itself a socket upon the dorsum ilii, he believed that there were other cases in which inflammation of the synovial membrane occurring at or soon after birth, rupture of the ligamentum teres took place, and the femur was pushed out of the acetabulum, and drawn up on to the ilium. The appearances in the specimen which he exhibited were quite compatible with this view. He had had an opportunity of seeing this condition in a case under Dr. Barlow at the Hospital for Sick Children in Great Ormond-street, where the femur became dislocated in the course of rheumatic fever; and on cutting down upon it, the head of the femur was found thus displaced, covered by the stretched but unaltered capsule, and forming for itself a new cavity, in which it rotated. The acetabulum was filled to a level with its margin by granulation tissue. In two cases which had lately come under his observation, presenting all the clinical features of congenital dislocation, he had detected the marks of small abscesses, which very possibly had resulted from some such course of events.

Mr. SHATTOCK said that his specimen was precisely like that of Mr. Bowlby's. In Mr. Lockwood's specimens there was evidence of a strict intra-uterine malposition. He had dissected cases of what Volkmann called "genu recurvatum," in which the knee was over-extended. In a healthy individual either the hamstrings must rupture or a subluxation of the hip would occur if this faulty position were assumed.

Mr. D'ARCY POWER showed an ancient specimen, said to have belonged to Mr. Stanley, 1834, who had presented it to the museum of St. Bartholomew's Hospital.

Mr. HOWARD MARSH said it was still doubtful whether the dislocation of the hip might not be due to injury during labour. Mention was made of a case of back presentation, in which the dislocation might have been due to violence during delivery. He did not think that such violence was the usual cause of this "congenital dislocation." The condition doubtless varied slightly in different cases. As a rule, the joint appeared to be rudimentary, so far as it could be ascertained by external examination. Dupuytren had put hereditary cases on record. He mentioned a case in which the mother was similarly affected. This supported the view that an original defect must have been transmitted.

Dr. T. BARLOW supported the contention that some cases might be inflammatory in their origin. He referred to the case of a child one month old, in which there was a purulent swelling over the buttock, with considerable mobility of the hip-joint. Another abscess occurred in one of the joints of the foot, and the case was probably pyæmic. It had many of the characters of a congenital dislocation of the hip; the acetabulum was rudimentary, and oval in shape, and filled up by solid connective tissue; the head of the femur was swollen and spongy. The capsule was very large. The abscess communicated with the hip-joint. There was no sign of ulceration or caries, and Mr. Barker believed the abscess was secondary to the condition of the joint. A committee of the Pathological Society contended that it was a case of early arthritis which produced the condition of the acetabulum found. He rather supported this view. In early arthritis the ultimate changes were different from those found later in life. The power of formation of connective tissue was so great that union and healing might go on to a surprising extent, so that we might hardly suppose that an inflammation had ever been present. In cases of extensive bone lesions resulting from syphilis, the signs of actual inflammation might be very slight after the lapse of some time. We should not expect the final results of inflammatory disease in early life to show the same signs of destruction and caries as would be found in disease occurring in later life. In cases of dislocation occurring during fevers, without abscess, the anatomical appearances might be somewhat like those found in the congenital dislocation of the hip.

Mr. R. BARWELL considered that by far the greater number of congenital dislocations were due to malformation of the acetabulum, and a few to malformation of the head of the femur. He said that in some cases division of muscles could effect considerable improvements.

Mr. EDMUND OWEN had seen a case of breech presentation with congenital dislocation, in which neither the midwife nor the doctor had arrived before parturition. He did not think the condition of the hip-joint was a dislocation, but was due to the faulty position described by Mr. Shattock.

Mr. BOWLBY said that cases due to previous inflammation were separable from cases of so-called congenital dislocation.

Mr. J. R. LUNN showed a specimen of an obscure form of disease affecting the Humerus of a man aged eighty-six. Three months before his death it was noticed that the right arm was becoming curved outwards and was tender; no other bones were affected. There was no history of syphilis, gout, or rheumatism. The bone, when examined after death, was curved obtusely about the middle; the thickening was greatest where the bone was most curved, the bone regaining its normal dimensions at the ends. The bone was softened, the medullary canal at the curvature narrowed, and the cancellous tissue at this point tough and compact. The shaft above was rarefied, and the cancellous tissue within the tuberosity and neck deficient, the enlarged portion of the medullary canal being filled with fat. Mr. Shattock found that the curved portion of the bone showed, on microscopical section, well-formed osseous trabeculæ, including a vascular connective tissue; in parts, large osteoclasts lay against the trabeculæ, and there was abundant evidence that these had been altered in direction. In most of the spaces ossification was in active progress, and in places "brushes" of stiff osteogenic fibres spread into the new bone as "perforating fibres." New bone was also in process of formation in a dense, fibrous, connective tissue in the deeper layer of the periosteum. Mr. Lunn, after commenting on the difficulty of diagnosis and the improbability that it could be classed with osteitis deformans, owing to the fact that only one bone was implicated, expressed the opinion, founded on the microscopical appearance, that the case was an example of osteo-malacia affecting a single bone.

Mr. SHATTOCK read a note on Fibrous Metaplasia of Bone. He showed macroscopical and microscopical specimens of the femora of well-known cases of osteo-malacia: Howship's, from the Royal College of Surgeons; and Solly's, from St. Thomas's Hospital museum. Neither of these had been previously examined by the ordinary histological methods now in use. That the rarefaction was not due to osteitis was proved to the naked eye by there being no trace of osteo-plastic periostitis; and microscopically the evidence was still more weighty; for there was no hyperæmia, and any small-called infiltration was entirely absent. Moreover, in both cases the disease was progressing at the time of death, and caused death at the ages of thirty-five and thirty-nine. The specimens showed all stages of a direct conversion of the osseous substance into fibrous tissue. As Mr. Savory said, bone was but calcified fibrous tissue. In osteo-malacia the bone was unmade and reconverted into fibrous tissue. In Howship's case there was a distinct interval between these two processes. In the process there was sometimes to be seen the lacunæ enlarging and coalescing, as described by Durham in the Guy's Hospital Reports. The decalcified matrix, by its fibrillation, was converted into fibrous tissue. The connective tissue might become replaced by fat from infiltration of its corpuscles, and so there was, as Sir James Paget had described, a fatty degeneration. The term degeneration usually indicated that the tissue lost all its physiological functions. When one physiological tissue

Digitized by Google

results from another physiological tissue the process should be termed, after Virchow, "metaplasia," rather than degeneration. In museum preparations the spirit often had an acid reaction. In one case of spina bifida, amongst other acids, sarcolactic acid was found by Dr. Bernays, and probably resulted from muscular tissue. The presence of this acid might lead to a certain degree of decalcification, and prove a serious source of fallacy.

Dr. A. H. ROBINSON showed the Calvaria and one of the Clavicles from a case of Osteitis Deformans. A large sarcomatous tumour connected with the left lobe of the cerebellum, removed from the same case, was also shown. The patient was a clerk, aged fifty-two. He had never been intemperate, nor had he suffered from rheumatism or syphilis. There was no history of cancer in his family; his twin-brother died an imbecile. He was father of a family of ten children, his wife having had no miscarriages. Two of the children died of scarlatinal dropsy, at eight years of age, and were said to have very large heads, resembling in form their father's. One of the patient's brothers died at the same age, and suffered similarly, his limbs being much distorted. The patient's symptoms dated back ten years, beginning with pain in the back and weakness in the lower limbs. His left tibia was the first bone observed to be enlarged, and the head afterwards began to enlarge rapidly. The right femur and humerus then became thickened to almost double their normal diameter; for some months prior to his death, which occurred quite suddenly, he was bedridden. At the necropsy the left side of the heart was found to be hypertrophied, and the right dilated, the organ weighing fourteen ounces. There was no valvular lesion. The lateral ventricles were distended with serous fluid. To the left lobe of the cerebellum a large round-celled sarcoma was found adherent, probably springing from the membranes. There were no growths elsewhere in the body. The section of the skull showed hypertrophy, chiefly on the right side and in the occipital region, with complete obliteration of the sutures and disappearance of the diploë. A portion of the outer table was removed at the vertex, and showed a condition of rarefaction beneath. The thickening of the clavicle was confined to the inner two-thirds of the bone.—Mr. D'ARCY POWER said there was no thickening of the medullary canal, and considered that the specimen shown by Mr. Lunn was one of osteo-malacia, not osteitis deformans.—Mr. MACNAMARA said that there were different classes of osteo-malacia, as, e.g., those occurring in pregnancy and the specimens presented to the meeting. In some specimens there were evidences of distinct sarcomatous tissue which filled the medullary spaces. In cases of rheumatic arthritis the bony trabeculæ may simply have disappeared, owing to deficient activity of the osteoblasts, which allowed only of the formation of fibrous tissue. In osteo-malacia there was progressing softening, but in osteitis deformans a hardening and thickening process occurred also.—Mr. LUNN, in reply, agreed that there must be a softening stage as well as a thickening one.

The following card specimens were shown:—Mr. Lockwood: Development of the Hip. Mr. Adams, Mr. Morgan, and Mr. Shattock: Drawings of Congenital Dislocation of the Hip. Mr. E. H. Fenwick: Tumour of the Bladder. Dr. Willcocks: Congenital Malformation of the Heart. Mr. Shattock: Tubercular Disease of the Skin. Dr. Dakin: Atrophied Kidney and Dilated Ureter from a female child aged two. Dr. Colcott Fox: Infantile Scurvy.

MEDICAL SOCIETY OF LONDON.

Treatment of Hæmorrhage from the Tongue.—Catheter and Calculi removed by Lithotrity.—Renal Sarcoma in Infancy; is Surgery justifiable?

AN ordinary meeting of this Society was held on Monday ast, Dr. Hughlings Jackson, F.R.S., President, in the chair.

Mr. LOCKWOOD read a paper on a mode of restraining Hæmorrhage during Operations upon the Tongue. After speaking of the serious nature of that accident, the various plans which had been devised to prevent it were mentioned. None of these seemed to be quite free from objection, although all were more or less efficacious. After discussing the anatomy of the lingual artery, it was concluded that, at the place where the vessel lay upon the side of the pharynx near the greater cornu of the hyoid bone, the depth of tissues was so small that there could be no difficulty in compressing the vessel. The great constancy of the course of the vessel lent itself to this proposal. Forceps were then described which had been devised after a great many experiments upon the dead body. These instruments were quite efficient in preventing the passage of thin injection through the lingual artery. They were so arranged that one blade passed by the side of the tongue into the pharynx, whilst the other was bent to fit the contour of the lower jaw and meet the other near the tip of the greater cornu of the hyoid bone. Dissections had been made after the forceps had been adjusted which showed that the artery was tightly grasped and impermeable. A case was then described in which Mr. Lockwood had removed half the tongue whilst the forceps were in position. The tongue was split down the median septum and then removed with scissors. The lingual artery did not pulsate or bleed, and the operation was rapid and bloodless. Other cases were then described in which Mr. Willett had used the forceps; and, in conclusion, it was thought that there was a sufficient amount of evidence to show that the lingual artery might be easily and safely compressed.—Mr. F. BOWREMAN JESSETT thought that in limited disease of the tongue the forceps would be unnecessary, and when the glands were infiltrated the lingual artery should be ligatured as a preliminary. In such cases the instrument would be in the way.—Mr. MARMADUKE SHEILD said in rare cases of accidental wound of the posterior part of the tongue the instrument might be applicable.—Mr. SPENCER WATSON thought there would be no difficulty in applying the instrument to any jaw.—Mr. BOYCE BARROW thought ligature preferable to compression of the artery.—Mr. W. PYE referred to the feeble power of the forceps.—Mr. LOCKWOOD said that the ideal was to get cancer of the tongue so early that neither the whole of the tongue nor the submaxillary glands should require removal.

Mr. H. H. CLUTTON read a case of Catheter and Calculi removed by Lithotrity from a man aged twenty-nine, a groom by occupation, who was sent to Mr. Clutton by Mr. John Powell of Weybridge in September, 1886, on account of the following symptoms. Ten weeks previously a kick from a horse had ruptured his urethra. He was treated in a country hospital by a catheter tied into his bladder, and left in three weeks with the wound healed. He subsequently sent for Mr. Powell on account of the occasional passage of small calculi and inability to pass water. In using the catheter for his relief Mr. Powell found a calculus in his urethra and thought he felt another in his bladder. On admission into St. Thomas's Hospital he was found to have a fistula at the peno-scrotal angle, a stricture of his urethra, and a calculus in both places indicated by Mr. Powell. Under ether the stricture was dilated by Otis's urethrotome and a lithotrite introduced. During the manipulation small pieces of a black French catheter were found adhering to the jaws of the lithotrite, and eventually the fragments of a catheter, thirteen inches in length, were removed. The man lost all his bladder symptoms, and left the hospital perfectly well. He had, however, a small fragment in the urethra in a pouch behind the stricture, but he would not allow a second operation. Three months afterwards he reported himself as so well that he would scarcely permit an examination to be made. On further questioning after the operation, he gave the following history. One night in the country hospital, after a small catheter had been tied into his bladder, he was sitting on a bed pan and suddenly felt a sharp pain in his bladder as if he had been struck violently just above the pubes. He called the nurse and declared that the catheter had slipped into his bladder. She assured him this was impossible, and pointed to the bone end still adhering to the orifice of the urethra. The house-surgeon next morning, failing to find any evidence of the catheter, passed a larger one and tied it in. The mechanism by which a catheter may slip up into the bladder, or so far into the urethra as to be with difficulty withdrawn, was discussed.—Mr. E. H. FENWICK had had three cases recently in which the catheter was removed from the bladder by lithotrity. A case of a foreign body—an ear of wheat—was mentioned as having got into the bladder per urethram; it led to a calculus, which was removed supra-pubically.—Mr. W. PYE said that good rubber would be unacted upon by acid or alkaline urine.

Dr. ANGEL MONEY made a communication on the subject of Renal Sarcoma in Infancy, and specially discussed the question whether surgery was justifiable. He briefly related four cases that he had observed at the Hospital for Sick Children. All the cases had the characters of a renal

Digitized by Google

tumour, and in all the enlargement of the abdomen was the first clinical sign. Hæmaturia occurred in none. All the cases were females, and the ages ranged between eighteen months and thirty-four months. The other kidney was unaffected in each case. One tumour probably began in tissues not strictly renal. One was evidently of supra-renal origin, and in this case there was enlargement of the external genitals, on which an enormous growth of hair had taken place during the last nine months of the life of a female child aged twenty-one months at death. All the tumours were large, and abutted against the diaphragm. There were secondary deposits in three cases, and in the fourth the mesocolon was infiltrated as well as the retro-peritoneal glands. Dr. Money gave the statistics of Leibert from the *Jahrbuch für Kinderheilk.*, Band xxi., p. 276. Of fifty cases, both kidneys were affected only twice; twenty-six of the cases occurred under the age of three years. The course of the case was always longer as the age of the child was greater. A study of recorded cases in which nephrectomy had been performed seemed to show that life was not prolonged, even in the successful cases, and the statistics proved the dangers that attended the operation. So that, in his work on the "Treatment of Disease in Children," he summed up the present situation by saying that removal of the tumour is useless. Doubtless, if the tumour were detected when small, a chance for surgery existed, but, as a rule, the tumour was not discovered till it had reached a great size and secondary growths were almost inevitable.—Mr. MARMADUKE SHEILD thought they might be removed if small.—Mr. BERNARD PITTS said that the last case might have been suitable for operation. Cases seen early would be favourable for operation.—Dr. HUGHLINGS JACKSON asked what operation would be done.—Mr. F. B. JESSETT said the question of diagnosis was the difficulty.—Dr. ANGEL MONEY, in reply, said that so far operation had proved useless, but he hoped that surgery would show a better record in future, though this could only be by the physician's diagnosing the cases early.

HARVEIAN SOCIETY.

THE meeting on March 17th was occupied by the consideration of the subjects of Hereditary Syphilis and Habitual Constipation in Children.

Case of Hereditary Syphilis.—The PRESIDENT (Mr. Edmund Owen) showed a girl aged fifteen years, the subject of hereditary syphilis. She had first come under his care ten years ago, when she had an ulcerated gumma in the groin, and ulceration and sloughing of the soft palate and tonsils. She was then also the subject of symmetrical deafness of corneitis, and of inflammation of the upper epiphysis of each ulna and tibia. It was then ascertained that, when six months old, she had undergone a course of treatment by grey powders. Mr. Owen prescribed three-grain doses of iodide of potassium in plenty of water three times a day, under which treatment all the symptoms rapidly cleared up. A year later the child was again brought with an ulceration of the tonsil, which quickly yielded to the iodide; she had also periostitis of the shaft of the ulna, which ended in suppuration and in the exfoliation of a surface layer of the bone, which was shed in the quiet way so characteristic of syphilitic necrosis in childhood. After eight years' absence the child was again brought with chronic diffuse osteitis of each tibia, which had determined not only great thickening of the bone, but also a lengthening. This latter was to be explained by chronic inflammation in the cartilages connecting the shaft of the tibia with the epiphysis. There was also ulceration of the skin over the shins. The child was kept in bed, and every night was rubbed with blue ointment after having a hot bath; under this treatment she was rapidly improving. Mr. Owen also called attention to the scars at the angles of the mouth, to the large, square forehead, and to the teeth; the left central incisor was notched, and the central incisors were sloping towards each other.

Habitual Constipation in Children and the Methods of Treatment.—Dr. DAY read a paper on this subject. Most cases, he said, are due to (1) a sluggish state of the muscular coat of the intestine; (2) to a diminution of secretion from the mucous membrane or the liver; and (3) to improper dietary. Children are variously affected by constipation: the bilious and plethoric require a daily evacuation, or the health suffers; whilst the neurotic, eating similar food, may have no evacuation for days together without inconvenience. Prolonged constipation is apt to lead to disease of the cæcum, chronic inflammation and thickening of the intestinal walls, dilatation of the tube, and occasionally perforation of the gut. Highly nutritious food, by not furnishing any residuum to be carried into the intestines, is conducive to constipation. In treatment, the author referred to the importance of bringing about regular action of the bowels by the child making a voluntary effort every morning, whether the desire be present or not. He next referred to the value of enemata when the colon was torpid and the rectum blocked, and of proper diet in the constipation of young children. Among drugs, strychnia and belladonna, by imparting tone to the bowels, relieving spasm, and lessening flatulence, were advocated. Nitric acid in some cases of chronic constipation was recommended. The author dwelt at some length on the great efficacy of an occasional mercurial purgative in constipation from deficient secretion of bile. Children bear an occasional dose of mercury remarkably well, but if repeated too frequently it causes lassitude, pallor of the face, softness of muscle, and irritability of temper. He spoke of its danger in the constipation of strumous and rickety children. Saline aperients were sometimes useful in children of full habit. Change of air and exercise were recommended as calculated to assist the viscera in the performance of their functions. Massage he considered a powerful remedy in chronic constipation, and if conducted by a competent person the process was pleasant and soothing to the child. Attention to diet was of primary importance.—The PRESIDENT called attention to the importance of making a digital examination in all cases of chronic constipation, and quoted a case where such an investigation led to the discovery of congenital deformity of the bowel.—Mr. CRIPPS LAWRENCE remarked on the treatment of typhlitis due to chronic constipation.—Dr. JELLY referred to the value of massage as a therapeutic agent.—Dr. ALDERSON remarked on the value of mercurial treatment in the case of bilious children.—Dr. WALTER PEARCE considered that constipation in some cases depended on the child avoiding stool, owing to the pain produced by soreness of the anus consequent on the irritation of thread worms.—Dr. SYDNEY PHILLIPS agreed that aperients should not be lightly used; tubercular peritonitis, obstruction from concretion, &c., had to be carefully considered. In many cases there was a deficient formation of bile; the stools were pale, hard, and scybalous in these children, and the administration of acids and calomel was called for. In many cases the small intestine was at fault and not the large, and it was necessary to decide if possible where the fault lay. The combination of aloes and belladonna was most valuable.—Dr. DAY briefly replied.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Coal Gas as a Cause of Sore-throat.

AT the meeting on April 15th, Dr. Alfred Hill, president, and subsequently Dr. Dudfield, vice-president, in the chair,

Professor CORFIELD read a paper on Outbreaks of Sore-throats caused by slight escapes of Coal Gas, of which the following is an abstract. He pointed out that in considering the deleterious effects of escapes of coal gas into dwelling rooms, attention has hitherto been almost entirely directed to cases of poisoning by asphyxia produced by such escapes—asphyxia which has been shown to be due to the carbonic oxide contained in the coal gas. He referred at some length to the interesting recent investigations of Professors W. T. Sedgwick and W. Ripley Nichols, of the Massachusetts Institute of Technology in connexion with the relative poisonous effects of coal and water gas, but these investigators only refer to effects produced by the carbonic oxide, and indeed conclude that "it is probably true that carbonic oxide is the only component of illuminating gas whose poisonous qualities are at present of practical importance to the public health." Michel Lévy, in his treatise on Hygiene, suggests that some of the effects produced on persons working in atmospheres charged with the products of combustion of coal gas may be due to unconsumed substances, such as the sulphite of carbon, but the author has been unable to find any account of definite illnesses produced by continuous slight escapes of coal gas from defective burners or joints in pipes. Dr.

Digitized by Google

Corfield then stated that during the past few years his attention has been gradually arrested by cases of illness, and more especially of relaxed, and even of ulcerated, sore-throats occurring in persons sleeping in rooms in which there were defective gas burners or pipes, but living in houses of which the sanitary condition was otherwise as perfect as the application of modern sanitary knowledge could make it. That the slight escapes of gas were the cause of the sore-throats was proved by the fact that the persons attacked became quite well on the defects in the gas burners or pipes being remedied, and that no other cases occurred. The following are some of the more remarkable cases which he described. In 1884 Dr. Corfield was summoned to a large country house, where the sanitary arrangements had been put into order under his own direction. On inspection, no escape whatever was found either from the drains or soil-pipes into the house. A slight escape of gas was noticed from a burner in the bedroom, in which the first case of sore-throat occurred, but this was not at the time thought to have anything to do with the matter, more especially as a nuisance had been created in the neighbourhood of that room by an earth-closet which the men-servants had brought in from outside and had used without properly supplying it with earth. However, after the removal of this nuisance, several more cases of severe ulcerated sore-throat occurred, some being those of visitors who successively slept in a particular room. On investigating the matter further, the author, who himself slept a night in that room, found a very evident escape of gas from one of the brackets there, the gas having, moreover, a very foul smell from being insufficiently purified. An examination was then made of the gas brackets all over the house, and other escapes were found. These were all remedied, and no cases of sore-throat have occurred since. At another house in London a similar outbreak of sore-throats took place on the return of the family after the summer outing. Slight escapes of coal gas were found in the rooms in which the persons who were attacked slept. These were remedied, and there have been no more cases of sore-throat. Several other similar cases were described by Dr. Corfield, who ended by saying that he himself had personally suffered in a similar manner from a slight escape of gas from a defective pipe in his own bedroom. He also pointed out that coal gas may get into houses through the basement, floor, and even up through the walls, especially behind panelling from defective mains in the streets. He had no doubt that the cause of the sore-throats was the breathing for weeks or months, especially at night, of air contaminated with a small proportion of coal gas, and he believed that the effective agents in producing the irritation in the throat were the bisulphide of carbon and other sulphur compounds in the gas.—In the discussion which followed, Dr. Sykes, Messrs. Wynter Blyth, Rogers Field, Butterfield, and Shirley Murphy took part.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on March 4th the following communications were made.

Intussusception of the Bowel: Abdominal Section: Recovery.—Mr. STREET read the case of a boy aged three years, admitted into Addenbrooke's Hospital, under Mr. Carver, on Jan. 20th, 1887. There had been pain, vomiting, and partial obstruction for four weeks, and complete obstruction for three weeks. The abdomen was opened on the day of admission, and the intussusception reduced. The patient was discharged cured, the bowels acting regularly, on March 5th.—Mr. ARNOLD INGLE (Shelford) mentioned the case of an infant five months old, who was attacked one day with pain in the body, and vomiting the next day. When seen by him on the third day there was no abdominal swelling or tumour to be felt, but two motions had been passed of bloody mucus. An aperient was given and the bowels acted, but the vomiting recurred; the abdomen became distended and the child died. At the necropsy a diverticulum was found in the ileum, and an intussusception of the bowel.

Cyst of Cerebellum, enclosed in Fourth Ventricle.—Mr. HEMMING (Kimbolton) described the case of H. N——, aged eighteen, who till twelve years of age was healthy and bright; then was attacked with unilateral convulsions, with aura up the left side; slight paresis of the left side generally followed each fit for a short period; the fits increased in frequency, the mind gradually weakened, and the body ceased to grow. He walked about for two years, then kept his bed for the last four years, gradually losing consciousness. He had not spoken for a year and nine months, and there was extreme rigidity of the left side for more than a year. The convulsions at last were bilateral, and the rigidity extended to the right side, neck, and back. Great emaciation took place, and he died of sheer exhaustion, the convulsions persisting to the last. At the necropsy the skull was thick, well ossified; head small, no gaping of sutures; dura mater not very adherent, not dry or sticky; some fluid between arachnoid and dura; brain rather shrunken; no apparent disease in motor area of cortex; arachnoid of Sylvian fissure glued up; cranial nerves looking healthy, except that the optic appeared small and very firm (his parents considered he had had no sight for some time); veins thickened; sinuses not gorged; corpus callosum firm and healthy; lateral ventricles containing fluid, but not much distended; third ventricle opened up by fluid, and anterior commissure tough; commissura mollis very tough, stretching half an inch without tearing. The fourth ventricle was distended into a globular form, lifting up the cerebellum, with thin and transparent walls posteriorly. Fluid clear, and floor of fourth ventricle perceptible through the fluid. Although fluid had drained from the lateral and third ventricles, the fourth ventricle remained distended. Cerebellum firm, not to say hard. On opening the fourth ventricle, a small cyst, containing clear yellow fluid, of the size and shape of a hazel-nut, presented itself on the right side of the under surface of the cerebellum. It was partially embedded in the substance of the right lobe of the cerebellum, causing a sharply defined concave indentation and some extra hardening and thinning of the lobe around it. Mr. Hemming, on examining the pons and medulla, did not at first recognise any evidence of pressure, but these parts were removed and sent to Dr. Sharkey, who instantly noticed the small size of the right pyramid in the medulla before decussation, a drawing of which was shown. No doubt the pressure of the cerebellum in the living state upon the back of the pons and medulla was the cause of the gradual and prostrated illness, of convulsions, paralysis, and rigidity, and this case would support Dr. Sharkey's view.

Cases of Cerebellar Tumour.—Mr. MARTEN brought forward the case of M. S——, aged fifty-two, admitted into the hospital, under Dr. Bradbury, on Dec. 1st, 1886, and died on Jan. 8th, 1887. The symptoms had been severe occipital headache, vomiting, double optic neuritis, and a tendency to fall backwards in the middle line. No rigidity. The post-mortem examination, made by Mr. Griffiths, showed a cyst in the cerebellum pressing on the fourth ventricle, and excess of fluid in the ventricles.—Mr. LAURENCE HUMPHRY read the case of Ellen W——, aged twenty-one, single, admitted into the hospital, under his care, on July 14th, and died on October 25th, 1886. The previous history showed twelve months' frontal and parietal headache, dizziness, and vomiting. The eyesight became defective in March, and complete blindness in June. No fits or rigidity. On admission she was just able to walk. Pupils dilated, no reaction to light, no squint; constant purposeless vomiting; pulse regular, 64; temperature normal; speech laboured and thick. There was slight paresis of the muscles on the right side of the mouth and right supra-orbital region. The grasp of the right hand was a little weaker than the left. Reflexes were normal. There was no tenderness to percussion over head. Flushing of face was constantly noticed, and there was intense double optic neuritis. The urine contained no albumen or sugar. The patient left the hospital, but was kept under observation, and gradually sank from exhaustion. At the necropsy a tumour (a round-celled sarcoma) was found on the upper aspect of the cerebellum, of the size of a tangerine orange, and there was much basic meningitis and gelatinous thickening of the membranes at the base, involving the optic commissure and nerves.

Sarcoma of Testis in a Child.—Mr. STREET showed this tumour, which had been removed by Mr. Wallis from a child four years old. The swelling was first observed nine months ago, and at the time of operation was as large as a duck's egg. It extended up to the internal abdominal ring. The child recovered. Microscopic examination showed a spindle-celled sarcoma, with a large amount of fibrous tissue.

MIDLAND MEDICAL SOCIETY.

A MEETING was held on March 16th, Mr. Lloyd Owen, F.R.C.S.I., President, in the chair.

Chronic Phlegmasia Dolens, leading to Elephantiasis.—Dr. SUCKLING showed a man, aged thirty-eight, who had suffered from enlargement of the left leg for nearly four years. The swelling commenced in the foot, and shortly after an abscess formed in the groin, which discharged externally, leaving a depressed scar. The leg has remained enlarged since then, and is now much larger than its fellow; the skin is rough and thickened, and can scarcely be pinched up. There is well-marked pitting upon pressure in the foot and leg. The circumference of the left thigh is three inches greater than that of the right, and the left leg is similarly enlarged. The patella and tibia on the left side are apparently much enlarged. A depressed scar is present in the groin, and enlarged glands can be felt there. The patient cannot walk about for more than a month at a time, the leg then becoming very painful and the swelling increasing. At this time he has to go to bed for a week or so, when the pain ceases and the swelling somewhat subsides.

Gastric Ulcer.—Mr. WHITTINDALE showed the stomach from a female aged twenty-two, who had died in the Queen's Hospital. For the last four months she had had pain in the epigastrium and vomiting after taking food, but no hæmatemesis. Two hours before admission there had been profuse hæmatemesis. This stopped for a time, but was soon followed by another attack, which proved fatal. On a post-mortem examination all the organs were found to be exceedingly anæmic. The stomach contained a pint of dark grumous material and blood. On the posterior aspect, near the lesser curvature and at the pyloric end, there was a chronic ulcer the size of a sixpence, the edges of which were much indurated. A large vessel had been opened by the ulceration, but the serous coat was not perforated.

Renal Calculus.—Mr. MORRISON showed a uric acid calculus that had been removed from a man who had been treated for spinal disease for many years. On admission to the General Hospital he had several sinuses in the left lumbar region, which led down to a roughened body, supposed to be a sequestrum. This, on removal, was found to be a calculus. The patient made a perfect recovery.

Pyo-salpinx.—Dr. MALINS showed a large pyo-salpinx that he had successfully removed from a patient aged twenty-eight.

Rhinolith.—Mr. AUGUSTUS CLAY showed a large rhinolith.

Mr. SIDNEY BARWISE read notes of a case of Mollities Ossium.

Dr. CARTER read two short papers: one, "Observations on the Salicyl Treatment of Acute Rheumatism"; the other, "A Note on the action of the Colchicum Preparations in Gout."

At the meeting on March 30th the following specimens were exhibited:—

Syphilitic Stenosis of Trachea.—Dr. SUCKLING showed a woman aged fifty with signs of tracheal stenosis, which he considered was most likely due to syphilis. She contracted syphilis twenty years ago, and five years later she suffered from ulceration of the hard palate, which resulted in perforation. For the last nine years she has suffered from difficulty in breathing, which is noisy and stridulous. The stridor is constant, accompanying both inspiration and expiration, but is aggravated by emotion and by exposure to cold. On several occasions the dyspnœa has been extreme, and almost necessitated tracheotomy. The breath sounds over the larynx and trachea are high pitched and sibilant. The hard palate is perforated in the middle line and on the left side. There is no laryngeal stenosis or other disorder, the cords moving freely. On inspiration the glottis is rhomboidal in shape, being extremely dilated. Nothing abnormal could be seen in the trachea. There were no signs of mediastinal tumour, no dysphagia, or other pressure symptoms.

Aneurysm of Aorta.—Dr. SUCKLING also showed a case of aneurysm of the transverse and descending aorta in a man aged sixty-three.

Epithelioma of Male Breast.—Mr. BARLING showed a patient aged forty-seven, who nearly five years ago noticed a burning and smarting pain at the left nipple, and on handling the part found a hard swelling; this slowly increased, and eighteen months ago the skin over it broke. Since that time the ulcer has slowly increased, until now it is a circle of three inches in diameter, shelving gradually from the edge to the centre, which is the deepest part. For the most part the ulcerated surface is nearly smooth, but presents in places a few coarse granulations. The edge is thickened, very hard, and markedly everted, and the base of the ulcer so fixed that it cannot be moved over the bony wall of the thorax. There is a chain of enlarged glands running to the top of the axilla under the anterior boundary, and some hard enlarged glands are also to be felt above the clavicle. The patient's general condition is good, and, as a rule, he has but little pain. A scraping from the ulcer shows that it is a squamous-celled carcinoma.

Multiple Exostoses.—Dr. W. RICHARDS exhibited a case of multiple exostoses.

Excision of Goitre.—Mr. CHAVASSE showed a woman aged twenty-nine, from whom he had successfully removed the right lobe of the thyroid, and read a paper on the subject.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Treatment of Lupus.—Removal of Uterine Appendages.—Athetosis.

A MEETING of this Society was held on Jan. 21st, Mr. Hatherly, President, in the chair.

Mr. CHICKEN read a paper on the Treatment of Lupus and its Allied Disorders. He took epithelioma as a type of the diseases allied to lupus as exhibiting a cutaneous or mucous cell development, infiltrating or penetrating subjacent tissues, and depending on a specific morbid impulse. In the case of an affection of the skin, or those parts which could be safely operated upon, he advocated the treatment of the part by thoroughly scraping away, as far as possible, the new growths, and then the free rubbing in of iodoform. In those instances where the situation was such that this could not be done—as, for example, in epithelioma of the cervix uteri—he employed the frequent application of iodoform. Although, in these difficult cases, it was not possible to eradicate the disease, it modified the subsequent progress and unpleasantness of the malady in a marked degree. In epithelial stricture of the rectum, he first washed out the bowel with warm water, and then injected into the stricture from two to four drachms of iodoform daily by means of a special insufflator. In exposed situations, where the treatment could be thoroughly carried out, the result was very satisfactory. He showed two cases, one of lupus and one of epithelioma, both of which had been operated upon in the manner described, some years ago. There had been no recurrence. Mr. Chicken drew the following conclusions:—1. That lupus and epitheliomata are types of a cellular infiltrating new growth, and are best treated by scraping with a blunt knife, and when the surface has been as far as possible cleared from the invading cells, by rubbing in a remedy, of which iodoform is a good example, with the object of penetrating to those outlying detachments which the knife has not reached. 2. That when the growth is situated in a part that can be readily attacked the treatment gives ground for a good hope of recovery, at any rate better than excision. 3. That when the situation is such that scraping cannot easily be done, the copious insufflation of large quantities of iodoform is practically without risk and of great benefit to the condition of the patient. 4. Iodoform is specially applicable, because it seems to exert a specially sterilising influence on the growth, and is capable (by virtue of its volatile and peculiar penetrating properties) of permeating tissue more than an insoluble non-volatile substance. It is quite harmless and unirritating to healthy structures.

Dr. MUTCH showed the Ovarian and Fallopian Tubes removed by Dr. Elder from a patient aged twenty-seven, married. The left tube, about the size of a kidney, was full of pus, the ovary being converted into a multilocular suppurating cyst. The right tube was enlarged and inflamed. The patient made a good recovery.

Dr. ELDER showed the following specimens:—1. Sac of an Ovarian Cystoma, of which the pedicle had become

Digitized by Google

twisted, producing suppuration of its contents and acute peritonitis. 2. The ovaries and Fallopian tubes from a patient operated upon on Jan. 13th. The patient has been more or less of an invalid since marriage; lately quite so. The uterus was retroverted, and the ovaries, enlarged and exquisitely tender, lay under it in Douglas's pouch. Rest and the usual treatment had failed to give even partial relief. At the operation both uterine appendages were removed, the ovaries being enlarged and the seat of cystic degeneration. She is making an excellent recovery. 3. Uterine appendages removed by his colleague, Dr. Truman, for persistent pain, dating from one month after the patient's marriage three years ago.

Mr. T. D. PRYCE showed a case of Athetosis in a youth aged seventeen. There was a history of convulsions when eleven months old, followed by loss of power and motion of the right side. Mr. Pryce considered the condition to be due to a cerebral lesion coincident with the early convulsions, and also to a subsequent degenerative change of the lateral columns, and to a slight extent of the anterior grey matter of the spinal cord.

At a meeting held on April 1st,

The PRESIDENT (Mr. Hatherley) showed for Mr. Thompson a specimen of Enchondroma of Finger.

Drs. HANDFORD and HUNTER showed a case of Congenital Absence of Left Leg, Left Pelvis, and Left Kidney. The diaphragm and lower part of rectum were also absent.

Dr. ELDER read notes on two cases of Hydramnios.

Mr. PRYCE read a paper on Perforating Ulcer of the Foot, and illustrated it by pathological and microscopic specimens and diagrams.

Reviews and Notices of Books.

On Fevers: their History, Etiology, Diagnosis, Prognosis, and Treatment. By ALEXANDER COLLIE, M.D. London: H. K. Lewis. 1887.

THIS volume, which forms one of the "practical series" of medical and surgical manuals in course of publication by Mr. Lewis, deserves attention from the fact of its author having been so long devoted to the subjects of which it treats. He is therefore in a position to speak with authority, as well as with complete freedom and independence. Illustrations of these characteristics are not far to seek. They are perhaps most particularly to be found in the chapters dealing with enteric fever and small-pox. On the etiology of the former disease Dr. Collie has no hesitation in adopting views which at the present day are held by comparatively few. They are the views of Budd rather than those of Murchison, and are supported by the author with some striking evidence of the propagation of the disease amongst the nurses at Homerton Free Hospital. Dr. Collie has been persuaded by this experience to the belief that enteric fever is propagated by direct infection; and he explains the apparent facts of incommunicability on the grounds of immunity and the early period of life at which it prevails. Upon this we need only remark that the *onus probandi* rests upon those who adopt Dr. Collie's argument, since the possibility of contagion through fæcal contamination must be quite excluded before such a conclusion can be reached. Amongst other statements which are undoubtedly novel we note those with regard to relapse in enteric fever: "Relapse occurs in a small proportion of cases..... It is rarely fatal. Second and third relapses have been mentioned, but they are very rare" (p. 78). "*Relapses:* These are almost invariably mild and the prognosis favourable" (p. 84). The rarity of relapse here implied does not accord with our experience; and the posthumous work of the late Pearson Irvine clearly proved how many cases of prolonged typhoid must be regarded as examples of relapse. Dr. Collie has never met with enteric fever in the subject of phthisis—a suggestive and striking fact, which, like many other statements, is of much value in the natural history of the disease. Within a small compass he has succeeded in giving a clear outline of the main facts, but has not discussed the question of etiology which has come so much into prominence of late—we mean that of the typhoid bacillus. The article on small-pox, again, bears evidence of the author's personal observation, and is illustrated by tables showing the influence of vaccination upon mortality. The strongest parts of the work are those which deal with diagnosis and treatment, for here Dr. Collie is thoroughly at home and succeeds in imparting to the work its "practical" character, for which it will be highly valued. Nevertheless, we are not wholly satisfied with it. The author has not, it seems to us, given himself scope enough to adequately discuss his subjects. He relies too often, in the descriptive passages, upon excerpts from other writers, whereas we well know how capable he is himself of clinical description. The book is well printed, and contains some coloured plates illustrative of typhoid and variolous lesions.

Sputum; its Microscopy, and Diagnostic and Prognostic Signification. By FRANCIS TROUP, M.D. Edinburgh: Oliver and Boyd. 1886.

THE thoroughness with which it is possible to investigate clinically cases of pulmonary disease is one of the most encouraging facts in scientific medicine. The microscope comes to the aid of the stethoscope, and the information gathered by the one serves to justify or modify that derived from the use of the other of these essential instruments. Dr. Troup deserves well for having presented in so lucid and striking a manner the results of his own researches into the microscopical characters of the sputum. Availing himself of photo-micrography, he has so amply illustrated his work that a study of the plates alone will be of the greatest possible service. We have seldom seen such excellent photogravures and chromolithographs; and their fidelity to the objects represented is, at least in the case of the former, of course unimpeachable. The text is also to be commended, for it is evident that the writer speaks from the fulness of his own personal knowledge. It is, for instance, an instructive point to bear in mind that he has found the detection of elastic tissue in the sputum to have a greater diagnostic meaning in tubercular phthisis than the presence of the bacillus; for 90 per cent. of the cases in which elastic tissue is found are cases of tubercular phthisis, from which it is not difficult to distinguish other destructive lung diseases that yield the remainder. Dr. Troup also lays great stress upon the relative abundance of the pulmonary elastic tissue as indicative of active destruction. There is an interesting chapter upon Curschmann's spirals, which are to be found in cases of bronchial irritation, and are probably formed primarily in the minute bronchioles. The bacillus of tubercle is treated with all necessary detail; and its persistence in putrefied sputum leads to a remark condemnatory of the bacterium termo treatment. Dr. Troup also notifies the occurrence, not only in phthisical sputum, but in all cases where there is more or less bronchial inflammation, of diplococci of various sizes and arrangements, sometimes in large numbers. He considers that the tubercle bacillus is of more value in diagnosis than in prognosis. A chapter on pneumonic sputa follows, and the opinion held that various forms of pneumonia are probably associated with other micro-organisms besides the pneumococcus. In the next chapter the characters of the sputum in bronchitis, bronchiectasis, and whooping-cough are considered. Micrococci are described in the latter, but are not believed to be pathognomonic. Other chapters deal with pigmented sputa, bloody sputa, and the sputa in disease of the larynx and its neighbourhood. The volume is one which, apart from its practical value, has been produced in a manner highly creditable to both author and publishers. We heartily commend it to the notice of practitioners.

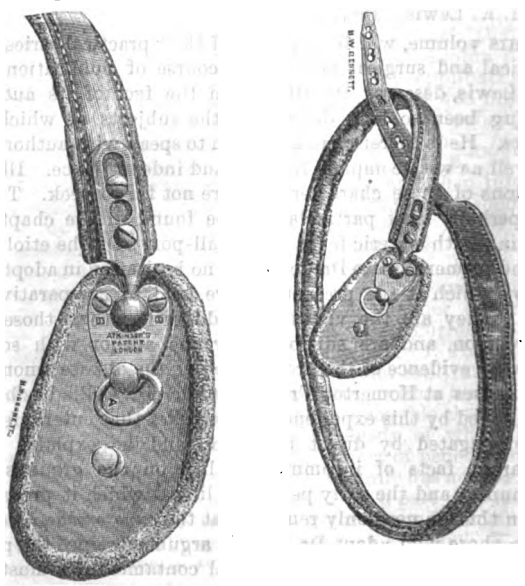
The Man of Science, the Man of God—Sir James Y. Simpson. By the Rev. CHAS. BULLOCK, B.D. London: *Home Words* Publishing Office, Paternoster-square.

THE scientific reputation of Sir James Simpson is world-wide. The double presentation of his mind and character which is set before us in this modest volume and in the larger "Life" is perhaps less widely familiar. In these pages, while personal faults are not denied, the rise and growth of qualities which proved in their application so useful to mankind are clearly brought out. Professor Simpson, it may be noticed, was not, like some great men, a human phenomenon from his earliest youth. As a boy he evinced, nevertheless, the elements of mental and moral faculties which needed but the stimulation of circumstances, not always favourable, to develop a strong and helpful as well as a keenly perceptive character. He was quick, industrious, tenacious of memory, and generally liked because of his kindness of disposition. As a student he was of the working order, and achieved considerable distinction in a time when the Edinburgh school did not abound in scholastic honours. When, after graduation, he became a practitioner, the same laboriousness was one of his most striking characteristics. Energetic and resolute, sleeping often far too little, persevering in spite of occasional ill-health, he did full justice to scientific sympathies which were wide and yet particular. He was no mere specialist, though leaning from the first towards one department of medicine. Matters of the most general, even comparatively trivial, interest engaged his attention for the time being almost as if they formed the chief business of his life. Investigations in anæsthesia very early entered into his varied curriculum of self-education, and when at last, in 1847, he saw the dawn of his own great discovery in the successful use of ether for this purpose, he "could think of naught else." As a man Professor Simpson did not belie the promise of boyhood, but, notwithstanding the faults of an impulsive nature, exaggerated by the bustle and battle of life, gave in his day many proofs of a genial and considerate disposition to friends and patients of every station. Neglect of professional engagements has been attributed to him by some, but this was commonly the natural consequence of overwork. Till he had reached the prime of manhood Professor Simpson's most active life was almost entirely an intellectual one. Religion did not show itself much upon the surface. Certain forms he acknowledged; he chose his church, but it is not till within some twelve or thirteen years of his death that we find any important profession of his personal views upon the subject. It does not appear, however, that his ultimate adhesion to the simplest principles of evangelical belief was quite a sudden matter; it was rather the culmination of previous deliberations, and was characteristically outspoken. The reading public will find much to interest in this little work. One or two errata might be excluded from later editions, such as "Wallis" for "Walter" on p. 48, and "Turner," we suppose for "Thomas" Keith on p. 55.



On Medical Climatology: a Scheme for defining Local Climates by combined Meteorological and Phenological Observation. By CHARLES ROBERTS, F.R.C.S., &c.

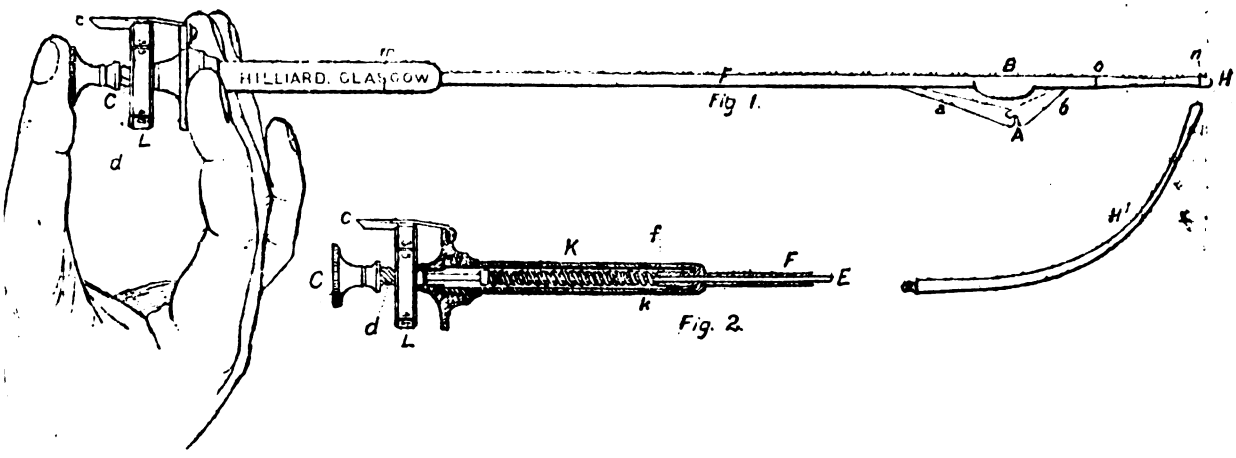
THIS is a short paper read by Dr. Roberts at the congress of the Sanitary Institute held at York last September. The title explains the proposed method of the author. Linnæus long ago collected information with the view of showing the influence of locality upon the leafing, blossoming, fruiting, and fall of the leaf in plant life. We are accustomed to estimate the climate of any given locality by purely meteorological considerations. Mr. Roberts holds, and we think with good reason, that a combination of these two methods might lead to results of great practical utility. He points out that "plants are most exposed to, and most distinctly declare, the geological and climatic conditions of a country or district. Being fixed to the soil, they show its character; and being confined to one place, they sum up the whole range of meteorological phenomena to which they are, and have been, exposed." The researches of Bowditch in America and of Buchanan in this country have shown how important a factor the character of the soil is with regard to the etiology of one important disease—viz., phthisis. Mr. Roberts proceeds to tabulate the dates of the various epochs of plant development in different localities, and then works out the temperature and moisture equivalents for these periods. On page 5 he gives an interesting diagram, showing at a glance the relative viability of a few common trees, shrubs, and flowers in London and its neighbourhood. Mr. Roberts' methods of observation are full of interest to the botanist, and have promise of real utility for the medical climatologist and the practical physician.

New Inventions.

ATKINSON'S "PERFECT" TRUSS.

MR. B. J. ATKINSON, formerly of 3, Hemming's-row, Charing-cross, but now of 7, Mill-street, Hanover-square, W., has recently patented an important improvement in trusses. This consists in uniting the pad to the spring of the truss by a universal joint, thereby allowing it, when necessary for adjustment, to be moved in any direction. When the wished-for position has been attained, a lever, acted upon by a binding screw, compresses the ball of the joint and completely fixes the pad. The accompanying woodcuts will afford a good idea of its construction. When an alteration

in the position of the pad is required, the binding screw is released, the pad adjusted, and the screw again tightened. A special feature, also, of this truss is that it is made to press over the internal ring, and slightly in advance, without pressing upon the spermatic cord; and further, from the peculiar formation of the pad (a perpendicular section of which will show a parabolic curve) pressure may be made by a comparatively flat surface or a more or less obtuse one, at the discretion of the surgeon. The whole design has been very carefully considered, and can best be understood by an examination of its parts. The form of truss varies, of course, in the case of femoral hernia, though the above remarks apply as well to this condition. The practical surgeon will see the great advantages presented by this kind of truss.



Digitized by Google

A MODIFIED FORM OF URETHROTOME.

A LARGE majority of surgeons are agreed that internal division is the best treatment of many strictures of the urethra. Of the innumerable instruments for the performance of this operation which I have seen or have been able to find described, all of them, while possessing many good and ingenious qualities, have had also some one or more faulty features. My aim has been to combine in one instrument all the good and eliminate all the bad points. I do not claim for my instrument many original features, only that it possesses the merits and avoids the faults of its predecessors.

That this instrument possesses the other qualities of a perfect urethrotome as given above will be seen from the following description. It consists essentially of a jointed knife (A, fig. 1), which can be projected from a sheath (B) to regulated distances. This is effected by pressure on the button (C, figs. 1 and 2), which is continuous with the steel rod (E, fig. 2) tightly fitting the tube (F), the end of this rod being the knife (*a*), and the rod being reduced and tempered for a short distance from the knife. The other blade (*b*) also runs into a fine-tempered end-piece, which rests against the solid probe point, either straight (H) or curved (H''), which screws on at *o*. The blades are withdrawn on removal of the pressure by the spring (K, Fig. 2). The extent of projection of the knives is regulated by the graduated wheel (L), turning

Fig. 3.

There seem to me to be required in a perfect urethrotome at least seven qualities—viz.: (1) to be used with one hand; (2) to cut either from before back or from behind forward; (3) to incise any part of the circumference of the urethra; (4) to be easily regulated, so as to cut to any depth, even when the blades are out of sight in the urethra; (5) to be of the smallest calibre possible when the blades are sheathed; (6) to be adapted to carry a guide bougie; and (7) to be easily cleaned. The value of the first of these may not be apparent; but with one hand you have a much more delicate sense of touch, which is all you have to rely upon in this operation. Who would hold a probe or a catheter with both hands? It is also advantageous to be able to grasp and steady the urethra with the free hand. To attain this the projection of the knives must be produced by flexion of the fingers, because this is more powerful than extension, and much more completely under our control—I presume in consequence of our habituation to use all instruments by the aid of the flexor muscles.

on the screw (*d*), and held in place after setting to the required number (French gauge) by the spring wedge (*c*). The whole tube (F) carrying the knives is only slotted for a short distance, and the steel rod is squared and fitted to a square box at the point *f*, Fig. 2. To clean the instrument screw off H. Turn the milled head (C) until the two parts of the rod which are united by a screw at *k*, Fig. 2, are separated. The anterior part of the rod with the blades can then be drawn out at the end (*o*). The spring box unscrews at *m*, Fig. 1. Fig. 3 is the conducting bougie, which can be screwed on at *n*, Fig. 1, in place of the probe point. The tube carrying the knife-rod is only slotted for two inches and a quarter, and is thus rigid. The square socket at *f*, Fig. 2, prevents twisting of the knives.

The instrument has been most satisfactorily made for me by Messrs. Hilliard and Son, Renfield-street.

WM. JAS. FLEMING, M.D.,
Surgeon to the Glasgow Royal Infirmary.

NINTH INTERNATIONAL MEDICAL CONGRESS.

IN the section on Medical Climatology and Demography of the Congress to be held at Washington in September next, the following scheme of subjects for papers and discusions has been prepared:—

1. Importance of the study of climatology and demography in connexion with the science of medicine. 2. What constitute determinate climatic characteristics. 3. The effects of climate on the human race as manifested in local demographic conditions; and of the several elements of climate as shown by coincident meteorological; morbility, and mortality statistics. 4. The question of acclimation. 5. Relative advantages of mountain and seaside resorts for recuperative purposes and as palliative or curative in certain diseased states of the system—segregation *versus* aggregation of invalids at health stations. 6. The therapeutic value of natural mineral waters. 7. Accurate records of prevailing sickness in any community a necessary factor in any comprehensive system of vital statistics. The responsibility of Governments to amply supply their people with the climatic and vital statistics of their respective countries. 8. Collective investigation, apart from aiding the study of the natural history of disease, as contributive of numerical data having a demographic bearing—(1) as to the kinds and proportions of prevailing diseases; (2) as to the absolute amount of daily sickness and consequent loss of time, occupation, &c. 9. Medical nomenclature considered in its practical relations to vital statistics. 10. The melioration of demographic conditions effected by preventive medicine. Influence of the physical well-being of a population upon its economy. Offences against moral and civil law in their medical relations to demographic circumstances.

Albert L. Gihon, M.D., P. O. Box 291, Vallejo, California, is president of this section; and Charles Denison, M.D., of Denver, Colorado; Isambard Owen, M.D., of Hertford-street, Mayfair, London; Dr. E. Bertherand, of Algeria; and Dr. A. Wernich, of Cöslin, Germany, are the secretaries.

THE LANCET.

LONDON: SATURDAY, APRIL 23, 1887.

THE deficiencies in the knowledge of the routine work of professional practice shown by our young practitioners fresh from the schools and from examinations, which have been so frequently referred to in our columns by ourselves and by numerous correspondents, were officially brought before the General Medical Council at its last session by Dr. GLOVER, and a committee to consider the question was agreed to. He has reprinted as a small pamphlet the statement in which he introduced his resolution. Hospital practice is very unlike general practice, and it is evident that the success and value of a practitioner depends much more on his familiarity with everyday diseases and their treatment than on his making exceptional diagnoses of phenomenal cases. How this routine knowledge can be best obtained without materially interfering with the general plan of his medical curriculum is the question which is before the committee for consideration, and everyone will agree on its importance. "A *limited* pupilage with a registered practitioner, and insistence on more clinical, therapeutical, and pathological teaching and work at medical schools," are the remedies suggested by Dr. GLOVER for this defect, and we hope that the committee will be able to make some useful recommendations for the guidance of parents and teachers. The difficulties, however, in framing any useful report are greater than appears at first sight. In England, owing mainly to the non-enforcement at the present time of an apprenticeship, which was formerly required by the Apothecaries' Society, medical education more and more tends to a commencement at a medical school or recognised hospital, and in Scotland this practice is almost universal, for in the quinquennium 1871–75 only seven students out of 1717 began their study elsewhere than at the Universities. Any enforced pupilage would therefore entirely change Scotch medical education, and are there sufficient grounds for doing this? Is the Scotch graduate so far inferior to his compeers in England and Ireland in the practical details of his work that his methods of early study must be radically changed? The average interval between the registered date of studentship and the date of a first qualification has been shown to be nearly five years, although forty-five months only is the period insisted on by the Conjoint Examining Board in England; and no regulation can be adopted which will in any way lengthen this period of study without materially affecting the number of those who are desirous of entering the medical profession. Pecuniary reasons alone will be sufficient to deter many, otherwise well qualified, from studying for the profession if an increased length of probationary study be required. Moreover, another factor besides the student must be dealt with. The committee will have to judge whether every general practitioner is fitted for the duties involved in taking pupils. Pupilage with a scientific practitioner is the greatest possible boon; pupilage in other cases may degenerate into something but little removed from drudgery, and very few parents outside our profession can be expected to discriminate between the two extremes. Besides details of medical practice, a pupil may reasonably expect to be taught chemistry and physics, a little botany, and the rudiments of materia medica in his first year; and this should be secured, either by the practitioner being really able as well as willing to undertake these obligations, or by his seeing that an efficient teacher can be found within ready distance. Dispensing medicines and visiting ordinary cases are very important, but they should not occupy the whole time of a pupil between his leaving school and his entering at a hospital, if the pupilage is to extend over more than two or three months. Again, the more select in the status of the patients the practice may be, the less can the pupil learn, so that it is only in mining, factory, Poor-law, and similar large practices that he can gain the essentially practical knowledge of infantile and common diseases that is urged on him as a necessity. Dispensing and book-keeping are not now so formidable as in former days. Dispensing has been quite changed within late years. Mixtures, concentrated infusions, and pills are now largely used according to set formulæ, and have materially lightened the work which made great inroads on the time of the older practitioners; and anyone quickly learns to keep his books on his own plan and system. The proper writing of prescriptions is another and a different matter, but we question if this can be judiciously taught until late in a student's career, and it may be and should be made a prominent feature in the instruction obtained from out-patient class-rooms. We would like to ask the committee to seriously weigh these arguments for and against an early pupilage even for a limited time, and to take the opinions of practitioners in the provinces and in the metropolis, and also of some of our younger teachers brought up under the new *régime*, as to whether six months devoted to general practice spent between the second and the final examinations would not be a better alternative. There are, however, objections to this course also, for it would interfere with the regulations for resident appointments in many medical schools, which are so valuable to the student from every point of view; and if required to assist in working a general practice at this period of his curriculum a student would probably ask to be paid for his services, instead of having to pay a premium as under the old apprenticeship system. To Dr. GLOVER'S other suggestions for utilising country hospitals and workhouse infirmaries as centres of medical education no objection whatever can be taken, and the difficulties surrounding their practical application could be easily removed. We hope that the committee will draw up a reasonable and workable scheme, so that the great advantages held out by the proposition may be realised to the medical student.

IN an article last week we commented on certain Bills which have this session been introduced into Parliament, and which have as their object the improvement of house drainage, but which take no heed of the many conditions connected with the dwelling which are also concerned in prejudicing the health of the inmates. Professor CORFIELD has now brought before the profession other circumstances

Digitized by Google

which affect health, and has shown much reason for thinking that so simple a matter as faulty gas fittings may be responsible for some of the ill health which has hitherto been attributed to defects in house drainage.

Some three years ago Professors W. T. SEDGWICK and W. RIPLEY NICHOLS contributed a paper on this subject to the Massachusetts State Board, in which they discussed the relative poisonous effects of coal and water gas. They contended that such harm as resulted from the inhalation of small quantities of these gases was due to carbonic oxide, and they proceeded to show that water gas, inasmuch as it contains more carbonic oxide than coal gas, would necessarily be more injurious in its effects. Some account of the symptoms is given both where the quantity breathed was large and where it was small; the latter producing intolerable headaches in a lady previously in fair health, but who happened later to occupy a bedroom in which was an escape of water gas from a leaky pipe below the floor.

Professor CORFIELD has now related to the Society of Medical Officers of Health a series of cases observed by himself in which health appears to have been injuriously affected by small escapes of coal gas into sleeping-rooms through defective gas fittings. The symptoms he described are not identical with those mentioned by American writers, the more prominent in the English cases being relaxed and ulcerated sore-throat. This difference, however, may not have any importance as affecting the evidence that the illness was dependent upon the condition to which the writer attributes it. It is probable that loss of health might show itself in one person by headache and in another by soreness of throat, and the number of cases which have yet been observed is not sufficiently great to warrant any generalisation on this point.

Apart from the interest which attaches to observations by so trustworthy an authority, a further lesson is to be learnt. There has for some years been a growing tendency on the part of many to accept as an assured fact that throat illness is necessarily evidence of defective drainage. Dr. CORFIELD'S cases are of value in showing that this assumption is not safe, and if later we are led to conclude with him that coal gas may produce results not dissimilar from those usually attributed to the air contents of drains, the more necessary is it that we should be prepared to find still other causes which may affect the inmates of a house. The difficulties which surround all questions of this sort are no doubt very great, and it is not easy to see how such exact evidence as we desire is to be obtained. It is enough at the present moment to allow that Dr. CORFIELD has indicated the necessity for more extended observations, and for more reserve in the acceptance of a too general belief that the occurrence of throat illness must be due to faulty drains. While, therefore, we fully recognise the importance of a perfect drainage system, we would desire to repeat our recent warning that householders must not assume that an expenditure of money in improvements of this character will ensure them against further ailment. There is, indeed, much need for more investigation into local causes which may affect health, and those skilled in etiological inquiry will render greater service by seeking in the first instance the cause of disease, than by effecting the improvement of only one of many possibly unhealthy conditions.

IF the affiliation of Hospitals and Dispensaries is to pass from the academic region into that of practical medico-social politics, the beginning of the passage may be expected on Tuesday next, when a vote will be taken in the Medical Attendance Organisation Committee on the following motion, proposed by Mr. BOUSFIELD and seconded by Mr. TIMOTHY HOLMES:—

"That the true functions of the out-patient departments should be mainly consultative, and that their committee and medical staffs be requested to confine their patients, as far as possible, to those who have been previously treated at provident dispensaries or by ordinary medical practitioners."

Already a lively discussion on this motion has taken place, in which Dr. ORD, Mr. TIMOTHY HOLMES, Dr. J. C. STEELE, Dr. GILBART SMITH, Mr. NELSON HARDY, and others took part. All those who hold strong opinions, or who feel the importance of the question as affecting either medical education or public opinion concerning hospitals, might rely confidently on a short hearing on Tuesday from the committee, which meets at 5, Lamb's-conduit-street. Dr. GILBART SMITH on Tuesday last described the views of Mr. NELSON HARDY on the abuses of the out-patient department as "poetry." This is a euphemistic expression which breaks no bones. It represents the views of the ardent physicians and surgeons of the out-patient departments who feel that interesting cases must be found, and that crowds must be forthcoming to supply them. They regard such visions as those of Mr. HOLMES and Mr. NELSON HARDY as "utopian" in the present state of society, when the strata of poverty in such a community as that of London are so deep and dense. Students, too, must be attracted and employed, and for this end numbers are an advantage. Numbers have a charm, too, for hospital treasurers and secretaries, when the reports are made up. They seem to swell the sound of the good done and the charity dispensed. Moreover, as Dr. STEELE puts it, the hospitals are reluctant to institute a sort of relieving officer, and are disposed to regard inquiry into the means and character of every applicant as an inquisitorial and ungenerous process. It would be folly to underrate the force of some of these considerations, or of all of them combined. But there are some others to be set off against them. The out-patient department of the hospitals is their weakest and most vulnerable spot. It has led to more adverse criticism of hospitals than any other part of their administration. The public would be deprived of half its excuses for not supporting hospitals more generously if the grievances of the out-patient department were removed. Nay, more, the hospitals would have the credit of being the most powerful promoters of thrift and providence. It is not proposed absolutely to close the out-patient department, but to restrict it to a more serious class of cases, recommended by dispensaries or practitioners. With such limitations cases would be carefully examined and prescribed for, without overtaxing the hospital staff. If the commoner cases were in this way kept in the dispensaries, they would not necessarily be lost to the use of students and for educational

Digitized by Google

purposes—for it is part of the scheme of affiliation, or might be made so, that the dispensaries should be brought into the service of medical education. Then, as a still more convincing argument, some hospitals have actually carried out this reform. At Guy's, at St. Thomas's, and at St. George's there is a restriction of the number of cases of out-patients, and it is found to work well. Under all these circumstances we bespeak for the resolution quoted above a fair hearing. No doubt its promoters would agree to any modification likely to make it more workable. The objection to all such motions is their lack of feasibility. What is wanted is a resolution to satisfy, not the social and medical philosophers in Lamb's-conduit-street, but the medical profession, medical teachers, and the public.

AT the recent meeting of the Council of the Royal College of Surgeons, as we announced last week, "the seventh report of the Committee on Charters and Bye-laws, containing the draft of the new supplementary Charter to give effect to several alterations in the Charters agreed to by the Council, was approved and adopted, and it was resolved that the necessary proceedings be taken to submit the same to the Privy Council." It will not be amiss, therefore, to remind our readers of the principal alterations which the Council proposes to ask for in the constitution of the College. They may be briefly summarised as follows. Firstly, to permit voting by means of voting papers as an alternative to voting in person, as at present; secondly, with respect to the eligibility of Fellows for election to the Council, to reduce the term of qualification from fourteen to ten years; thirdly, to abolish the restriction as regards Fellows who are candidates for the Council which prohibits their practising as Apothecaries, and requires them to be in the *bonâ fide* practice of Surgery; fourthly, to abolish the Midwifery certificate of qualification; fifthly, to enlarge the powers of the Council as to the election of Members of the College of twenty years' standing to the Fellowship—i.e., to give the power to elect Members of that standing to a number not exceeding ten instead of only two such Members, as at present; and lastly, to give the power to elect two Honorary Fellows in each year, whether Members of the College or not, such Honorary Fellows to have no vote for the election of members of the Council. It is worthy of note that none of these proposed alterations were primarily proposed by the Council. They all had their origin outside. The Council, it is true, did originally propose a few alterations; but these were of only minor importance and did not materially affect the constitution of the College except so far as they will secure to the Council greater freedom with less responsibility, and get rid of a certain amount of external and salutary check and control. It is both significant and characteristic that, in spite of emphatic and repeated expressions of opinion by large numbers of Fellows and Members—amounting in the aggregate to many thousands,—the Council persists in its determination to ask for a new Charter which studiously ignores the important and radical recommendations twice carried in general meetings by overwhelming majorities, and without appreciable or calculable opposition. These recommendations are chiefly two—first, that in some way and in some degree Members of the College shall, under conditions, be empowered to vote in the election of the Council and be eligible to sit in the Council; and, second, that no alteration shall be made in the constitution of the College or in its relations or in any of its bye-laws without the consent of the Fellows and Members specially convened to consider and discuss them. These reasonable demands the Council apparently both rejects and resists. It is obvious that the matter will now have to be fought out before the Privy Council. There can be no doubt that after the confirmation of the minutes at the next Council meeting of the College the new Charter will promptly be submitted to the consideration of the Privy Council. Before this is done the Charter as now drafted should be submitted to a general meeting of Fellows and Members. It is only right that they should be able to understand definitely and in detail what the Council are applying for, whether the alterations be acceptable and agreeable or not. This is impossible unless the Charter itself, as it undoubtedly should be, is open to their inspection. The Council can surely have no objection to so reasonable a demand, and will, we trust, lose no time in calling a general meeting for the purpose. At the least, printed copies should be available for those who care to apply for them.

Annotations.

"Ne quid nimis."

WARNING TO THOSE NOT REGISTERED.

IT cannot be too explicitly stated that Tuesday, May 31st next, will be the last day on which degrees and diplomas can be registered, unless they have been conferred after a qualifying examination in medicine, surgery, and midwifery, held expressly for the purposes of, and under the conditions stated in, the Medical Act of 1886. We therefore counsel our readers in all parts of the empire who intend to register on old diplomas to do so without delay.

ARMY MEDICAL SERVICE.

IN accordance with the promise made to the deputation which recently waited upon him on the subject of the relative rank of the army medical officers, the Secretary of State for War has reconsidered the terms of the Warrant, and, "after consultation with the Director-General of the Army Medical Department," has altered them as follows:—"125*a*. Officers of departments of our army, not having honorary rank, shall rank as follows for purposes of precedence and other advantages attaching to corresponding military rank; but this shall not, except as provided in articles 265, 348, and 307*a*, entitle them to military command of any kind, to the presidency of courts-martial, courts of inquiry, committees, or boards of survey, or to precedence in their own departments over officers holding a superior departmental rank." This is followed by the classification of officers as given in the previous Warrant, with this difference, that they are stated to rank "as" instead of "with" the corresponding military grades. It is gratifying to us to find that the course adopted by the War Minister accords with that which we pointed out as being a satisfactory mode of solving any doubt which might be raised as to the military status of the various grades of medical officers. (See THE LANCET, April 2nd, p. 688.) But there is a question connected with the Army Medical Staff to which we attach great importance, and which, we fear, has been lost sight of in this scare on the subject of relative rank—that of rewards for professional services. Rewards for medical officers ought not, as at present, to be dependent

Digitized by Google

upon the recommendation of the military officers alone, and to be given only for services in the field; they ought to be conferred on the nomination of the Director-General, to whom all reports as to services rendered should be referred, and with whom the appreciation of these should rest and the consequent action upon them should originate. It has hitherto been the practice to grant honours and rewards solely upon the recommendation of the military authorities, who certainly cannot be deemed the best judges of the value of professional work. One result has been that, while for service in the field a fair amount of recognition has been bestowed, the more arduous work, in the hospitals and in the conflict with epidemics or in the important labours connected with the preservation of the health of the soldier by the adoption of sanitary measures, has been practically ignored. We would desire to claim for the head of the Army Medical Service a more potent voice in its practical working than has hitherto been accorded. No measure affecting the department should be introduced without his being taken into council, as we fear was the case with the last Warrant; and all rewards to medical officers should originate with him, or, if from any other source, should pass through his hands and be subject to his comments before being submitted to the War Minister. Were this the case, we should no doubt have rewarded for professional work officers who, however meritorious, are at present passed by without notice, because the military authorities, with whom the initiation now rests, are not competent to form a correct estimate of the value of such special service. It is not too much to expect that the head of an important scientific branch of the army, the labours of which can be truly appreciated only by an expert, should be consulted on all questions affecting its position and its mode of action, and that he should have the power to recommend to the War Minister for rewards or honorary decorations such officers as he may consider to have earned a title to them by valuable professional work.

POST OFFICE AUTHORITIES AND INFECTIOUS DISEASE.

IN a recent report on Kensington Dr. Dudfield draws attention to an important point in connexion with the existence of infectious disease in the families of Post Office servants. In 1882-83 correspondence was held with the Postmaster-General on the same subject, the Kensington vestry being desirous of having reported to them by the Post Office medical officers the existence of any such cases of illness, in order "to secure the isolation of the cases," and "to facilitate the removal of the sick to hospital when they cannot be safely treated at home." In answer, the Post Office authorities stated that a notice had been issued to the numerous medical officers of the department, in which they were instructed that, if in their district it be not already the rule to give notice of such disease to the sanitary authority, it would be well that such a rule should be introduced in the case of Post Office servants. But the letter, referring further to the question of admission to hospital, said that the department was not prepared to adopt compulsion. Within a month during the early part of this year Dr. Dudfield heard of three occurrences of scarlet fever in the families of postmen. The postal authorities very properly relieve their men from duty during such occurrences, and it appears that in these three cases they refused to allow them to resume their work until disinfection had been carried out. And it was the need for getting this process done that brought the cases under the notice of the vestry. Dr. Dudfield had, we think, ground for complaint, and hence he communicated the facts to the chief medical officer of the department, who in turn says that forms had been supplied to the postal medical officer of the parish for the purposes of communicating with the sanitary authorities, together with a recommendation to use them, but "the department is not prepared to employ compulsion in the matter." So far as we were able to judge, the question of compulsion in the former correspondence related to removal to hospital, and in this respect we entirely concur with the Postmaster-General that Post Office *employés* should not be treated differently from other members of the public. But we do think that, as regards notification, the department, which is maintaining the sick family at the public expense, might properly let the authority know, and might rightly require that the forms issued should, in every case, be used for the purposes indicated. It is known how largely children from such families as those of letter carriers attend elementary schools, and the Post Office department should not withhold from the sanitary officer the information which he needs in order to give effect to the provision of the Education Code issued by another Government Department as to the exclusion from school attendance of scholars living in infected houses. The Post Office authorities seem to claim some credit from the fact that the information does, owing to their requirements, at last reach the sanitary authority. But it is practically useless for the principal preventive purposes when it comes to hand only at the termination of the illness; and if it is the intention of the Post Office hereafter to require their servants to apply to the local authority for the purposes of securing disinfection, they might at the same time have regard to public health requirements, and instruct their officers to give the needed information at the onset of the disease, when it can be most usefully employed for all parties concerned.

FASTING FOR THE SAKE OF SCIENCE.

THE case of M. Cetti, who recently undertook, in the interests of science, to fast for thirty days in Berlin, was brought before the Medical Society of that city at a recent meeting by Prof. Senator. It should be said that the observations were not prolonged beyond eleven days, M. Cetti being informed that there was no necessity, from the scientific point of view, for him to continue his fast beyond a fortnight. During this period he was subjected to very careful observation. He is twenty-six years of age, and his weight was reduced from 57,080 grammes to 50,650 grammes during the eleven days, an average daily loss of 585 grammes. Starvation was not absolute, since he was allowed to drink water *ad lib.* He also smoked cigarettes, which, however, could not be shown to have had any influence on nutrition. His general condition remained very good. The quantity of chloride of sodium eliminated in the urine sank from eight or ten grammes on the first day to less than one gramme on the last days. The temperature was always within normal limits, attaining on the seventh and eighth days nearly the physiological maximum. On these days it reached 37·4° C. (99·3° F.), at other times varying between 36·4° and 36·8° (97·5-98·6° F.); but it never rose above that level. On these two days he was not very well, complaining of colic and suffering from hiccough. The pulse was normal, but very excitable, merely sitting up in bed causing an increase of the rate from 76 to 120. Professor Senator did not enter into further details, which are reserved for later publication, but described the very thorough methods to which M. Cetti was subjected. These comprised accurate measurements of the body and estimations of the excreta, examination of the blood as to its corpuscular richness and hæmoglobin capacity, and sphygmographic studies of the pulse. Observations on the vital capacity and estimation of the oxygen and carbonic acid of respiration were made daily. Dynamometric records were kept. The urine was most thoroughly investigated, chiefly by Drs. Müller and Munk, the analysis including estimations of urea, chloride of sodium, phosphoric acid, sulphuric acid, soda, potash and

Digitized by Google

ammonia, indol, phenol, acetone, and diacetic acid, and also of the digestive ferments which have been recently shown to be present in urine in certain conditions and absent in others. The saliva and the fæces were also submitted to examination. Professor Virchow, who was associated with Professor Senator in the observations, added a few remarks upon the object of the experiment; and M. Cetti, who was present at the meeting, gave his reasons for undertaking the fast, and stated that he had felt no appetite or hunger until he was told that on the next day he would be allowed to eat. The desire then returned to him at once, and he kept awake half the night. He expressed himself very gratified with the kindness and attention bestowed upon him by the scientific men who had taken him in charge.

THE EXAMINATIONS OF THE PHARMACEUTICAL SOCIETY.

THE *Chemist and Druggist* of April 9th contains the reports of Dr. Headlam Greenhow, the Government visitor to the examinations of the Pharmaceutical Society, on the examinations held by the Society in the years 1885 and 1886. The main facts are of considerable interest to the profession as well as to the public. The examinations reported on are three in number: the preliminary, the minor, and the major. The preliminary examinations are conducted by the College of Preceptors. In 1885, for the first or preliminary examination, there were 1278 candidates. Of these 588, or 46 per cent., were rejected. This proportion of rejections is said to be rather less than usual. For 1886 the number at this examination was 1305, of which 673, or 51·57 per cent., were rejected. The subjects are Arithmetic, Latin, and English. Arithmetic is the rock on which most of the candidates come to grief; in 1885, 209 failed in it alone. If the number of those who failed in it and in one or both of the other subjects be added the number of failures in arithmetic is raised to 476. In 1886, 238 failed in arithmetic alone, and 323 in it and one or both of the other subjects. The failures in Latin in 1885 were 252, and in English 240. Dr. Greenhow very properly insists on the seriousness of deficiency in arithmetic, a knowledge of which subject he regards as not only a test of a fair elementary education, but as absolutely requisite in dispensing and chemical operations. We are glad to see, in spite of indications of carelessness of the medical examining bodies on the subject of Latin, that the Society still insists on a knowledge of this subject in its candidates. In the minor examinations for 1885, of 744 candidates only 255 passed; 489, or 65·7 per cent., were rejected. Of the rejected candidates, 81 failed on account of general weakness in all the subjects, 171 in practical dispensing, 70 in chemistry, 64 in pharmacy, 43 in reading prescriptions, 22 in materia medica, 27 in botany, and 11 in two or more of these subjects. In 1886 the rejections at this examination were 530 out of 824 candidates, or 63·1 per cent. The subject in which the largest proportion of them failed was practical dispensing, which brought 205 candidates to grief. In chemistry 71 failed. The candidates for the major examination are much fewer, being 87 and 90 in the two years respectively, the rejections being 46·0 per cent. and 43·3 per cent. It is not the least proof of Dr. Greenhow's fitness for this duty that he has carefully considered the large proportion of rejections and has made suggestions, in the interest of fair examination, for an extension of the *time* in the minor examination, as well as an extension of the number of articles to be dispensed. He is quite satisfied of the general fairness of the present examinations, but thinks more *time* should be given. He urges, too—a very important point,—that the preliminary examination should be passed before the student is allowed to proceed with his proper studies. We are surprised that this is not already required. It is a grievous unkindness to students not to be severe in this requirement.

THE JUBILEE AND THE UNIVERSITY OF LONDON.

AT a special meeting of Convocation of the University of London on the 19th inst., the chairman read a communication from the Prince of Wales, inviting the co-operation of the University in the establishment of the proposed Imperial Institute. It was then resolved, on the motion of Dr. Baines and seconded by Mr. Lemon, that the jubilee of the University be celebrated this year, and that it is desirable to associate therewith the commemoration of the jubilee of Her Majesty's accession to the throne; and that a special committee be appointed to carry out the wishes of Convocation in this respect. Dr. Quain moved and Sir A. K. Rollit seconded the following resolution: "That an appropriate method of carrying out the wishes of Convocation as expressed at this meeting would be the placing of a statue or other similar memorial of Her Majesty in the University building. That this proposal is especially appropriate, inasmuch as the University was founded by a Charter granted by Queen Victoria, that Her Majesty is the visitor of the University, and was graciously pleased to open the University building in person, and that Her Majesty has recently granted to this University the high privilege of presenting an address to Her Majesty upon the throne in like manner as is allowed to the Universities of Oxford and Cambridge." The motion was unanimously agreed to, and the proceedings terminated with the passing of a third resolution, moved by Sir Philip Magnus and seconded by Mr. Lemon, to the effect that the statue or other memorial should be presented to the University at a special meeting or reception, at which the presence of Royal and distinguished persons should be invited.

EARLY WELSH MEDICINE.

IN our appreciation of the great advance in medical and surgical knowledge which has taken place in recent times, we are but too apt to undervalue the services of those who have laboriously laid the foundation of our art in remoter ages. Of a part of this indebtedness we are reminded by a short but interesting paper on "Early Welsh Medicine" by Mr. P. Rhys Griffiths, from which it appears that not only was the art of medicine cultivated by the Britons at a very early period, but that the Cymric practitioners during the mediæval and perhaps even in the earlier Christian epoch enjoyed a status and exercised a degree of skill by no means contemptible. Tradition tells us that up to the time of the Welsh king, Prydain (1000 B.C.), the knowledge of medicine and other sciences was usually found in connexion with the priestly office. After that date men of science and physicians appear to have formed a group by themselves. Regarding their methods there is little information, save that they seem to have relied chiefly on herbs as means of treatment. It is not till we reach the year 930 A.D. that any very definite information on medical matters is obtainable. About this time we learn from an Act of Howell the Good certain interesting particulars as to the position of the royal medical attendant. This functionary was evidently a person of some consequence. His "lodging was with the chief of the household," he held his land free, was allowed a horse, and received fees according to a fixed scale. Early in the thirteenth century the name of Rhiwallon, household physician to Rhys Grug, prince of South Wales, attracts especial notice. He was the most famous of the early Welsh physicians of whose life and work we possess reliable information, a copious contributor to the literature of medicine, for his time a practitioner of a very high order, and a man of true professional principle and personal integrity. The teaching and practice of Rhiwallon and his three sons were probably inspired in a greater or less degree by that of Hippocrates, who is more than once referred to in their writings, though the works

Digitized by Google

of the Persian and Roman teachers were also included among their studies. In this connexion it is noticeable that the humoral theory of disease was familiar to these early British physicians, while the prominent place assigned in their treatment to dietetics is no less significant. In regard to diet, indeed, they evidently possessed a fairly accurate though an empirical idea of what was or was not physiologically suitable. In diagnosis they relied almost exclusively on the evidence afforded by the general bodily condition and the appearance of excreta. The heart, pulse, and temperature revealed nothing to them. Their materia medica consisted almost entirely of organic substances, for the most part vegetable, and included some of the sources of our own most valued remedies, such as digitalis and the poppy. The plants employed in treatment were home-grown, as might be expected, and were administered either as external applications or in the form of infusions or decoctions. While thus occupying in medicine the position of herbalists, and nearly ignorant of scientific method, these early practitioners were in some respects well advanced in surgical skill. They were good lithotomists, they treated abscesses in the lung or brain by puncture and trepanning, and they incised the chest in empyema. In some other ways their ideas, as may be imagined, were of the most primitive order. Tumours they treated by applying the rump of a live fowl, feathered, to the part. Charms were probably less used at this than at an earlier epoch, but their employment in medical practice was not yet by any means unknown. The early practitioners of Wales appear, therefore, to have proceeded in their treatment on much the same lines as their brethren elsewhere, and were probably rather more than less intelligent in the methods they were wont to use.

ANTHRAX IN CHESHIRE.

FOR some time past alarming notices have been appearing in the local papers in reference to the alleged occurrence of anthrax on a farm in Cheshire, and questions were asked in Parliament on the subject. To these questions the usual stereotyped answers were given, containing, however, rather more than the usual amount of official wordiness. It was alleged, among other things, that the outbreak was due to "the insanitary condition" of the farm! We venture to say that "insanitary condition" never did and never will produce anthrax. It is fortunate that Dr. Hime, who is well qualified for the work, has been enabled to examine into the question on the spot, as some confusion has now been introduced into the matter by official declaration as to the simultaneous existence of "occult" swine fever. He has been resident on the farm for some days, and has made several post-mortem examinations of animals which have died there. He has stated that all these animals had anthrax, and that no symptom or sign of swine plague was to be found either before or after death. Dr. Hime also prepared numerous microscopical mounts, which, when shown to competent observers, left no doubt on their mind that the disease was typical anthrax. But there were numerous peculiarities in the case. In fact, the occurrence of anthrax in the pig is in itself uncommon, and its possibility is distinctly denied by Klein over and over again. But the fact that the animals lately attacked have survived so much longer than the first victims is noteworthy, the latter having mostly perished rapidly with symptoms of splenic apoplexy, while the later cases have lasted six, seven, and even eight days. Again, the splenic disorganisation was not nearly so marked in the latter cases. Dr. Hime caused very energetic steps for prevention to be taken. All animals which died during the visit were burned, and not buried according to the Privy Council Orders; perchloride of mercury was liberally used instead of chloride of lime. The floors were ordered to be dug up and the earth burned, the walls to be scraped and disinfected with the perchloride, &c. The unfortunate farmer has not only lost some £600 worth of stock, but has suffered grievously from the restrictions of the authorities. Because some pigs were ill, all the healthy stock and their milk &c. were put under a ban. Dr. Hime strongly represented the unnecessary hardship of this to the authorities, and we believe considerable relief was then afforded. We hope to be able shortly to give a fuller account of this remarkable outbreak. The disease has also made its appearance in Romney Marsh.

A MINISTER OF HEALTH.

IT is announced that Earl Cadogan, Lord Privy Seal, and the Right Hon. C. T. Ritchie, President of the Local Government Board, have been invited to join the Cabinet. The news of Mr. Ritchie's promotion will be received with much satisfaction by those who have the health interests of the country at heart. We have many times commented on the need for this recognition of the importance of the duties which devolve upon Mr. Ritchie's department; it is indeed extraordinary that the country which sets an example to all other nations in the estimation in which it holds sanitary progress, both as regards life and commerce, should ever exclude from the Cabinet the statesman who presides over the branch of administration which is concerned with this subject. In Mr. Ritchie's case there is the further argument that his high abilities must render his services of especial value. We fear there is not just now much hope for domestic progress, but Mr. Ritchie's presence in the Cabinet should ensure immediate attention being directed to those subjects in which the future of England is involved, and certainly amongst these must be reckoned the placing of the sanitary service on a better footing than at present. The hope that has for long been entertained, that improved methods of local government would be seriously undertaken by successive Ministries, has been hitherto grievously disappointed; but recent public statements of the President of the Local Government Board have shown that they have not been forgotten. Probably all that is wanted is the necessary opportunity for bringing them before Parliament. We trust that Mr. Ritchie's relation with the Local Government Board may be continued until this is afforded, and that he may have the direction of the legislation which we may now anticipate will follow.

THE TITLE OF "DR." AMONGST DENTISTS.

THERE has been a keen discussion in one of the dental periodicals about the use of the title of "Dr." by graduates of American colleges who are in practice here. All the writers equally disclaim any intention of decrying the D.D.S. or D.M.D. which is legitimately gained after a reasonable term of residence, but their arguments are aimed at those who, whether licentiates of one of our colleges or *sine curriculo* men, go out to America to obtain a diploma, too often a bogus one, and then return to practise under the title "Dr." It is freely admitted by the leading Americans themselves that the practice of dental surgery in all its branches is fully as well taught, theoretically and practically, in our dental schools as across the Atlantic. The editor of the *Journal of the British Dental Association* suggests that the title "Dr." should be dropped by those dental surgeons holding it in this country. Those conscientious practitioners, whether English or American, who are always welcome in our midst, might or might not agree to this; but those who abuse the title certainly would not, and it is the abuse that we wish to attack. The public, we think, do attach considerable importance to the title "Dr." amongst dentists, and therefore we would point out that this term, used in virtue of the D.D.S., does not signify a *medical* qualification, and, when honestly obtained, is

Digitized by Google

similar, and by no means superior, to our L.D.S. We are heartily glad to see that the Americans are awakening to the fact that their degree is fast falling into disrepute, and only last month a "diploma mill," with the title of "Druidical University of America," had its charter repealed; but it is not only these illicit manufactories that need looking after, but the recognised universities where diplomas are given after a few weeks' residence.

THE GASTRIC JUICE IN CANCER OF THE STOMACH.

PROFESSOR A. V. PELIA, in a "preliminary note" published in the last number of the *Vrach*, states that he has observed in several cases of suspected carcinoma of the stomach that the gastric juice, even after the addition to it of hydrochloric acid or pepsine, or both, remained incapable of peptonising coagulated albumen and fibrine; and not only so, but when added to normal or artificial gastric juice possessing peptonising power this cancerous gastric juice actually destroyed that power, showing that its own property was not of a merely negative character but of an active anti-fermentative nature. Professor Pelia suggests that in cancer of the stomach some new chemical principle of the nature of an anti-ferment may be secreted in the stomach. This is, he thinks, secreted also in these cases by the kidneys, for he has been able several times to show that the urine of a patient with anti-peptonising gastric juice possessed a similar anti-fermentative power. He remarks that Cahn and Mering have recently shown that an absence of free hydrochloric acid in the gastric juice is not a proof of the existence of cancer of the stomach; but he does not wish to express any opinion himself on the question of the significance of hydrochloric acid from a diagnostic point of view.

SANITARY WORK IN MUCH WOOLTON.

DR. B. B. JOLL'S report on an outbreak of fatal measles in the Much Woolton urban district raises two points worthy of notice. In the first place, the sanitary authority appeared to be much astonished at his attendance at their meeting, and the chairman had to explain to them that their medical officer of health had not come there to assert any right, but only as a matter of courtesy and with a view to any explanations that might be required on his report. That such a statement should have been necessary implies, we fear, a very scant appreciation of their duties by the authority. No medical officer of health has an actual right to be present at all meetings of the sanitary authority, unless indeed such right forms a condition of his appointment; but many such officers do make it a practice to attend, and many authorities either require or are only too glad to have the advantage of their presence. The Order of the Local Government Board requires the attendance of the medical officer of health at such stated times as the sanitary authority may direct; for it is assumed that such authorities stand in need of their skilled adviser in matters relating to health whenever sanitary topics are under discussion, in precisely the same way as they need the attendance of their clerk when legal and administrative topics are being dealt with. The episode at Much Woolton implies that hitherto the sanitary work has been done without the sanitary adviser of the Board; and this is probably the explanation of the second point to which we would advert. We refer to a proposal on the part of this authority, with a population bordering on 5000, and in whose district twenty-eight deaths from measles have just occurred in a single month, to make an annual payment to the Prescot Hospital, now in course of erection some six or seven miles away, for the use of one solitary bed for the infectious diseases calling for isolation within their jurisdiction. Dr. Joll has cause to protest against anything so utterly ridiculous. If the Much Woolton Board have no intention of giving their district the benefit of hospital accommodation such as the Public Health Act intended them to provide, they had far better say so at once than go through the form of making a provision which is void of substance.

DEATH OF DR. ALFRED MEADOWS.

WE regret to announce the death, on the 19th inst, of Dr. Alfred Meadows, after a comparatively short illness. The deceased, who was held in high esteem by the members of the profession, was recently appointed a Justice of the Peace for Middlesex, and was well known in Masonic circles. We hope in our next issue to give a more detailed account of his career.

Sir Edward H. Sieveking presided at a meeting of the staff and students at St. Mary's Hospital on Wednesday last, to express the deep regret felt by all at the sudden death of Dr. Alfred Meadows. Mr. Field, the dean of the school, read letters from gentlemen unable to be present expressing sympathy. The chairman, in a touching speech, alluded to Dr. Meadows' many good qualities and the irreparable loss sustained by his death, and then called on Mr. Edmund Owen to move the following resolution, which was seconded by Dr. Montagu Handfield Jones, and carried unanimously: "That the staff and students of St. Mary's Hospital have received with poignant regret and sorrow the intelligence of the death of their beloved friend, Dr. Meadows; that young and old who have had the advantage of intercourse with him have learnt to admire his excellent qualities of head and heart; and that the staff and students of St. Mary's Hospital request Mrs. Meadows and Miss Meadows to accept the assurance of their profound sympathy in the irreparable loss they have sustained." A service will be held at All Saints', Margaret-street, to-day (Saturday), at 11 A.M.; and a special train will leave Paddington at 2.30 P.M. for Colnbrook, where the interment will take place.

THE BOWEL LESION IN TYPHOID FEVER.

How far ought the intestinal ulceration met with in typhoid fever to be considered pathognomonic? Is the detection of ulcers in Peyer's patches, presenting none of the characters of the tuberculosis or dysentery, to be taken as proof of typhoid fever, even in the absence of well-marked clinical symptoms? Are we justified in believing in latent typhoid from post-mortem evidence alone? Such are the questions which are suggested by an interesting *brochure* recently published by Dr. Vandyke Carter, upon "A Peyerian Ulcer Lesion of the Small Intestines, apparently new" (Bombay, 1886); and the answer he would impel us to give to them would be a decided negative. The material upon which he bases his paper consists of about ten cases, in natives (in whom typhoid fever is rare) suffering from symptoms described as remittent fever, and after death, which in some cases was due to perforative peritonitis, exhibiting more or less extensive ulceration of the small intestines. Constipation rather than diarrhœa was the rule; and in not more than one case did the "fever" run the course of typhoid. But Dr. Carter does not rely on clinical grounds to establish the non-identity between the intestinal lesion in these cases and that present in typhoid fever. He subjects the type of ulceration to a close scrutiny, and points out several prominent features of difference, the most striking being the absence in his cases of the excessive swelling and infiltration of the Peyer's patch that precede the stage of ulceration in typhoid fever. He inclines to the belief that these non-specific ulcers are produced by embolic or thrombotic plugging, and that this depends on septic conditions. That septic causes are adequate to produce in-

Digitized by Google

testinal lesions of this kind is not to be gainsaid; and we think that Dr. Carter has made out a case for further investigation. At the same time, with the knowledge we have of the various forms assumed by typhoid fever, or at any rate by cases classed together as typhoid, and the great variety and extent of the intestinal lesion in cases of this disease, we may hesitate at first to accept his conclusion. A less cautious observer than Dr. Vandyke Carter would doubtless have been satisfied with the detection of the numerous ulcers in the favoured seats of election, and the occurrence in many cases of perforation, to declare that the cases came under the head of typhoid fever, modified it may be by the conditions under which the disease occurred. Hitherto we have been led to rely upon the ulceration of the intestines as the only positive criterion of this disease; but now it will be necessary to review our position in regard to it, and it may be that we shall have to fall back upon the detection of the typhoid bacillus to determine the diagnosis.

MEDICAL OFFICERS OF HEALTH.

OUR attention has been directed to a recent appointment in which a gentleman has been selected as medical officer of health who possesses no sanitary certificate, in preference to another holding that of the University of Cambridge. It is but natural that some disappointment should be felt by the unsuccessful candidate, who has spent time and trouble in the acquirement of knowledge which would undoubtedly have been useful to the local authority had they elected him. It must, however, be recollected that these distinctions are not yet understood by the public, and that other circumstances than those of the possession of certificates frequently guide these bodies in the selection of officers. Sanitary medicine is still in its infancy, and it is only within the last few years that the special knowledge which it requires has become appreciated by examining bodies, and only during the present year that the General Medical Council have recommended that the subject should be separately taught at the medical schools. It would therefore be expecting too much if we were to cavil at a local authority for neglecting to recognise the value of the evidence of special training which is afforded by the possession of certificates in sanitary science. Progress is necessarily slow, but the disappointment which is felt by such a circumstance as that to which we refer must serve as no discouragement to those who are looking forward to a career in public health. We do not doubt that in the future preventive medicine as a public service will occupy all the position it deserves.

EPIDEMICS OF MEASLES.

THERE have been during the past six months numerous severe epidemics of measles. In the metropolis there was a diminution in the fatality from this disease during 1886, as compared with the average for the decennial period 1876-85, but since the commencement of this year several localised epidemics have occurred. In a similar way measles has been widely prevalent in several of the large towns and cities of the kingdom. In Liverpool 472 cases and 70 deaths came under notice between April 1st and 14th, and during the month of March there were 788 cases, of which 107 were fatal. At the last meeting of the Health Committee, Dr. Taylor, the medical officer of health, stated that there was no hospital accommodation, and that for want of this the disease had spread, and many lives had been lost in consequence. In Sunderland there is also an extensive prevalence of the disease, the fatal attacks in the four weeks of the period March 19th to April 9th having been 17, 29, 19, and 26 respectively. And again, in Aberdeen, an epidemic commenced at the close of last year. Thus, 127 cases of measles were reported in the months of November and December, 158 in January, 762 in February, and during March there were no less than 1653, with 138 deaths. Measles is unfortunately a disease against which hardly any precautions are taken by the majority of parents; many being under the false impression that every child must have the disease sooner or later, and therefore the sooner it is over the better. But measles, like small-pox or scarlet fever, is contracted from an antecedent case, and hence it can to a large extent be avoided. Isolation of cases in hospital is not so easily effected as in several of the other infectious fevers, because the disease is so infectious in an early stage when it cannot positively be recognised, and consequently the mischief is often done before prophylactic measures can be adopted. But in a large proportion of cases the spread of the disease could be prevented if parents and school officials only took pains to check the dissemination of the infection. Measles is at times a very fatal disease, and hence it is one that ought to be prevented as far as prevention is possible. Thus, whereas in 1886 the deaths in England and Wales for scarlet fever were 5895, from "fever" 5831, and from small-pox 284, there were no less than 11,576 fatal attacks of measles.

ISLE OF WIGHT SANITARY ADMINISTRATION.

THE Isle of Wight rural district is becoming proverbial for its sanitary difficulties. Another has just arisen. A man who is certainly not a pauper—he being in receipt of his club money—contracts small-pox. No hospital is available except that at the workhouse, and the patient distinctly refuses to allow himself to be isolated there if he is to be regarded as a pauper. Dr. Groves, the medical officer of health, manages, in the sanitary interests of his district, to get him removed there, and the relieving officer is to be asked to make an order for his admission after the admission has been effected. Thus the man is made a pauper whether he likes it or not. The subject in its legal bearings having been discussed by the authority, Dr. Groves was instructed to confer with the clerk and the workhouse medical officer as to the best line of action in future cases. We agree with Dr. Groves that there is nothing to confer about. The workhouse hospital is not intended for such cases; it is illegal so to use it as long as it belongs to the Poor-law authority, and the sanitary authority fails to make any other provision. Until that provision is made there must be constant risk of a deadlock, and such risk cannot be put off by requesting the medical officer of health to take part in a conference with his Poor-law colleague.

GRANULOMA FUNGOIDES.

PROFESSOR KAPOSI, in a paper lately read before the Imperial Medical Society of Vienna, stated that he had seen seven cases of mycosis fungoides (three being males) and of these five had died. He discriminated three clinical types of the affection. In the first the patient suffers at the commencement from a scaly eczema of the trunk, sometimes associated with very severe itching. After from one to three years the spots on the skin become prominent and glistening; an infiltration takes place into these small nodules, which disappear or sometimes break out in other parts. In the course of months or years large fungating tumours appear on healthy skin, attaining the size of a fist, having a bluish-red colour, occasionally dense or very soft and easily compressible. These tumours are mostly seated on the trunk; next on the face, extremities, and scalp. They sometimes disappear with remarkable rapidity; new ones arise in other parts and attain colossal dimensions. Some tumours ulcerate, the ulcers having excavated margins; and after the disease has lasted some years, death takes place from fever, marasmus, or pulmonary or pleural complications

Digitized by Google

In the second type, instead of eczema, there is an eruption of red, urticarial spots, whitish or fawn-coloured in centre, and somewhat dense to the touch. These wheal-like formations persist, extend, and become brown in colour, and the appearance is that of scleroderma or even lepra. All these formations may disappear and occur again, but the spots do not itch; and they ultimately are changed into nodules, which become fungating tumours and ulcerate, taking on the characters and the clinical course of the cases of the first type. The third variety, examples of which have not been seen by Kaposi, consists in the development of the fungoid tumours, without any antecedent process. In speaking of their histology, Kaposi differentiated them from leukæmic tumours, and disputed the discovery of cocci made by Schiff and Hochsinger; he adhered to his previous conclusion that the condition must be regarded as "sarcomatosis cuti." It is not absolutely incurable. Erysipelas is sometimes followed by a complete disappearance of the tumours, and arsenic was to be recommended. This drug was being taken by the patient shown by Prof. Kaposi to the Society—a man thirty-six years of age, who had suffered from the disease since 1875.

SMALL-POX AT PLUMSTEAD.

EVERY epidemic of small-pox is preceded by indications that the disease has a high power of infectivity, and we therefore cannot but regard with some anxiety a localised outbreak of this disease at Plumstead. In the week before last six cases of small-pox were removed to the hospitals of the Metropolitan Asylums Board, and last week a seventh case occurred in the same locality. It is now reported that these patients contracted the disease from a man who had come direct from Port Said, or, rather, from some other persons who in their turn had been infected by him. However this may be, sufficient time has not yet elapsed to show whether the outbreak has terminated, or whether we may expect its still further development. The sanitary authority for Woolwich, the district adjoining Plumstead, are unfortunately without the aid of the services of a medical officer of health, and there is ground for serious apprehension that London may thus be involved in great difficulties for want of the proper machinery for dealing with any immediate extension of small-pox in that locality. We trust the attention of the Local Government Board will be directed at once to this matter, and that the Metropolitan Asylums Board, upon whom the burden of expense of small-pox in London falls, will themselves use their influence with the Woolwich authority for preventing any such calamity as that we indicate.

TREATMENT OF CATARRHAL JAUNDICE.

DR. GLUZINSKI, writing in a Polish journal, states that in cases of catarrhal jaundice he has found excellent results follow the treatment recommended by Krull—viz., the repeated injection into the bowel of large quantities of cold water. This increases the peristaltic action of the intestines, and removes any mechanical obstacle to the flow of bile. Again, as has been shown by Röhrig and Mosler, who injected large quantities of cold water into dogs, the bile is thus rendered both more liquid and more abundant, so that it more easily overcomes any obstruction. At first water at 59° F. is injected into the bowel until the patient complains of a feeling of distension in the abdomen. He is then made to retain it as long as possible. Most patients manage to retain two litres for from a quarter to half an hour. The next day the enema is repeated, but with water about 4° higher. The temperature is again raised on each succeeding day, but when 72° have been reached no further increase is made. The reason of the increase is that the repeated introduction of cold water is apt to irritate the mucous membrane of the bowel. Altogether four or five enemata are sufficient to produce the desired effect. The increase of the biliary secretion may be judged of by the colour of the fæces. Of course, the diet is attended to in order to prevent a recurrence of the affection.

WINDSOR HOUSE DUST.

THE Windsor Town Council have had under consideration a proposal of one of their members to compel householders to provide movable receptacles for house dust, and thus give facilities to the dust collectors to remove this material. This proposal was not adopted, but it is one which the inhabitants of Windsor might readily carry into effect without compulsion. The serious delay which is now caused by the emptying of fixed dustbins must add largely to the cost of collection, and ratepayers would be acting in the interest of their own pockets in adopting a method which would effect an enormous saving in the time of the workpeople employed. There is, moreover, the great additional advantage that this method would prevent the large accumulations of offensive matter, which are now almost inevitable. Although the motion was rejected, it may be hoped it may come before the sanitary authority in some other form. The Town Council are now actively engaged in considering the steps which should be taken for the improvement of the health condition of their district, and certainly so important a subject as the removal of house refuse deserves serious attention.

INTUBATION IN LARYNGEAL DIPHTHERIA.

DR. NORTHRUP (*Medical Record*, Dec. 11th, 1886) advocates the practice of intubation of the larynx originally suggested and practised by Bouchut, and later introduced with greater success by Dr. Joseph O'Dwyer, for the relief of dyspnœa in laryngeal diphtheria. Amongst the advantages claimed for the method, he cites the simplicity of the operation and freedom from shocks, the fact that no objections can be raised to it on the part of friends, and that the subsequent care of the case requires no trained attendant. The inspired air is admitted into the lungs moist and warm; and subsequent tracheotomy is not precluded. One notable objection is the difficulty of swallowing fluids that is experienced, at least at first; and there is a danger lest the false membrane be detached and thrust into the trachea before the tube. The cases in which the method has been practised with relief to laryngeal obstruction amount to 165; and the recoveries amount to 28·5 per cent., a percentage which Dr. Northrup does not think could be shown by tracheotomy, and is the more encouraging in view of the novelty of intubation and the few hands by which it has as yet been practised.

INFECTIOUS DISEASES IN BRUSSELS.

M. DESTRÉE, in presenting the Belgian Academy of Medicine with a chart showing the course of infectious diseases in Brussels during the last six years, remarked that a glance at the chart would show that a very considerable diminution had taken place in all infections but one—viz., diphtheria,—which had been steadily increasing, until in three years the number of cases had been quintupled. He had fancied, as it is thought by some that tetanus has some relation to the keeping of horses, that possibly the occupants of the poultry-yard might in some way cause diphtheria. He therefore injected croupal membranes into pigeons, but always without result. He, however, was much struck, while attending two children in a family for diphtheria, by noticing that all the fowls and pigeons, besides the cat, died during the children's illness.

THE MANAGEMENT OF POST-PARTUM HÆMORRHAGE.

DR. SCHÖNBERG, of the Lying-in Institution in Christiania, writing on post-partum hæmorrhage, states that the number of cases in which this occurred to a serious extent during the years 1876-1884 was 54 out of a total of 2533 labours—i.e., about 2 per cent. of all cases. He appears to have but little faith in ergot for immediate arrest of violent hæmorrhage, either administered internally or as ergotine injections. In the case of women subject to hæmorrhage he advises a course of tonic strengthening treatment during pregnancy. When hæmorrhage occurs the coagula must be expelled by external manipulation, and then he finds that the most advantageous plan of immediately arresting the flow is to close the os uteri by compression. He refers to Hamilton's paper in the *Edinburgh Medical Journal* for 1850, and to Fasbender's similar plans described in 1869, without apparently any knowledge on the author's part of Hamilton's previous work. The Norwegian surgeon introduces the fingers of one hand into the vagina, the tips reaching to the anterior fornix, and pressing the anterior lip of the os backwards. The other hand grasps the uterus externally, anteflecting it while the fingers compress it from behind against the fingers of the other hand, the os being thus mechanically closed. Dr. Schönberg is inclined now to prefer cold to hot injections, notwithstanding the great estimation in which the latter are beginning to be held. He warns obstetricians not to administer irritants too freely, as they set up nausea, and this adds to the condition of collapse. He has, however, latterly been in the habit of giving teaspoonful doses of a concentrated solution of common salt with excellent results.

ACTION OF DRUGS ON GASTRIC MOVEMENTS.

SOME excellent researches are still in process of conduction by Schütz, on the action of some medicaments on the movements of the stomach. Emetine, tartar emetic, apomorphine, strychnine, in a less degree caffeine, veratrine, chloride of barium, nicotine, and pilocarpine in small doses, act as direct excitants of movements of the stomach, which become spontaneous and of abnormal character. Muscarine directly stimulates the terminal ramifications of nerves, in causing generalised contractions of the stomach. Physostigmine, digitaline, scillitine, and helleborine produce an increase in the excitability of the muscular coats in such a fashion that the stomach at a given time is agitated by generalised and prolonged contractions. Actual paralysis of the auto-motor centres has not been observed, but chloral, urethane, morphine, pyrophosphate of zinc, arsenic, as well as nicotine and pilocarpine, in large doses, have caused weakness of the gastric contractions. Paralysis of the terminal branches of the nerves has only been obtained by atropine. Ether and chloroform suppress the excitability of all the innervation apparatus, but only during the time when the stomach is exposed to the direct action of the vapours. During anæsthetic sleep the gastric movements are not influenced.

A SYPHILITIC PLACENTA.

M. DEBRAY described at a recent meeting of the Brussels Anatomical and Pathological Society some peculiar appearances presented by the placenta of a woman who said she had had syphilis a year before her confinement, but who certainly had chancres and a specific roseolous rash at the time. The confinement was at term, and the placenta was removed with some difficulty three hours after the child was born. It was hard and abnormally small. Microscopic examination showed the presence of connective tissue fibres and of numerous plastic elements lying between the connective tissue bundles and forming arterio-sclerotic rings round the vessels.

THE "VICTORIA" DISASTER.

WE regret to see among the list of missing passengers from Newhaven to Dieppe by the ill-fated steamer *Victoria* the name of Mr. F. T. A. O'Meara, L.R.C.P.Lond., M.R.C.S.E., resident accoucheur at King's College Hospital. Mr. O'Meara intended spending a short holiday in Paris, previously to entering on his duties as house-surgeon to Sir J. Lister on May 1st. He entered the medical department of King's College in 1881, and was a prizeman in anatomy surgery, clinical surgery, and obstetric medicine. He also obtained the special prize in Diseases of Women and Children instituted in memory of the late Dr. Tanner. Mr. O'Meara was one of the most intelligent students at King's College, and had gained the affection and regard of all his teachers, fellow-pupils, and colleagues. His loss—for we fear that there is now little hope of his having been saved—is deeply deplored by everyone who knew him.

ALBUMINURIA IN DIABETES.

DR. A. POLLATSCHEK of Carlsbad has published (*Zeitschr. f. Klin. Med.*, xii., 4) some statistical results of the systematic examination of diabetic urine for albumen, with a view to determine whether the occurrence of the latter varies in proportion with the amount of sugar. He found that out of 1187 specimens containing sugar, in amounts varying from traces to as much as 5 per cent., there occurred more or less albumen in 437. The percentage (37) was almost the same, when reckoned on the cases examined in 1885, as on those of 1886, showing a curious uniformity. By grouping the specimens of urine according to their richness in sugar, he shows that there is no constant relation between the amount of albumen and of sugar—the lowest number of albuminurics (29·1 per cent.) occurring in cases of urine with a minimal quantity of sugar, and the highest (43·8 per cent.) in urines having from 2 to 3 per cent. of sugar.

INSPECTORSHIPS OF EXAMINATIONS.

THE Branch Councils in the different divisions of the kingdom are busily engaged in selecting names for recommendation to the General Council in May for appointment as Inspectors of Examinations under the Medical Act of 1886. These appointments should not be mere sinecures, and the profession will expect that they shall be made with much care and impartiality, so that the bodies may all feel that their work is to be ably and impartially judged. The Branch Council for England will meet mainly for this purpose on May 2nd.

COMA FROM ANTHRAX.

THE interesting and in many respects remarkable case which is recorded in another column by Dr. Reilly is perhaps most noteworthy from the insignificant attention given by the patient and his friends to the "boil" at the back of his neck. The state in which the patient was found might have been due to very many causes, but the brief, though clear history, the occupation, and the presence of the malignant pustule, proved sufficient to establish the true nature of the case. It is to be regretted that a necropsy was not allowed.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—M. A. Norbert Michot, the veteran Belgian botanist, at Mons, in his eighty-fifth year. Staff-Surgeon-General Dr. Karl Ritter Heidler von Egeregg of Vienna, in his seventy-seventh year

Digitized by Google

EMPLOYES OF OMNIBUS AND TRAMWAY COMPANIES.

IT is strange that we should still be asked to direct attention to the hard case of the drivers and conductors of omnibus and tramway companies. It really needs no medical knowledge to see the injustice of exacting sixteen hours' work a day from these officials. Such hours give no fair time for rest, or recreation, or home life. It is pitiable to see the men at their principal meals, bolted furtively, often in the car, and before the passengers eager to be off. If the cupidity of shareholders is so great as to blind them to this cruelty, legislation should be invoked. We are opposed to over-legislation. It should not be necessary to invoke the assistance of the Legislature for such a purpose, but if the end cannot be secured otherwise, this step must be taken. The Legislature grants great privileges to tramway and omnibus companies. It has a right to insist that they discharge their duties to the public, and "are merciful to" their men as well as to "their beasts." We have before us a petition to the members of the House of Commons, signed by numerous medical men, urging the reduction of the hours. We heartily support the petition.

ELECTRIC LIGHTING IN THE HOMERTON INFIRMARY.

THE guardians of the Hackney Union have provided their new infirmary at Homerton with electric light, acting on the recommendation of their medical officer, Dr. Miller. Altogether there are 110 incandescent lamps, each of which is of sixteen-candle power; of these many are used for illuminating the corridors, the greater number of the remainder being in the six largest wards, containing in each sleeping accommodation for forty patients. Thus, for the lighting of a ward, the lamps are arranged in groups of three, and four groups are found sufficient, an additional incandescent lamp being provided for night purposes. There is no doubt that electricity, as compared with gas, affords considerable health advantages, and it is probable that the success which has attended the use of this light in the Homerton Infirmary will lead to other institutions following the example which has been set them. The motor power has been provided by a small alteration of the machinery used for pumping water.

ARMY HOSPITAL CORPS IN THE UNITED STATES ARMY.

WE learn from the Washington Army and Navy Register that a law has been passed providing for the organisation of an Army Hospital Corps, and that the Surgeon-General is about to bring it into operation as soon as possible. In the first instance, it will be raised by volunteers from the regiments of the line, but it is probable that afterwards it will be kept up by recruits specially enlisted for this service.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—The veterinary school, which has increased the number of its students threefold during the last ten years, is now raised to the position of a *Hochschule* or university.

Gratz.—Dr. Rudolf R. Jaksch von Wartenhorst has been appointed Extraordinary Professor of the Diseases of Children.

Prague.—Dr. Friederich Ganghofner has been appointed to the Chair of the Diseases of Children in the German University.

AT the annual graduation ceremonial in connexion with the Edinburgh University on the 20th inst., the degree of Doctor of Law was conferred upon Professor Kölliker of Würzburg.

ON May 8th the Federation of the Italian Hygienic Societies will hold its first Congress in Florence. The sittings will last till the 10th and among the proceedings will be a discussion on the new code of public hygiene submitted to the Italian Senate by the Prime Minister, Depretis, and a paper by the Senator, Professor Pacchiotti of Turin, on the "Vaccinazione Anti-rabica" of Pasteur. The great *feste*, of which during the first three weeks of May the Tuscan capital will be the seat, form an attraction of which the promoters of the Congress will avail themselves for enhancing the success of their inaugural meeting.

WE regret to notice the death, on the 3rd inst., of Mr. John Kirkman, at his residence at Brighton. The deceased, who was in his ninety-third year, was for forty-five years (1831 to 1876) superintendent of the Suffolk County Asylum. His name was well known in connexion with the non-restraint system of treatment of the insane.

OUR contemporary the *Echo* kindly gives prominence to the report that one of the few physicians in Brooklyn opposed to vaccination has contracted small-pox from a patient, and that there is little hope of his recovery. We hope he may have a better fate than his folly deserves.

THE President and Council of the Medical Society of London will give a conversazione at the Society's rooms, 11, Chandos-street, Cavendish-square, on Monday, May 2nd. An oration will be previously delivered by Sir William Mac Cormac, F.R.C.S.

DR. W. JULIUS MICKLE was elected some time ago a vice-president of the section of Psychological Medicine and Nervous Diseases at the International Medical Congress.

SIR SPENCER WELLS and Professor BILLROTH have been appointed Honorary Members of the German Surgical Society, which is now in session at Berlin.

A BILL to amend the Acts relative to lunacy has just been issued.

ABSTRACT OF

LECTURES ON MALARIAL FEVERS.[1]

BY W. NORTH, B.A., F.C.S.,
LATE RESEARCH SCHOLAR OF THE GROCERS' COMPANY.

LECTURE I.

THEIR DISTRIBUTION AND THE GENERAL CONDITIONS UNDER WHICH THEY PREVAIL; HISTORY OF THEM IN THE PROVINCE OF ROME.

THE wide distribution of malarial fevers, their disastrous effects upon the population of countries in which they prevail, and the obstacle they constitute to all material progress, are not generally realised; whereas this subject is one which should attract the attention of Governments, inasmuch as these diseases materially increase the cost of administration. We as a nation have had a vast experience of them, and the literature of the subject is enormous, but withal little or nothing has been done towards understanding their etiology, or the precise conditions necessary for their existence or production.

If we examine the malaria chart of the world, we cannot fail to be struck by the gradation of the disease from the Equator to the Poles, and by the characteristics of the countries where it prevails. They are briefly countries where nature has her own way, and swamps, jungle, and

[1] Delivered at the London Institution, April 18th, 1887.

Digitized by Google

virgin forest abound. The map suggests a relation of the disease to temperature and water. If we compare the malaria chart of Europe with a physical map of the Continent, the relation of the disease to low land, abundant water, and hot, moist climate is very evident. Make the same comparison between a physical map of Italy and the map of Senator Torelli, showing the local distribution of the malaria, and the relation of the disease to altitude of the land, to water, and to temperature becomes a certainty. A study of the local distribution and variations of intensity of malarial fevers in the province of Rome shows us that local conditions have a most important bearing on the subject, and are therefore worthy of minute and careful examination; the general conclusions drawn from the consideration of large areas are still found to apply, and we find the disease to be generally most severe on low-lying land—in valleys and marshy districts. An examination of the distribution of the population in the province of Rome shows us that the usual order of things is reversed, and that, whereas in most civilised countries the population is densest in the plains and least dense in the mountains, in the province of Rome exactly the reverse is the case, and we find the mountain population stands to that of the plains in the ratio of sixty-eight to twenty-eight persons per square kilometre. This startling exception to a well-recognised rule leads us to inquire whether political causes have led to the abandonment of the plain and the malaria has simply stepped in and taken possession, or has the malaria itself been the cause of this abandonment; and in either case, when did the causes begin to operate? This is a historical question of the very greatest interest, and also of the very greatest importance to the subject, as tending to show what are the conditions necessary for the development and spread of malarial fevers. There is, however, one very great difficulty in the inquiry, and that is that malaria develops so slowly that, unlike the "black death" or the "sweating sickness," it does not attract the attention of the historian, and thus we are driven to argue its presence or absence and its intensity from the history of individual localities. The one great fact that we have as a starting-point is that in even the later days of the Roman Empire places now absolutely uninhabitable were not only inhabited, but held in high esteem by the Romans as health-resorts, so much so that the whole coast line of the province was covered with their villas and country houses, of which we can see the ruins to-day; and we know from the writings of Pliny and others that these villas were maintained in a state of luxury and magnificence, quite incompatible with the presence of such an enemy to health as malaria. There is some evidence, however, that the Pontine district was not all that could be desired even in those times, and Seneca advises a friend to avoid the neighbourhood of Ardea as not being very healthy. The invasions of the Goths swept away these villas and the high cultivation which surrounded them, the gardens and sacred groves were destroyed, and the population driven to the hills and secure places. Rome itself sank almost to insignificance, the destruction done by the Northern barbarians was never repaired, and the Campagna continued the battle-ground of Saracens, Lombards, rival popes, and barons, rendering a return to the ancient civilisation almost hopeless. In the seventh and eighth centuries we hear of fever, not isolated but wide spread, and of serious attempts by various popes to recolonise and cultivate the desolate country. The so-called Domuscultæ were established, with the double object of military defence and the reclamation of the land, on the site of places which flourished under the empire; but they do not appear to have been successful, or at most, only partially so, and though some of them exist at the present day—e.g., the Isola Farnese, the site of the ancient Etruscan City of Veii,—they are only aggregations of hovels, and so unhealthy that the population desert them in the summer and autumn.

Thus we see that the Campagna was abandoned from causes purely political, and nature was allowed her own way in a country where the unceasing toil of man is required to keep her under control. There can be no doubt that the reckless destruction of trees which has gone on steadily ever since it was begun by the Goths has played a most important part in altering the local conditions and local climate of the country, and in comparatively recent times the reckless cutting of timber in the mountains has caused the streams which rise in them to become uncontrollable and destructive, converting large areas of the lowland into bog and swamp, and rendering cultivation difficult and unprofitable. Our inquiry, therefore, leads to the conclusion that from political causes the local condition of the Campagna have been most profoundly altered, and that *pari passu* malaria has arisen and increased in intensity. A minute examination of the relation of local conditions to the disease will form the subject of the next lecture.

CLASS MORTALITY STATISTICS.

IT is not easy to overrate the importance of the subject of a paper read before the Royal Statistical Society on Tuesday evening last by Mr. Noel A. Humphreys, of the Registrar-General's Department. For elucidating the true value of local rates of mortality we have urban and rural death-rates, we have death-rates at different age periods, we have death-rates from different causes, and we have the death-rates of male adults engaged in different occupations. Till recently, however, we have known very little of the rates of mortality prevailing in the different classes of society. The object of Mr. Humphreys' paper was to discuss existing mortality statistics throwing light upon this important subject, and especially to examine critically the full bearing of the statistics issued during the last few years by Dr. Grimshaw, the Registrar-General of Ireland, dealing with the mortality prevailing in various social classes of the population of Dublin.

On account of the marked variations of the age proportions of the various social classes of the population, the only thoroughly satisfactory method for comparing the mortality statistics of such classes is by the construction of life tables, and the first part of the paper is devoted to the examination of the principal English life tables, and especially of those which throw any light upon the special subject of the paper. It is pointed out, in the first place, that the various English life tables based upon the general population show a marked and steady increase in the mean duration of life in recent years. The Carlisle table gives 39 years as the mean duration of life, whereas Dr. Farr's table, based upon the mortality of the 17 years 1838-54, gives 41 years; a table based upon the mortality of the five years 1876-80 gives 44 years; and the mortality of the next five years, 1881-5, shows a still further extension of life. Dr. Farr's healthy district table (based upon the mortality statistics of sixty-three registration districts in which the mean death-rate in the ten years 1841-50 did not exceed 17 per 1000) gives 49 years as the mean duration of life. Very few life tables based upon class mortality statistics exist. The most important examples of the class life tables referred to by Mr. Humphreys are Bailey's and Day's Peerage Tables, Ansell's Tables of Upper Classes, and Hodgson's Clergy Tables. Although not, correctly speaking, class tables, the Experience Tables of the Institute of Actuaries, and of the American Life Offices, throw valuable light upon the mortality of insured, and therefore of selected healthy lives, belonging, for the most part, to the middle and upper classes. Ansell's Upper Class Table gives a mean duration of life of 53 years—an increase of four years upon that by the Healthy District Table. Unfortunately, it appears that no life table of the working classes exists, although the mortality statistics issued by Dr. Grimshaw for the General Service Class in Dublin are such as to suggest that the mean duration of life in this class can scarcely, if at all, exceed that by Dr. Farr's Liverpool table—namely, 26 years.

An examination of these several life tables shows that the mean duration of life is mainly controlled by the rate of mortality in childhood. In all the life tables based upon the mortality statistics of the general population, the mortality during infancy and early childhood is so great that the expectation of life is greater at ten years of age than it is at birth. By Dr. Farr's English Life Table, for instance, the expectation at birth is 41 years, while at age 10 it is 47 years; and even by the Healthy District Table it is 49 years at birth and 51 years at age 10. Ansell's Upper Class Table, however, has such a comparatively low rate of child mortality that the expectation of life is 53 years at birth, which declines to 52 years at age 10. The variations in the annual death-rate of children under five years of age by the different

Digitized by Google

tables is very noteworthy; it is 65·7 per 1000 by the English Life Table (Dr. Farr's No. 3), and 39·4 by the Healthy District Table, while by Ansell's Upper Class Table it does not exceed 28·2. Dr. Grimshaw's statistics show a rate of only 22·0 among children of the professional and independent class in Dublin during the three years ending 1885.

Subsequently to childhood the greater vitality of the middle and upper classes, compared with that of the general population, is only somewhat less marked than it is under five years of age.

The most recent statistics of occupational mortality, constructed by Dr. Ogle, and issued by the Registrar-General, although not coming within the scope of class mortality statistics, as they only deal with adult males, throw, at any rate, a side-light upon the subject. Taking the mortality of all males aged 25 to 65 years as 1000, the relative mortality of males engaged in different occupations, after due correction for age differences, is shown by Dr. Ogle to range from 556 for "Clergyman, Priest, Minister," 599 for "Gardener, Nurseryman," 631 for "Farmer, Grazier," and 701 for "Labourer in Agricultural Counties"; to 1839 for "Miner (Cornwall)," 1879 for "Costermonger, Hawker, Street Seller," 2090 for "General Labourer (London)," and 2205 for "Inn, Hotel Servant." Many of these differences are evidently due far more to the influences and risks of occupation than to the mere influence of class; and it seems probable, however, that the wide difference between the mortality of labourers in agricultural counties and labourers in London must be mainly due to difference of housing and sanitary surrounding, as both classes probably suffer about equally from poverty, hard work, and hard living.

As information of the variations of child mortality in the various classes is essential to a full appreciation of the lesson to be learned from class mortality statistics, Dr. Grimshaw's statistics, notwithstanding defects, in great measure unavoidable in such an experiment, are especially valuable. They demand attention, in the first place, to the marked variations in the age distribution of the population in different classes. For instance, 1000 of Dr. Grimshaw's professional and independent class contain only 75 children under five years of age, instead of 121 in the artisan class. Then the proportion per 1000 of persons aged upwards of sixty years is 158 in the professional and independent class and only 63 in the artisan class. Mr. Humphreys shows that given identical rates of mortality in each of Dr. Grimshaw's four classes, at each age period, the death-rate at all ages would, owing alone to the differences of age distribution, range from 19·5 in the middle class to 25·2 in the professional class. The actual mortality in the classes differs, however, very widely in the other direction. If 1000 be taken to represent the mortality that would occur in each class if English life-table rates prevailed, the mortality in Dublin in the three years 1883-4-5, in Dr. Grimshaw's four classes, corrected for age differences, was equal to 632 in the professional and independent class, 1093 in the artisan class, 1333 in the middle class, and 1659 in the general service class.

The variations in the death-rates at different age periods in the several classes is especially striking. Thus, the mean annual mortality under five years is just five times as great in the general service class as in the professional and independent class. The difference at the next age-period, 5 to 20 years, is almost as great, and in each of the three age-periods of adult life the rates of mortality are more than twice as high in the general service class as in the professional and independent class.

The rates of mortality from various causes of death show fully as wide differences as do the death-rates at different ages. For instance, mortality from measles is nearly ten times as great in the general service class as in the professional and independent class; from whooping-cough, more than four times as great; from scarlet fever, more than twice as great; from diarrhœa, nearly three times as great; from typhus, nearly five times as great; from phthisis, more than four times as great; from lung diseases, more than three times as great; from convulsions, nearly thirteen times as great; and from violence, more than five times as great in the general service class as in the professional and independent class.

In concluding his analysis and discussion of Dr. Grimshaw's figures, Mr. Humphreys urges the necessity for further investigation in the same direction, and expresses the hope that medical officers of health and others may follow Dr. Grimshaw's lead and improve upon his statistics. Calling special attention to the near approach of the death-rates among the clergy and labourers in agricultural counties, he urges a stronger faith in the possibility of reducing the present wide range between the death-rates of the upper and of the working classes. Comparing the rates of labourers in agricultural counties and of labourers in London, it is suggested that this is due not so much to difference of poverty and hardship, but to the unhealthy homes and impure air from which the London labourer mainly suffers. The marked reduction in the working-class mortality, especially of infants, in the Peabody buildings, points, at any rate, to one effective method of bringing the mortality of the working classes within sanitary control. These and other similar facts indicate further possible reductions in the now rapidly declining English death-rate, the possible extent of which it is not easy to estimate.

THE LUNACY ACTS AMENDMENT BILL.

A MEETING of the Council of the Poor-Law Medical Officers' Association, to which workhouse medical officers had been invited, was held at their rooms, 3, Bolt-court, Fleet-street, on April 14th. Prior to commencing the business of the evening, a unanimous feeling of regret was expressed at the continued absence from the chair of Dr. Joseph Rogers, owing to severe illness. Clause 14, subsections 5 and 6, of the Lunacy Acts Amendment Bill was then discussed, and it was considered by the Council and visitors present that the alteration of the clause by the Parliamentary Bills Committee of the British Medical Association fully met the requirements of the case, and the secretary was requested to write to the chairman of that committee to tender the co-operation of the Association, in what manner it may be deemed advisable, with a view to having the obnoxious clause amended in the Commons. It was also suggested that the word *shall* be substituted for *may* in Clause 19, line 4, which refers to the payment of fees by the guardians under orders of the justices. The opinion of the secretary of the Lunacy Commissioners as to the great value of the certifying of pauper lunatics by the workhouse medical officer was considered important in reference to the amendments proposed.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chailey Rural District.—The general survey of sanitary districts carried out by the Local Government Board was extended to this area, and Mr. Graveley reports that as a consequence special attention was devoted to the drainage of several villages, to the abatement of nuisances from the keeping of animals and from filth accumulations, and to the enforcement of bye-laws. The current systematic inspections were also carried out during the year, and the dairies and milkshops were placed under supervision. The annual death-rate for 1886 was 15 per 1000. Six deaths occurred from typhoid fever, the disease originating in an encampment of people travelling in vans.

Coventry Urban District.—Owing to the prevalence of measles in the city, and its extension on such a rapid scale that hospital isolation could not check it, the closing of elementary schools became a necessity. Dr. Fenton explains that this step involved to the school managers and teachers a loss of £110, and hence that it is a serious one to adopt. It has generally been assumed that any loss of grant accruing from actual closure of schools would be made good if the closure were effected under the regulations of the education code; and it is certain that this should be so, otherwise a great hindrance is placed in the way of checking the spread of disease. In eight weeks ending with the second week of October, 570 fresh attacks took place, the schools being open. School closure was then resorted to, and the new attacks fell in three weeks from 76 to 10. They were then reopened,

Digitized by Google

th an increase to 23 and then to 42 a week. The fresh break was found to be associated with one single school, d this being closed a second time, the disease subsided. nongst the other matters dealt with in Dr. Fenton's port is an account of the use made of the excellent hos-al for infectious diseases. As already implied, it could t be much used for measles, but 111 patients were mitted, 84 of these suffering from scarlet fever. Formerly ık followed on the sending of children home direct from e hospital, but under the arrangements now in force the mmunication of infection by this means has virtually en put an end to. Excellent work was also done during ıe year as to disinfection, 3140 articles and 91 houses being ubmitted to that process.

Halifax Urban District.—With a population of 78,287, ıe death-rate for 1886 was 22·2 per 1000. The borough ospital received 48 cases of infectious disease, 18 of these eing typhoid fever; there were also 16 deaths from diph-neria in the borough, but no cases of this disease were eceived into the hospital. Amongst the matters needing eform to which Dr. Ainley refers is the scavenging of the oads, which is evidently badly carried out, causing needless ffensiveness to the public, and especially to the tradesmen n the principal lines of traffic. The report of the sanitary nspector shows an excellent amount of work, carried out with efficiency and regularity.

Lytham Urban District.—During 1886 there was an in-rease in the number of cases of enteric fever, most of the ttacks being associated with obvious faults in sanitary arrangements. Good work is steadily in progress in the matter of the removal of excreta and refuse from the vicinity of dwellings; and many of the old-fashioned privies, which cause such abominable nuisance, have been done away with. Complaint as to sewer ventilators has been found to be occasioned by fault in the tributary sewers. Both these and house drains joining them, if faulty, are likely to cause nuisance in an otherwise good system of sewers. Deducting the sad loss of life which occurred in the seven lifeboatmen who were drowned during the year, the death-rate was 16·3 per 1000, the birth-rate being 26. *Preston Port* is also in Dr. Eason's district, and as to it he states that he has had no occasion to inspect any vessel on account of infectious disease. We hope we may assume that inspection is not limited to such instances. The main value of port sanitary inspection is to secure a gradual improvement in the sanitary circumstances of the vessels and crews entering the several ports, and we regard it of even more importance to make a regular chronicle of the results of such preventive work than to record action taken on the occurrence of such diseases as would largely be prevented by systematic sanitary inspection.

Sunderland Port District—Considerable vigilance was necessary in this port during the past year owing to the recurrence of cholera in Europe. The number of vessels clearing from the port was 6982, and of these 2223 were inspected for sanitary purposes. There were 37 written notices served in consequence, all of which were complied with; and 289 verbal notices were also met in the same way. Of the British ships inspected, 15·9 per cent. were in an insanitary condition, compared with 10·2 per cent. of all foreign ships examined. This reflection upon British ships applies in the main to those engaged in the coasting trade, of which 5437 cleared from Sunderland, and the defects complained of relate not so much to structural defects as to great and inexcusable carelessness. The Danish and Dutch cargo ships entering the port are typical examples of cleanliness, and this notwithstanding the fact that they are usually built of wood, and that many are old. Mr. Harris has pointed this out in the hope of inducing a greater amount of care amongst the masters of British cargo ships.

Watford Urban District.—This town, which has at intervals suffered, a good deal from diphtheria, had some recurrence of the disease last year, but both diphtheria and other infectious diseases were isolated in the sanitary hospital. At one time the sewers were credited with mischief; they are now flushed every fortnight, and a disused chimney shaft is to be brought into requisition for the ventilation of one portion of the system. Unfortunately, houses are being built where they cannot at present be sewered, and hence cesspools are resorted to. It is to be hoped that modern bye-laws control the construction of such receptacles, thus keeping them at a distance from dwellings and water-supplies, and preventing any escape either by soakage or overflow. The death-rate during 1886 was 18 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5806 births and 3696 deaths were registered during the week ending April 16th. The annual rate of mortality in these towns, which had been 23·5, 21·6, and 20·5 per 1000 in the preceding three weeks, was last week 20·9. During the first quarter of this year the death-rate in these towns averaged 20·0 per 1000, and was 2·2 below the mean rate in the corresponding quarters of the ten years 1877-86. The lowest rates in these towns last week were 10·6 in Brighton, 14·5 in Halifax, 17·0 in Cardiff, and 17·8 in Derby. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the nine preceding weeks from 340 to 502, further rose last week to 510; they included 266 from measles, 115 from whooping-cough, 45 from scarlet fever, 32 from diphtheria, 26 from diarrhœa, 24 from "fever" (principally enteric), and only 2 from small-pox. These zymotic diseases caused the lowest death-rates last week in Birkenhead and Derby; and the highest rates in Norwich, Hull, Sunderland, Manchester, and Huddersfield. The greatest mortality from measles occurred in Manchester, Sunderland, Norwich, and Huddersfield; whooping-cough in Oldham, Plymouth, and Blackburn; and scarlet fever in Bristol. The 32 deaths from diphtheria in the twenty-eight towns included 21 in London, 2 in Bristol, and 2 in Liverpool. Small-pox caused 1 death in Greater London and 1 in Blackburn, but not one in any of the twenty-six other large provincial towns. Seven cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; no new case was admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 509, 417, and 363 in the preceding three weeks, rose again to 363 last week, and were 107 below the corrected average. The causes of 76, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Salford, Newcastle-upon-Tyne, Portsmouth, Preston, Norwich, Plymouth, and Derby. The largest proportions of uncertified deaths were registered in Liverpool, Huddersfield, and Brighton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the preceding four weeks from 26·2 to 22·9 per 1000, rose again to 23·7 in the week ending April 16th; this rate exceeded, however, by 2·8 the mean rate in the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·0 in Perth and 15·8 in Leith, to 27·3 in Glasgow and 33·7 in Aberdeen. The 593 deaths in the eight towns last week showed an increase of 20 upon the number in the previous week, and included 36 which were referred to whooping-cough, 28 to measles, 10 to scarlet fever, 7 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 4 to diphtheria, and not one to small-pox; in all, 91 deaths resulted from these principal zymotic diseases, against 127, 111, and 102 in the previous three weeks. These 91 deaths were equal to an annual rate of 2·6 per 1000, which was 0·3 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 31 and 33 in the preceding two weeks, further rose to 36 last week, and included 15 in Glasgow, 9 in Edinburgh, and 6 in Aberdeen. The deaths from measles, on the other hand, which had been 58 and 43 in the previous two weeks, further declined last week to 28, of which 14 occurred in Aberdeen and 10 in Glasgow. The 10 fatal cases of scarlet fever, including 4 in Edinburgh, 3 in Glasgow, and 3 in Dundee, exceeded those in the previous week by 4. Of the 7 deaths attributed to diarrhœa, showing a considerable decline from the numbers in recent weeks, 4 occurred in Glasgow and 3 in Edinburgh. The 6 and 4 deaths referred respectively to "fever" and diphtheria differed but slightly from recent weekly numbers; 2 from "fever and 3 from diphtheria were returned in Glasgow. The deaths from acute diseases of the respiratory organs in the eight towns, which had declined in the preceding four weeks, from 152 to 110, rose again last week to 126, and exceeded the number in the corresponding week of

Digitized by Google

last year by 4. The causes of 55, or 9 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 31·3 and 30·0 per 1000 in the preceding two weeks, rose to 34·1 in the week ending April 16th. During the first quarter of this year the death-rate in the city averaged 30·9 per 1000, the mean rate during the same period being but 17·8 in London and 19·4 in Edinburgh. The 231 deaths in Dublin last week showed an increae of 28 upon the number returned in the preceding week; they included 7 which were referred to measles, 6 to "fever" (typhus, enteric, or simple), 4 to scarlet fever, 4 to whooping-cough, 1 to diarrhœa, and not one either to small-pox or diphtheria. Thus 22 deaths resulted from these principal zymotic diseases, against 18 and 15 in the preceding two weeks; they were equal to an annual rate of 3·3 per 1000, the rates from the same diseases being 2·2 in London and 3·6 in Edinburgh. The fatal cases of measles exceeded the number returned in any previous week of this year, and the deaths from "fever," scarlet fever, and whooping-cough showed an increase upon those in the previous week. The deaths both of infants and of elderly persons also showed an increase upon the numbers in the previous week. Eight inquest cases and 9 deaths from violence were registered; and 78, or a third, of the deaths occurred in public institutions. The causes of 37, or 16 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Deputy Surgeon-General W. Cattell has been appointed Principal Medical Officer at Cork.

Deputy Surgeon-General Sir J. A. Hanbury, K.C.B., embarked on the 21st inst. for Gibraltar, to take over the duties of Principal Medical Officer.

Surgeon General Simpson, Sanitary Commissioner with the Government of India and head of the Indian Medical Service in Bengal, comes home shortly in anticipation of his retirement from the service next autumn.

INDIA OFFICE.—The Queen has approved of the following admissions to the Indian Medical Service:—To be Surgeons (dated September 30th, 1886): Bengal—Robert Joseph Macnamara, M.D., Herbert Wilson Pilgrim, George Brooke French, Francis Wyville Thomson, Edwin Harold Brown, Charles Norman Bensley, Selby Herriot Henderson, David Wilson Scotland, Charles Robert Mortimer Green, James Henderson Sellick, Edward Christian Hare, Frank Cecil Clarkson, John Gregory Jordan, John Digby Marsh Swinburne, Herbert Mackinlay Morris, Allan Rupert Postance Russell, James Morwood, M.D., and Edmund Alexander William Hall. Madras—Gilbert Capel Hall, Richard Henderson Castor, Frederick Geo. Maidment, Marie Joseph Toby Joinville Blancard, and Ignatius Purcell Doyle. Bombay—Blenman Buhot Grayfoot and Thomas Edward Dyson.

The following Officers, whose admission to the Indian Medical Service (Bengal) has already been notified, should have been placed in the following order:—William Grant Thorold, Patrick Hehir, Lionel John Pisani, Basanta Kumar Basu, Narendra Prasanna Sinha, Wm. Rice Edwards, Charles Mactaggart, John Fenton Evans, George James Hamilton Bell, Joseph Thomas Daly, Henry Fooks, Ernest Hudson, Arthur Cecil Deare, Arthur William Dawson, William Henry Banner Robinson, and Henry Anderson Sheppard.

ADMIRALTY.—Staff Surgeon Robert George Bird has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet (dated April 11th, 1887).

The following appointments have been made:—Surgeon Thomas Nunan, to the *Wasp* (to date from 21st inst.); Mr. James P. Smith, to be Surgeon and Agent at Ullapool; and Mr. T. E. Mellerick to be Surgeon and Agent at Waterville.

RIFLE VOLUNTEERS.—5th Durham: Surgeon and Honorary Surgeon-Major P. Brown resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement (dated April 16th, 1887). 1st Shropshire: George Hopton, Gent., to be Acting Surgeon (dated April 16th, 1887).

Correspondence.

"Audi alteram partem."

PUNCTURE BY TROCAR OF THE TYMPANITIC ABDOMEN IN PUERPERAL CASES.

To the Editors of THE LANCET.

SIRS,—May I be allowed to correct an error into which Dr. W. O. Priestley has inadvertently fallen, through my fault, in his note on the above subject in your issue of April 9th. After remarking that Major Franklin had said that he recollected some suggestion of mine concerning tapping in such cases, he adds, "and Dr. Hicks tells me that though he had suggested it as applicable under certain circumstances, he had not himself employed it." At the time Dr. Priestley spoke to me on this subject I did not remember that the last of four published cases which I had myself done was after a case of Cæsarean section. This case occurred in 1867. The report was read before the Obstetrical Society of London in 1868, and published in vol. x., 1869. In one of your contemporaries of that year the matter was discussed by others as well as myself, cases being narrated, and questions of priority raised showing that a number of quite independent practitioners had been relieving tympany by trocar; but it appeared that it had been employed in France earlier than here. It was afterwards discussed in the Clinical Society and published in its Transactions. I believe that with care this operation might be had recourse to more frequently than hitherto in cases of severe distension, where the depression caused by the generally accompanying peritonitis is much intensified by the pressure on the sympathetic system. In any case, I can answer for an enormous relief to the sufferings of the patient, and in some cessation of the constipation resulting from the over-distension of the bowels by the gaseous contents.

I am, Sirs, yours truly,

J. BRAXTON HICKS.

George-street, Hanover-square, April 18th, 1887.

To the Editors of THE LANCET.

SIRS,—In 1875, while house-physician at St. Bartholomew's, a case of scirrhus of the rectum was under my care. The patient suffered acutely from distension due to flatus. I therefore asked the house-surgeon to puncture the colon. His refusal may be taken as indicating that this little operation was not fashionable in those days. Hence this short illustrative note. I at once inserted a fine exploring trocar. While the gas was issuing from the cannula, the patient loudly proclaimed the relief attending its exit. One may fairly presume that the puerperal cases are not unfavourable to the performance of this simple but effectual operation; but surely the necessity for its employment seldom occurs.

I am, Sirs, yours faithfully,

April 20th, 1887. T. H. SAWTELL, M.D. Lond.

THE MARGARET-STREET INFIRMARY APPOINTMENTS.

To the Editors of THE LANCET.

SIRS,—Will you allow me, as one of those who have accepted vacant posts in the above institution, to submit, with all respect, that in your implied censure (in the annotation this week) of any who are not "avowed homœopathists" for accepting such vacancies you seem to take up an untenable position? The presence of homœopathists on the staff is either prejudicial to the interests of the patients or it is not. If the former, then the action of medical men—not avowed homœopathists—in joining the staff deserves your approbation, since by diluting homœopathic influence and diminishing homœopathic practice, they would tend, *ex hypothesi*, to augment the advantages and lessen the risks of the patients. If, on the other hand, homœopathists do *not* imperil the welfare of the patients, there is no justification for your condemnation of those who choose to exercise the same charity as they. You may hold that I have not stated the real point at issue, and maintain that it is professional honour which is at stake, in which case if applied to me you would exalt the importance of boycotting [illegible]

Digitized by Google

mbers of the profession above the needs of those for ose benefit the charity exists. Doctors are made for man, ; man for doctors. Supposing every member of the pro- sion who is not a homœopathist, avowed or otherwise, l abstained from applying for the vacant post, one of > things must have happened—either the vacancies uld have been filled by homœopathists or not filled all. I have dealt above with the question of a mœopathic staff as affecting the patients; and as ards the other alternative of the posts being left ant, it comes to this: that the leading journal of a so- led noble profession—a profession which is supposed embody some of the grandest instincts of humanity >y implication advocates that patients should be left stitute of advice until certain offending brothers, guilty the unpardonable sin of differing from the majority pecting therapeutic doctrine, shall be excommunicated. e interests of the poor are to be sacrificed in order that ofessional prejudice may be satisfied. For myself, I do t profess kinship with either "'path." I believe it my alienable right to pursue any path (in my efforts to relieve e sick) which may, in my judgment, offer the fairest omise of success; and I think members of a charitable—a ogressive, liberal, and scientific—profession, whose views e notoriously in a chronic state of change, should nerously accord to others the same liberty of opinion ey claim for themselves. Of this I feel assured: the iblic—and particularly the poor who may avail themselves this charity—well know how to appreciate the moral urage of those who, at the risk of being branded as mœopathists, and boycotted accordingly, consider it an nour to serve the needy, though it be in the Margaret- reet Infirmary. Even if exposed to contamination therein, e shall have the satisfaction of continuing, with enlarged portunities, our quest for what is still undetermined— e truth about therapeutics.

I am, Sirs, yours obediently,

JOHN BECKETT.

Brook-street, Grosvenor-square, W., April 18th, 1887.

To the Editors of THE LANCET.

SIRS,—Permit me to state, in reply to the, no doubt unin- ntional, *suggestio falsi* contained in your paragraph anent ie Margaret-street Infirmary, that I am *not* a homœopath, r any other kind of "'path," either "avowed" or covert; nd in order that there may be no misunderstanding, I mean hat I do not adopt the dogma of *similia similibus curantur*, r any other dogma, as my rule of practice, but aim as nearly s may be at a rational empiricism, ignoring no source of nformation claiming to be backed by clinical experience. Iy opinion on matters therapeutic cannot be more lucidly tated than you have yourselves expressed it in your leading rticle of to-day: "The ordinary practitioner differs from he homœopathic in being free to use any drug which he nows to be of use in the case, and that in any quantity xperience shows to be best." I accord *in toto* with the ositive side of this statement, though as regards the egative side I have yet to learn that homœopathic prac- itioners repudiate that freedom. Having, I need scarcely ay, expected some antagonistic remarks on the matter, I was prepared to make the above statement, but being fully ware of the vast amount of prejudice which exists, I had letermined to keep silence on the ethical side of the uestion. However, the moderation of your leading rticle, when dealing with the subject of homœopathy, nduces me—whether judiciously or not remains to be een—to depart from that determination, and to offer a ew remarks. Considering your admission that homœo- athy *has* done some service to medicine; considering he fact that I am frankly compelled to admit the debt I owe (I will not say to homœopathy, but at any rate) o individual homœopathic practitioners for the intro- luction to certain drugs, particularly in my own special lepartment of practice (e.g., the tinctures of apis mellifica and of æsculus hippocastanum), as well as for the extended phere of utility of others (e.g., bichromate of potash), of all of which I shall by-and-by have something to say, founded not upon any dogma but upon clinical experi- ence; and considering that for the survival of one or two principles of therapeutic action—e.g., the value of minute subdivision in developing therapeutic power in comparatively inert substances (of which a dark example remains to us in the hydrargyrum c. cretâ of the B.P.) —medicine is, I believe, mainly indebted to homœopaths, I fail to see the logical consistency of maintaining in public relations a position of exclusiveness, especially on the surgical side, which is being, to my absolute knowledge, tacitly shelved every day in private practice by numbers of my professional brethren holding positions on the staff of hospitals connected with the great medical schools. Remembering, as I do, the outcry and prejudice aroused by the utterances of Dr. Bristowe and Mr. Jonathan Hutchinson at the British Medical Association's meeting at Ryde, I do not anticipate that these remarks will have any weight with those from whom I have the misfortune to differ. But perhaps they may serve, at any rate, to show that in medical as in other politics it is possible for two parties to arrive at diametrically opposite conclusions in perfect sincerity and good faith. With apologies for occupying your valuable space to such an extent with personal and therefore uninteresting matter,

I remain, yours faithfully,

Welbeck-street, W., April 16th, 1887. KENNETH MILLICAN.

SCOTTISH DIPLOMAS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 2nd we have your leader and Mr. Berkeley Hill's remarks as to Scotch and Irish qualifications, which are blackballed, in comparison with the "London diplomas" of L.R.C.P. and M.R.C.S., a subject not new to your paper, especially the "Scotch" part of the question. It is, I think, a great pity that gentlemen in the position of Mr. Berkeley Hill in the profession should deal in such statements, supported by him by no argument, good, bad, or indifferent. If you or he can find holes in the Scotch system of examination, in its results, in its methods or the degree of competency it insists on, in the breadth and completeness of the test for any Scotch diploma at all, why do you not do so? Why does not Mr. Berkeley Hill do so? Any person who likes to observe or inquire into the truth of this matter will simply find that all such statements are the result of a warped judgment—I might justly add, in very many cases of jealousy. The English public respects Scotch diplomas. That is a truth that will stand probing, and the success of men holding them as an integral part of the medical profession is notorious and above cavil. And why? The reason is not far to seek if Englishmen could put aside their "green spectacles," and I will state it briefly. The "evolution" of the English medical man is only now, in 1887, reaching a point that it had reached in Scotland centuries ago. In medical education and examination the Scotch system always did, and does yet, involve a complete curriculum, a complete examination, and a complete qualification. In England, as is well known, such has not been and is not the case yet, or until very recently. It is to become law in June, 1887; and I say it fearlessly that England is only now attaining a point of efficiency in matters of medical qualification that was attained in Scotland 250 years ago. This is true of medical education and examination. It is likewise true of the general education of the respective nations of Scotland and England. Scotland has led the van in advance by hundreds of years. I will prove what I say if you or your readers choose to contravert it; meantime, I must not encroach on your valuable space further.

I am, Sirs, yours faithfully,

Birmingham, April 16th, 1887. JAMES GILROY, L.F.P.S.GLAS.

A DOCTOR'S INCOME.

To the Editors of THE LANCET.

SIRS,—Various articles have been appearing in THE LANCET lately in regard to the position of the profession and the pressure on the general practitioners produced by the depression of trade, by the competition of hospitals, and so on. As we general practitioners have no voice but through the medical press, may I ask space for a rather long letter? The differences which separate consulting physicians and surgeons on the one hand, and family doctors on the other, are as wide and deep as those between barrister and solicitor. The general public do not know this. They imagine that any clever ambitious lad who can find the funds to squeeze into the profession somehow may rise to be Sir Somebody Something with an income of £15,000 a

Digitized by Google

year. If they knew how hopelessly improbable this is, and, further, knew what the actual financial prospects of a lad entering the profession (to be a family doctor) are, I cannot believe such numbers would continue to crowd in. I have made several calculations to enable me to arrive at a correct estimate of a general practitioner's income, which I submit. The first method I adopted was to add up the value of all the practices advertised for sale in various numbers of THE LANCET. The mean of 175 practices was £625 a year, which I consider as the average income of the family doctor. From this I deducted the working expenses. Taking into consideration surgery expenses, drugs, horses, carriages, assistants, dispensers, &c., I reckoned these as ranging from £25 a year to £500. I allowed three small practices to two medium and one large, and this gave the mean working expenses as £150 a year. Again, I reckoned the average cost of a medical education at £700. I have further estimated the cost of starting in practice, whether by making a practice or buying one (much the same as regards expense, I take it), at £1000. This gives £1700 capital sunk. On this I have reckoned 5 per cent. interest—i.e., £85 a year and £35 insurance premium to safeguard the capital, or £120 in all. My sum stands thus:—

Average gross income of a family doctor ...		£625
Average working expenses of do.....	£150	£270
Interest on capital sunk.....	£120	
Mean net income		£355

Further, it being usually necessary to live in an important thoroughfare, we pay higher rent, and therefore rates, than most men with incomes of £355 a year. We pay income-tax on the £120 a year, which enables us to recover our lost capital. Out of the remaining £355 we have to save for sickness and old age, and yet we pay income-tax on the whole. The pensioned classes pay no income-tax on the sums that Government virtually lays by for them. Finally, while carriages are a necessity in almost all practices over £500 a year, we pay tax on them on the ground that they are luxuries! If all this is considered, we can hardly estimate a doctor's income at much over £300 a year. This is the income of those who *have* practices, but there are hundreds of men who for lack of capital or other causes have no practice. They are assistants at salaries ranging from, say, £50 to £150 a year and their board; or they are ship's surgeons at a salary of about £80 or £90 a year and their food whilst on board; or they are house-surgeons or physicians at salaries ranging from nothing to £100 a year and their board. If all these men were taken into consideration, I feel sure the net income of a general practitioner would be found to range somewhere near £200 a year. I will now consider this question from another point of view to check my first results. Of the 175 practices I examined for the purposes of this letter, seventy-three, or nearly one-half, were purely country practices, and the mean gross income of these was only £442 a year, and therefore the net income probably not much over £200 a year.

Again, I will take a third point of view. I know of a practitioner who travels four miles for a charge of 1*s.* a visit, one-quarter of the cab fare that would be charged him if he hired a public conveyance. This does not sound profitable, but there is worse to come. Almost every country doctor has a benefit club included in his practice, for attending the members of which he receives from 4*s.* to 5*s.* per head per annum. I find that the mean sickness per head per annum, according to the experience of the Foresters, is 1·917 week, or say two weeks, per annum per head—equivalent, say, if the work is honestly done, to six visits per head per annum. This gives us from 8*d.* to 10*d.* per visit, including medicine. The parish doctor descends still lower. A vacancy was advertised recently in THE LANCET. A parish doctor was wanted for a district having an area of twenty-four square miles. I presume this doctor was not expected to *walk* his rounds? In that particular county one in every twenty-six of the population is a pauper. Allowing the visits to average seven per head, instead of six for the members of friendly societies (as women and children are included as well as men), the doctor will receive about 7*d.* per visit, out of which he has to find medicine and carriage expenses. Lower still are the "sixpenny" dispensaries of London. Lastly, every medical man does some work for nothing at all. With such rates of remuneration, how can the profession prosper? Do you wonder now that you hear daily of medical men dying utterly penniless? Remember that a doctor works on Sundays as well as weekdays, by night as well as by day. It is more difficult for him to get a holiday than for almost anyone. Besides his hard work he has many special perils—perils of epidemics, perils of post-mortems, perils of exhaustion from want of adequate rest or sleep, perils of exposure at night when ill, and nowadays we must add perils of worry from vexatious actions or false accusations. Such is the state of affairs what is the remedy?

I am, Sirs, yours faithfully,

April, 1887. E. PAGET THURSTAN, M.D.

GASEOUS RECTAL INJECTIONS IN CONSUMPTION.

To the Editors of THE LANCET.

SIRS,—Dr. Burney Yeo's able Lecture on Gaseous Rectal Injections in Consumption is a welcome contribution on a subject which is exciting much notice, and, along with a paper which appeared in one of your medical contemporaries last December, will doubtless serve to bring Bergeon's method still further under the attention of practitioners in this country. After making some trial of it, I wrote to Mr. W. H. Perkin, F.R.S., regarding tests for discovering chemically the vapour of bisulphide of carbon in the breath, in order to find out if it was eliminated unchanged, and, in replying, he cautioned me on the injurious effects the bisulphide sometimes produces on the health of those working with it. That such cautions were not altogether needless was soon proved by the symptoms which overtook one of my patients: great irritability and moroseness, and a "tipsy feeling," which so distinctly amounted to incapacity for work or clear thinking as to be noticeable by others. My object is not to deter practitioners from the use of bisulphide of carbon vapour, but to advise that care should be exercised about the dose, and particularly about the frequency of its administration, for its elimination from the system appears to me much slower than that of sulphuretted hydrogen. As the symptoms did not come on till after many days of its use, I am inclined to trace them to accumulated arrears of imperfect elimination. Those who care to inquire further into these symptoms may refer to "Blyth's Poisons, their Effects and Detection."

I have now abandoned the use of the bisulphide, and adopted the sulphuretted vapour from the Eaux Bonnes water. Dr. Burney Yeo properly remarks on the inconvenience of obtaining this water. Perhaps Harrogate might be an available source, for the old sulphur well there contains 5 3 cubic inches of sulphuretted hydrogen per gallon, as against 1½ cubic inches per gallon in the water at Bonnes.

I am, Sirs, your obedient servant,

Ventnor, April 19th, 1887. JAMES M. WILLIAMSON.

"SURVIVANCE AFTER GUNSHOT AND OTHER WOUNDS OF THE HEART."

To the Editors of THE LANCET.

SIRS,—Should the following account of a case of wound of the heart, with which I have been just favoured by my old friend and correspondent Dr. James Martin of Portlaw, approve itself to your better judgment, I will thank you much to give it the benefit of your great publicity. It shows, at least, great faith in the curative virtues of bleeding, and may, so far, interest those *laudatores temporis acti* of our art who, if there be still any such amongst us, regret the disfavour into which that once much-admired remedy has fallen. But of this anon. Writing under date April 3rd instant, my kind informant says: "Reading your paper in THE LANCET to-day recalls to my memory a case in which I was interested so far back as 1827, while I was serving my second year's apprenticeship in the Queen's County Infirmary. It stands thus: 'A man who was going home from the town (Maryborough) attacked another (who carried with him a bayonet for his protection) with a loaded whip. The attack was repelled by a thrust of the bayonet, and this thrust floored the man, who fell down and became at once unconscious. He remained in this state during the fifty-three hours he survived, and meanwhile ninety-six ounces

Digitized by Google

of blood were taken from him, at intervals, during this time. Notwithstanding this deprivation, however, he did not die from loss of blood. On the contrary, the young man—who was just on the point of qualifying—who remained in constant attendance on him, maintained to his dying day that this patient would have lived had the surgeon in charge permitted him—the young attendant—to take more blood from him. On examination of the remains there was only one mark of injury on them—viz., a small triangular wound two inches below the edge of the ribs on the left side. The weapon seems to have traversed the stomach and penetrated the diaphragm, the pericardium, and the wall of the left ventricle. The pericardium contained a large fibrinous clot, which had undergone some organisation, but the fibrinous element predominated in it." It is, in either case, not easy to see how phlebotomy, even *usque ad deliquium*, could have prolonged this poor fellow's life. Yet such was one of his quasi-qualified attendant's belief; and this belief affords of itself another illustration—were any such wanted—of the fact that nothing takes so much killing as an old superstition.

I am, Sirs, your obedient servant,

Auriol-road, W., April 10th, 1887. WM. CURRAN.

To the Editors of THE LANCET.

SIRS,—With reference to the paper on the above subject by Brigade Surgeon Curran, in THE LANCET of the 9th inst., the following brief abstract of a "gunshot wound case of the heart" may throw a ray of light on the subject, and be deemed of sufficient interest to publish.

About ten years back, whilst I held medical charge of the R.A. division at Allahabad, North West Provinces, Bengal, a gunner of the division deliberately shot a sergeant of his own battery one night. The poor victim, an excellent non-commissioned officer, highly thought of, in some way incurred the ill-will of the murderer, a good-for-nothing, morose, ill-tempered man, of intemperate habits; and as the sergeant, accompanied by a comrade, reached the top of the stone staircase leading to his own quarters, a little after gunfire—i.e., nine o'clock at night,—the bullet struck him as he turned towards the left hand side to go to his own room. It was given in evidence, I believe, by the non-commissioned officer who was by his side, and had ascended the stairs in his company, as well as from information given me by others who were near enough to hear, that the poor fellow, when shot, turned round about a quarter-circle towards the spot whence the shot was fired—a doorway to the left and behind the stairway, fifteen to twenty feet only away—advanced a few steps towards the murderer, whom he was able to clearly recognise by the barrack-room and passage lamp, saying, as he did so, "Ah! is that you, ——?" or somewhat similar words, showing he saw clearly who it was that had fired the shot, and then reeled and fell to the ground. Of course, I am speaking from memory, but the unusual occurrence made a deep impression on my mind. Moreover, the whole facts of the case were fully recorded in the official reports and trial in the High Court. The post-mortem examination was also noted by me in the case-book at the time. Suffice it now to say that I found the bullet had struck the left ribs—fourth or fifth, as well as my memory recalls—external to the nipple line, then passed through the anterior portion of lung overlying the heart in that position, had passed backwards through the left ventricle, inflicting two ragged wounds, then through the root of the right lung, smashing two ribs on the right side, and was found in several large and small pieces scattered about the right axilla, and under the scapula of the same side. The weapon used was a Snider carbine, calibre 0·577, with full service charge of powder, and fired not over twenty feet away; yet, in spite of the terrible wound inflicted on the heart, there was evidence to prove that not only was the murdered man able to turn partly round, but also to walk a few paces, speak in a clear voice, and to clearly recognise his assailant.

Two facts may be considered interesting as bearing out Brigade Surgeon Curran's views regarding the murder of the native Kadir near Peshawur, and of his being probably able to speak and recognise his assailant after receiving the fatal wounds in the heart, and it should be remembered that a Snider bullet is over half an inch (0·577) in diameter, and usually inflicts a terrific wound, as I have seen a case where a similar bullet striking a man in the forehead tore out nearly the whole of the occipital bone in its exit. The case may also be interesting from a medico-legal point of view.—I am, Sirs, yours truly,

April 12th, 1887. J. E. FISHBOURNE, M.D., F.R.C.S.I.

To the Editors of THE LANCET.

SIRS,—In connexion with Brigade-Surgeon Curran's interesting paper on the above subject, allow me to draw attention to the following passage from General Gordon's Journals at Khartoum, page 17:—"One man received a wound in the chest; he lived eleven days, and died. The doctor found a bullet lodged in the centre of his heart, in wall of ventricle. The doctor has this heart in spirits. It was a ball weighing the same as our Martini-Henry bullet." Accompanying the paragraph is a drawing showing a section of the heart and the embedded bullet, thus proving that the General had seen and sketched the specimen. The record, apart from its pathological interest, is a striking instance of the catholic sympathies of the hero of Khartoum.

I am, Sirs, yours faithfully,

Brighton, April 7th, 1887. JAMES TURTON, M.R.C.S.

THE TREATMENT OF PLACENTA PRÆVIA.

To the Editors of THE LANCET.

SIRS,—I have read with interest Dr. Braxton Hicks' letter in your issue of the 9th inst., and fully endorse his supposition, "that no particular method of managing placenta prævia can claim being *the treatment*." Also the rule, "deliver as early as possible after the recognition that the placenta is about or athwart the mouth of the womb," with the addition, "do not leave the patient till she is delivered." In many cases, however, where there is a sharp loss after detachment of the placenta as far as the finger can reach and it is not possible to turn and plug the os by the leg or breech, I have found the air-ball pessary simply invaluable.

Some four or five years since I was called to a primipara—the smallest woman I ever delivered,—who had been in pain for some hours, and was losing freely. The history was that of placenta prævia. With the greatest difficulty I reached the os, which barely admitted the tip of my finger, and, finding the diagnosis correct, ruptured the membranes and detached as much of the placenta as possible. My patient suffered from a weak heart, precluding the use of chloroform; her abdomen was so unusually tender that any handling was impossible; the vagina barely admitted two fingers, and sharp hæmorrhage was going on. An air-ball pessary (I always carry one in my bag) was applied, which at once stopped the bleeding and so stimulated the os by its pressure that regular pains began almost immediately; the vagina at the same time being dilated by the artificial wedge. Twice the ball was withdrawn and reapplied—after the finger had been swept around the os,—being kept as large as the patient could bear it, so assisting dilatation that although the forceps were applied as soon as the os was sufficiently open, the perineum was uninjured and the recovery perfect. Since that time, in every case of placenta prævia, save one, I have adopted this plan, with the same success.

The exception mentioned was that of a woman who had been attended by a medical man from a cheap dispensary, and who had calmly watched her flooding herself pulseless—the condition in which I found her—from Friday morning until 11 P.M. on Monday, when the husband begged me to save his wife, if possible. Another medical man had been previously fetched, but he declined to undertake the case, and promptly retired from the scene. I found the room like a slaughter-house; the child's right hand and funis protruding from the vulva, the arm fortunately plugging the os, and the patient requesting that she might be allowed to die in peace without further torture. After administering eggs and whisky, the only available nourishment, I detached the placenta as far as was necessary, turned, delivered, and was able to leave the house within the hour. The patient recovered without any bad symptoms.

I am, Sirs, yours truly,

T. WALKER COFFIN, F.R.C.S. Ed.

Haverstock-hill, N.W., April 11th, 1887.

CURRELL'S CASE.

To the Editors of THE LANCET.

SIRS,—Having presented a numerously signed medical memorial to the Home Office praying that an examination should be made of Currell previously to allowing the law to take its course, as suggested in your columns, I give a few facts relating to the case. The Home Secretary responded to the prayer of the petitioners, but, so far as I can judge from the account in the newspapers, the examination was directed to his *present* state, not his past, which was the point raised by the petitioners. Since his execution, I have had Currell's verbatim confession placed before me. The opinion I entertain remains as before. It is confirmed by the statement. Currell says: "I have been for a long time accustomed to taking drugs, and have had frequent bouts of drunkenness. One of these bouts commenced about a week before the murder. During the whole of the succeeding week I had very few sensible moments, and, if I were to have my liberty for it, I have not the slightest recollection of how I spent the whole of that week." This was part of a confession written on Sunday night, within a few hours of his execution. It accounts for the "irrational state of mind" into which Mr. Justice Grantham says he must have been at the time, and justifies any petition that was forwarded asking for a medical examination. His apparent indignation at being thought irresponsible is made much of in the papers as evidence of his sanity. It is a well-known fact that many persons would rather go to gaol as rational beings than be liberated on the ground of unsoundness of mind. This fact also strengthens my argument. The whole case from beginning to end was one of moral insanity. Whether caused by drugs, alcohol, or not, the case remains the same, and aggravated by strong hereditary taint of mental disorder.

I am, Sirs, yours obediently,

L FORBES WINSLOW, M.B.CANTAB., D.C.L.OXON.

Hammersmith, April 20th, 1887.

"PASTEUR'S METHODS."

To the Editors of THE LANCET.

SIRS,—In his letter under the above heading in your issue of the 9th inst., Mr. Vincent Richards expresses his anxiety that the dangers of Pasteur's prophylactic treatment for hydrophobia should be recognised, but he seems somewhat to ignore the much greater dangers of untreated bites from rabid animals. It is largely a question of statistics. Mr. Richards' reasoning about the necessity of the prophylactic inoculation being begun on the day of the bite rests on a misapprehension on his part of the facts of the case, for as regards length of incubation, there is all the difference between accidental bites and inoculation by trephining.

The published statistics up to the end of last year are as follows:—

—	No. of cases treated.	Deaths from all causes.	Mortality.
Paris	2730	45	Under 2 per cent.
Odessa	325	12	" 4 "
St. Petersburg ...	118	1	" 1 "
Moscow	112	2	" 2 "
Vienna	96	0	—
Warsaw	84	0	—
Naples	48	0	—
Samara	47	2	Under 5 per cent.
	3560	62	Under 2 per cent.

During the present year several more deaths have occurred (some, very possibly, from the treatment), but they do not appear to have exceeded 12 or 15, bringing the total deaths from all causes among these 3560 persons to something less than 80, and giving a mortality not exceeding 2¼ per cent. In contrast with this we must place the average rate of mortality after bites from rabid animals, and this is probably about 16 per cent. So that it would appear that for every death occurring after Pasteur's treatment there would probably have been seven deaths had that treatment not been adopted. I do not maintain that this result is final and certain, but I think the evidence for it should not be lost sight of by those who are so keenly alive to the dangers of Pasteur's system of treatment.

I am, Sirs, yours &c.,

April 12th, 1887. R. J. P. S.

THE INTERNATIONAL STATISTICAL CONGRESS.

(*From our Correspondent.*)

UPWARDS of fifty representatives of statistical research met on Tuesday, the 12th inst. in the hall of the Ministry of Finance, under the presidency of Sir Rawson W. Rawson, to inaugurate the first International Statistical Congress. There had been other meetings of a similar kind, in which the statisticians of all countries assembled to compare their work—meetings composed of official delegates of different European states, and first set on foot in 1853 by M. Quetelet. But international jealousies had marred their efficiency—notably, on occasion of their permanent seat having been proposed to be fixed in Paris, when the German delegates intimated that in that case they either would not or could not attend, and so at the jubilee meeting of the Statistical Society of London in 1885 it was resolved to make the International Congresses independent of all Governments, representing simply the best science of each country, though, of course, quite open to receive whatever co-operation or support these Governments would vouchsafe.

Italy showed herself, as she always does, full of hospitality towards the visitors who had come to assist at the august occasion, and her Minister of Agriculture and Commerce, Signor Grimaldi, opened the proceedings by a brief address in French, in which, after indicating the value of statistics as a basis for legislation throughout the whole civil order, hygiene included, he extended to the Congress the welcome of the Italian Government.

Sir Rawson W. Rawson followed, also in French, of which he is a master, and gave a lucid narrative of the progress of statistical organisations, of the circumstances in which this first unofficial or purely scientific International Statistical Congress was being held in Rome, and of the rules and regulations which had been devised and approved for the "International Statistical Institute," as it is henceforth to be called.

The institute is an international association having for its object the development of the progress of administrative and scientific statistics: 1. By introducing, as far as possible, uniformity in the methods of compiling and abstracting statistical returns, and by adopting it in the compilation of statistical publications, with a view to a comparison of the results obtained in different countries. 2. By inviting the attention of Governments to the various problems capable of solution by statistical observation, and by applying for information on those subjects which have not hitherto received adequate statistical treatment. 3. By preparing international publications as a means of bringing into communication the statisticians of various countries. 4. By endeavouring, through the medium of publications, and, if practicable, by public instruction and other suitable means, to foster the general appreciation of statistical science, and to stimulate the interest of Governments and individuals in the study of social phenomena.

The sitting of Wednesday, the 13th, was exceptionally interesting. Professor Neumann Spallart, of Vienna, read a memoir on "Social Statistics," in which he expounded with characteristic clearness the method devised by himself of estimating with the greatest possible precision the social and economic state of a country in a given period, and of arriving at a numerical and approximately exact expression of the conditions, economic, social, and moral, of a nation. Restricting his data to Western Europe and the United States of America, he explained the "graphic system" whereby he proposes to determine the production of [illegible] country for each year. On the same system he determines the mean of emigration, of crime, of disease, by which may be called a barometer of sociologic and [illegible] phenomena. He has convinced himself that he can [illegible] at approximate sociological forecasts, and with [illegible] accuracy as is displayed in those [illegible]. An animated and most interesting [illegible]

which the method was criticised from the point of view of the economist, the statesman, and the hygienist, and a detailed reply on the part of Professor Neumann Spallart brought the discussion to a close. The official report cannot fail to interest all scientific readers—not least the medical.

Of much more direct professional interest was the memoir of Dr. Léon Vacher, member of the French Corps Législatif and president of the Statistical Society of Paris. His subject was the "Diminution of Mortality and the Augmentation of the Mean Duration of Life in Europe." Having established, from official returns drawn from the various statistical bureaux of European States, that mortality is lessening and that longevity is increasing in the more civilised countries, he passed in review the causes which have produced, or which have contributed to produce, this result; first, among the latter—that is, the contributory—causes being, in his view, so far as France is concerned, the French Revolution, from the economic ameliorations it brought in its train and the more effective organisation of State medicine. He also drew confirmation of his doctrine from the sanitary condition of the young Italian kingdom, and dwelt on the immense progress made in a few years in public hygiene throughout the peninsula as highly creditable to nineteenth century sanitation. Turning to Rome, he said that from the hygienic point of view the city was scarcely recognisable as the same centre of population which existed before 1870, a fact which redounded highly to the praise of the Italian Government. Dr. Vacher's paper, which was heard with much attention, and emerged from the subsequent discussion with its main positions unshaken, will form not the least interesting of the publications of the Congress shortly to appear, with their author's revision, under the editorship of the Commendatore Ellena, secretary to the Ministry of Commerce and Agriculture.

The subject, so well introduced by Dr. Vacher, was followed up by a communication from the Cavaliere Bodio, of the statistical bureau of Rome, to whose unwearied and well-inspired activity the success of the Congress is largely due. This was a table, with a diagram on the "Lexis" model, for calculating and comparing the mean mortality at the different periods of life and in different countries. This the Cavaliere explained in a lucid exposition, and set forth many interesting facts on the ratios of births and deaths, on the malaria, and on the other sources of disease prevalent in Italy. The discussion was continued by Professor Levasseur and others, and a really instructive report was compiled for Signor Ellena's editorship.

Friday's sitting began with a report drawn up by Sir Rawson W. Rawson and Signor Maffeo Pantaleoni, on the "Means of preparing in each country a catalogue of publications, official and non-official, giving exact information on every one of the more important branches of statistics"; after which, at 8 P.M., Dr. Ole Jacob Broch, sometime Minister of State in Norway, and correspondent of the Institute of France, read a paper on the "Consumption in Europe of Nervine Excitants: the Alcohols, Coffee, Tea, Cocoa, Sugar, and Tobacco." Beginning with a retrospect of the introduction into Europe of alcoholic beverages, which have made immense strides from the early years of the eighteenth century to our own days, he showed by numerical data that the countries in which the consumption of these is greatest are Denmark, Belgium, Russia, and Germany; next come England and France. Italy is one of those in which the consumption is least. He maintained that in Norway the consumption of spirits is decreasing, owing to legislative provisions restricting their sale and also to the temperance societies. He then treated of the production and consumption of coffee, tea, and cocoa, showing that the production of coffee in the latter half of this century has doubled, while the countries that consume most of it are the Netherlands, Belgium, Norway, and Russia. Tea is mostly consumed in England, after her coming the Netherlands, Denmark, and Russia; while the countries in which the consumption of cocoa is greatest are Spain, France, and Switzerland. As in the case of the alcohols, so in that of these beverages, he supported his conclusions by financial returns. Passing next to the general production and consumption of sugar and the rise of prices, he noted that the production of Barbadoes sugar has probably attained its maximum. England, Ireland, and France are the greatest consumers of sugar—from 1880 to 1884 from two to three million tons of it having been used. Its consumption, indeed, is on the increase everywhere. Finally he demonstrated that the production and consumption of tobacco amounts to 500 millions of chilogrammes yearly, its consumption being greatest in the United States of America, in the Netherlands, in Denmark, England, Germany, Sweden, Norway, and France. The state revenue from the consumption of tobacco exceeds a milliard of francs, France deriving the most from it and Great Britain next. An interesting and animated discussion on Dr. Broch's essay ensued, in which the Swiss and German delegates took the chief part.

The remainder of the proceedings included no other topic bearing directly or remotely on medicine.

Saturday's sittings were the last, and, among the incidents of the forenoon, was the invitation of M. Inama Sternegg, of Vienna, to the members of the institute to attend the great Hygienic and Demographic Congress in the Austrian capital in September next.

M. Körösi, in the afternoon, read a paper in which he proposed to make international statistics uniform by the adoption of a table containing the following heads:—1. Statistics of houses and of the families occupying them. 2. Statistics of families according to the number of their members. 3. Agglomeration of the population and classification of cities. 4. Classification of the population by sexes. 5. Classification by age. 6. Bachelors, married men, widowers, divorced husbands, according to age. 7. Nationalities. 8. Religious creeds. 9. Unlettered (*analfabeti*), according to age. 10. Place of birth. 11. Distinction of groups under 2000 inhabitants in the country and above 2000 in the town. 12. Physical and moral disease.

A conversation then ensued on the next time and place of meeting, and it was finally resolved to convene the Congress for September, 1889, in Paris, under the presidency of Sir Rawson W. Rawson.

The Ministers of Commerce and Finance, Signors Grimaldi and Magliani, then congratulated the members of the International Statistical Institute on the success of their first Congress, and expressed their satisfaction at Rome having been made its seat. Sir R. W. Rawson gracefully returned thanks, and the Congress thereafter dissolved.

The proceedings were lightened by many acts of hospitality on the part of the Italian Government towards the members—admission to the first representation in Rome of Verdi's *Otello*, a banquet given by his Majesty King Humbert in the Quirinal Palace, and an excursion to the Falls of Terni (rendered famous by the description in "Childe Harold," and now utilised for the manufacture of steel plates for ironclads) being among the entertainments provided for the "congressisti."

Rome, April 17th.

THE RIVIERA IN 1887.

THE EARTHQUAKE.—MONTREUX.—LES AVANTS.

(By our Roving Correspondent.)

(Concluded from p. 803.)

RATHER severe strictures have been made in the French press and elsewhere *à propos* of the very general exodus which took place after the earthquake. Those who have made them have given no reasons to show that the move away was, under the circumstances, unwise or impolitic. Never, probably, in the history of the world, has a similar catastrophe occurred among a population so essentially mobile. At Nice and Monaco the thousands of visitors were practically all pleasure-seekers, and a large proportion of them were excursionists, furnished with return tickets, who had come for the Carnival. The hotels, as I have said, are for the most part not strongly built, and, although visitors may tolerate these structures for the sake of the southern sun, it is not to be wondered at that the prevalence of earthquakes should breed some degree of distrust in the builder's handiwork. Again, it must be remembered that at Nice and Mentone, where houses had been *lézardé* in all directions, the lighting of fires had become dangerous, and had, indeed, been forbidden, so that even invalids found it difficult to get a cup of warm milk or beef-tea. At Mentone the supply of good bread ran short, and the reflection could not but arise that in all probability a dislocation of water, gas, and sewer pipes had taken place, a state of things which involves consequences upon which we need not dilate. There was no question, be it remembered, of

Digitized by Google

persons running from the post of duty, but merely of pleasure-seekers abandoning a spot which had become unpleasant. Again, the effect of the earthquake upon the majority was, the writer believes, as follows. The first shock caused surprise, but not fear; and had there been no subsequent shock there would have been no genuine desire to leave the district. When the second shock came some fifteen minutes later, the sense of distrust was aroused; but the third shock at 8 o'clock, which forcibly brought home to everyone the possibility of continuance, was, we believe, mainly operative in causing the exodus by bringing to every thoughtful person the reflexion as to the number of similar shocks which his or her particular hotel was capable of withstanding. The incessant discussions of the subject became almost intolerable, and after a time was enough to unhinge the nerves of the most phlegmatic, and it was on this account mainly that a speedy removal from the immediate scene of the disaster became desirable, especially for persons who were not strong, and who found it difficult to sleep.

The fact cannot be too strongly insisted on that a considerable proportion of the houses along the Riviera have been very severely strained by the earthquake, and that substantial repairs will be needed in order to make them withstand even a slight recurrence of the shocks. The withdrawal of the visitors has given the inhabitants leisure to undertake the work of reparation; and we trust, in the interests of those who year after year repair to this region, that the task will be undertaken with the serious intent of rendering the houses as strong as human ingenuity can make them. Great praise is due to the authorities of the Paris-Lyons-Mediterranée Railway Company for the manner in which they met the unusual strain put upon their traffic regulations. Happily, no damage was done by the earthquake to the lines, and for a fortnight subsequently to Feb. 23rd a very large number of special trains were run, and all of them were absolutely full. Not only did no serious accident occur, but we did not hear that even a stray handbag or portmanteau was lost.

The loss of one is the gain of another. The serious misfortune which befel many of the places along the Riviera had the result of sending an influx of visitors to other places. Hotels in outlying districts which had been nearly empty suddenly enjoyed a great accession of business, and it was literally true that for a time every hotel along the Riviera westward of Nice and as far as Marseilles was absolutely crammed. The effect was felt further than this. Visitors driven from the Riviera were naturally afraid to return to northern climates at the end of February, and, accordingly, the tide set in towards Pau, Biarritz, Arcachon, and the Pyrenees, towards Meran in the Tyrol, towards the sheltered spots along the northern shore of the Lake of Geneva and our own southern coasts, which are at their best in the early days of spring.

Being desirous, after the earthquake, to get away from the incessant bustle and disquiet which the catastrophe naturally caused in all crowded places, I moved to an hotel not far from Cannes, which, although a fine house in a good situation, was, I had heard, almost empty. This I found to be true, and, on my arrival, I became the co-pensionnaire of some ten other people who were the only occupants of a magnificent building standing in a situation at once lovely and healthful. The chief reason of the emptiness of this fine house was revealed at dinner-time, when a veritable Barmecides' feast was served with most admirable solemnity to guests who unwillingly followed that golden theory of dietetics that "it is good to rise from table with an appetite." This hardly merits to be mentioned were it not for the fact that, in my opinion, much of the hotel feeding along the Riviera is second-rate. Of late years hotel prices have risen considerably, and with the rise of price there has not been, to say the least, a corresponding rise in the quality of the accommodation. The worst food which invalids, to say nothing of healthy persons, can take is second-rate French cookery. The finest climate in the world will not compensate for a diet of disguised garbage, and many of the *plats* which are handed at *tables-d'hôte* merit this description. The characteristic of second-rate French cookery (and there is very little that is first-rate out of Paris) is the absence of refinement or simplicity. When, for instance, a sole is handed to you smothered in a concoction of colour, strong herbs, and grease, you will not be wrong in assuming that this mode of cooking has been adopted as a means of smothering qualities which might prove less appetising than the mess which has been added by the *chef*. Fish has a delicate flavour of its own, but this fact is seldom appreciated, and there is also an utter ignorance of the fact that the varieties of flesh and vegetables have any characteristic flavour. The conceited *chef* who works under a miserly *maître d'hôtel* soon comes to think that any tough rags in the way of meat will serve as a vehicle for sauce, and hence it not unfrequently comes about that, after breakfasting on sour bread and chicory and lunching on rubbish, the person with a delicate stomach succumbs before dinner-time, and as he cannot eat the dinner he has paid for, but requires to be nourished on "extras" in his own room, the shortsighted proprietor, who only looks to the profit of the hour, fails to appreciate how serious is his responsibility in this important matter. I cannot too strongly urge upon delicate persons who are obliged to winter abroad the necessity of great care in the selections of hotels. The points which demand attention are: (1) aspect as regards sun and wind; (2) construction as regards safety, tranquillity, and health; (3) the size and ventilation of the public rooms; (4) the quality of the food, inclusive of the wine. Every hotel proprietor will do well to return to the good old custom of placing a sound "ordinaire" upon the table. All meals ought to be *vin compris*, and in writing for terms this point ought to be insisted upon. It is impossible for persons to pay five or six francs per meal for wine, and it is intolerable that they should be expected to drink so-called "claret" which has been opened for days and kept in a cupboard. The very small quantity of wine which is consumed nowadays ought to be included in the price paid for the meal. This custom still obtains in all localities which have not been ruined by English and Americans. Let those who have had experience in the latter houses only try the experiment by going to dinner at such a house as the "Hôtel des Bains" at La Condamine, and they will find that a modest four francs suffices to get a well-cooked wholesome meal, *vin compris*. To "please the English," hotel proprietors have been led into much lavish expenditure in the matter of gaudy decorations, carpets, and hangings. These things cost money, and, if they are to be kept clean, necessitate a great increase in the staff of servants. Carpets and hangings do not materially increase the warmth of a building, but they do undoubtedly harbour filth of all kinds and, if they be not kept clean, become a constant menace to health. These things are wholly unsuited for a southern climate, and they are especially unsuited for a climate where the mistral upon occasions raises clouds of dust. A glistening floor of tiles or polished wood or marble, kept bright by a daily sweep, is far better suited to the "sunny south" than are thick carpets into which the dust sinks and is forgotten, and in due time, under the influence of the sun, becomes instinct with life. Less hangings and better food must be the order of the day in southern hotels which are used as convalescent hospitals. After a sojourn of ten days near Cannes, and after the rush of persons going west had somewhat subsided, I moved away to the district at the north-east end of the Lake of Geneva, which has the reputation of enjoying a mild climate and of being a pleasant spot in which to spend the spring. Vevey, Clarens, and Montreux, which are almost continuous with each other, are situated along the northern shore of the Lake of Geneva. They face due south, and are protected by a range of high hills from the north, the protection from this source being more absolute at Montreux than elsewhere. The Lake of Geneva is about 400 miles due south of London, so that the sun is more powerful there than here. Again, it is about 1000 feet above sea level, so that the consequent rarefaction of the air increases the effect of the sun's rays upon persons exposed to them. Further, the mildness of the situation is said to be largely influenced by the proximity of the lake, and it is contended that this huge volume of water tends to equalise and increase the mean temperature of the district. There can be no doubt whatever that this district, especially Montreux, is well sheltered, but it must not be supposed that the warmth to be experienced there is at all equal to that which is felt along the Riviera. After spending the winter in the Riviera, and when the sun here gets too strong and a need is felt for a more bracing situation, then a move to the Montreux district is very desirable. One of the chief drawbacks to the latter place is the liability to fog, owing to the proximity of the lake. Arriving at Montreux towards the middle of March, I found every hotel in the place quite

Digitized by Google

full, owing to the influx of visitors from the south. I accordingly made for the hotel at Les Avants, which is some 2000 feet above Montreux, and consequently 3000 feet above sea-level. It was about 3 o'clock in the afternoon that I started from Montreux railway station. Montreux was enveloped in fog, which completely hid the sun and obscured all objects at the distance of a few yards. The ascent to Les Avants is rapid and continuous, and the result was that in a quarter of an hour the fog was almost all below me, and in half an hour I was in brilliant sunshine. The drive to Les Avants occupied about an hour and a half, and the road is excellent. Arrived there, I found the hotel situated in the centre of an amphitheatre of hills, which surround it on all sides except the south. The protection from wind is absolute, the sun exposure perfect. It was very interesting to notice how complete had been the change of climate in rising from Montreux to Les Avants. I had left a cold fog and draughty streets to rise into the brilliant warmth of the afternoon sun in a cloudless sky, and with scarcely a breath of wind. This absence of wind was very noticeable during the whole fortnight which I passed at Les Avants. From the point of view that all experience is useful, I may say that I had the good fortune to experience some very severe weather at Les Avants. The weather at the time of my arrival was mild and spring-like, the snow was all gone from the lower fields, and the crocuses were showing their many-coloured tips in abundance. Nearly forty hours' continuous snow, however, at the middle of March (at the same time that the severe snow-fall occurred in England and through Europe generally) changed the aspect of affairs. The snow lay nearly three feet thick, and gigantic icic'es hung from the overlapping eaves. It was very interesting to observe how comparatively little inconvenience was suffered from this very heavy fall of snow—a fall considerably heavier, probably, than any I have ever witnessed. The snow plough was sent down the road as a matter of course to a point to which another snow plough came from Montreux or some neighbouring village, and thus our communications were kept open without any difficulty whatever. The post came with all its proverbial regularity; and even the laundress (who lived at Montreux) was not hindered in her routine journeys for a single hour. Owing to the absence of wind there were no drifts, and by the early use of the plough the snow was not allowed to deprive us of our fresh air and exercise. The snow was, in fact, a source of great enjoyment, for it enabled us to return to the pleasures of winter. The little sleighs called *luges* were soon in requisition, and we had soon an opportunity of seeing how the eight kilometres of winding road which intervene between Les Avants and Montreux may be accomplished *en luge* in some half-hour. From the experience of a few days only it was made evident that mid-winter in these high regions must be very enjoyable, and certainly few things more exhilarating can be imagined than to scud along over the glittering snow at the rate of ten or fifteen miles an hour through the crisp air, illumined by a brilliant sun in a cloudless sky. When you have reached Montreux, the old adage "To go there, I trow, is easy enow, but how about getting back?" is apt to haunt the mind; there is nothing for it, however, but to shoulder your *luge* and get back by the short cut, which can be done in about an hour and a half; and a wonderful chest expander is this return journey. The hotel at Les Avants is good, and the proprietor does all in his power to make his guests comfortable. The writer went for three days and stopped fifteen.

BEQUESTS AND DONATIONS.—Among the numerous bequests of the late Mr. William Brough Phillimore, Hyde-park-gardens, are the following: To the Ventnor Hospital for Consumption, £200; St. George's Hospital, London, £200; Consumption Hospital, Brompton, £300; Royal Hospital for Incurables, Putney, £200; St. Mary's Hospital, Paddington, £200; Middlesex Hospital, £200; University College Hospital, £200; and King's College Hospital, £200.—The secretary of the Leicester and Leicestershire Provident Dispensary has received a legacy of £100 from the executors of the late Mr. G. A. Robinson.—The secretary of the Bristol Eye Hospital has received a legacy of £100 from the executor of the late Mrs. Peace of Devizes.—Mr. W. H. Williamson, of Bradford, has forwarded £50 to the Bradford Infirmary and £25 to the Children's Hospital, to be applied as the Boards of Management of these institutions think fit.

MANCHESTER.

(From our own Correspondent.)

OPEN SPACES.

THE praiseworthy attempts of the Open Spaces Committee to in some degree remedy the neglect in past years to provide open spaces in the centres of our crowded districts are resulting in a very fair amount of success. On the 9th inst. a plot of about one acre and a half, situate in Ardwick, was formally opened by the Mayoress, and there was a large attendance. The society has spent nearly £2000 in laying this plot out and providing swings &c. They will retain charge of it for the next two years, and then hand it over to the Corporation, through whom the land has been acquired. In the neighbouring suburb of Withington, a piece of land some thirteen acres in extent has been given by Lord Egerton, "to be used as a public recreation ground, open to the public free for ever." One of our members of Parliament, Mr. Houldsworth, in conjunction with Sir John Lubbock, is endeavouring to promote a piece of legislation having for its object the granting greater facilities to acquire land &c. for these purposes, making applicable to the whole country the provisions of the Metropolitan Open Spaces Acts.

ROYAL INFIRMARY.

It sounds at first rather strange to hear of donations coming from Germany to our local hospitals. The Royal Infirmary has just received £500 from a lady residing at Frankfort-on-the-Maine, in memory of her late husband, Mr. G. Kissell, who some years ago was in business here.

THE EPIDEMIC OF SCARLATINA

still continues, and shows but little abatement. Dr. Buckley medical officer of health for Crumpsall, in his report for 1886, just issued, referring to the disease in his township, speaks of his inability to get any reasonable proportion of patients suffering from scarlatina removed to the Monsall Fever Hospital. He advocates the provision of smaller hospitals situate nearer the patient's home, and where the friends would feel more in touch with their children than when they are two or three miles away. The Salford Corporation will soon have the question of hospital accommodation for infectious cases to face, they having recently sold their present building to the North-Western Railway Company, and the infirmary authorities have since refused to take more cases from Salford to their fever hospital at Monsall than they do under existing arrangements.

THE SHIP CANAL.

A large model of the proposed ship canal, lately exhibited here prior to going to the Jubilee Exhibition, brings before one's mind very forcibly the danger there may be of there being very little better than an open sewer in the docks and stagnant portions, unless stringent measures are adopted to render less polluted the Irwell and the Medlock, which rivers will form the chief feeders to the canal.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

At the annual meeting of this Association, Dr. Tatham, officer of health for Salford, was elected chairman for the ensuing year, and gave an address in which he took rather a pessimist view of the present position of State medicine, and of those who devoted themselves to its service. He, however, showed that there was ground for hope that in the not far distant future a change for the better would be inaugurated, and the status of officer of health improved.

ECONOMIC DIETARY.

The subject of the need for some systematic organisation for providing poor children of school age with cheap meals was recently discussed at a conference held at the Vegetarian Restaurant, Fountain-street. Mr. Sargant, of Birmingham, gave details of what had been done in that town, and it was pretty clearly shown that, without pauperising the people, nutritious meals, necessarily based largely on a vegetarian dietary, could be provided at a cost of less than one penny per meal; but that, from lack of knowledge among the poorer classes, it was impossible for them to obtain the result in their own homes. Hence the need of some organisation.

DUBLIN.

(*From our own Correspondent.*)

ACADEMY OF MEDICINE IN IRELAND.

A SPECIAL meeting of the members of the Academy will be held at the College of Physicians on the 26th inst., to consider the advisability of applying for Her Majesty's permission to prefix the word "Royal" to the present title of the Academy. The presentation of an address to Her Majesty on the occasion of her jubilee will also be under consideration.

PROPOSED AMALGAMATION BETWEEN TWO MEDICAL SCHOOLS IN DUBLIN.

The proposed amalgamation scheme between the medical school of the Royal College of Surgeons in Ireland and the Carmichael school, about which such sanguine expectations were formed, has again fared badly. At a meeting of the Council of the College of Surgeons last week the matter was under discussion, when the proposal was negatived by 11 to 7 votes. The result has not been unexpected by those who were aware of the difficulties which lay in the way of the proposed scheme.

SIR P. DUN'S HOSPITAL.

The chief maintenance of this hospital has been from the endowment by its founder Sir Patrick Dun, which heretofore has brought in an annual income of from £1200 to £1500. The non-payment of rents in Ireland, however, has gradually diminished this amount, and last year the sum accruing to the institution was only between £300 and £400. A special appeal has been made for funds, and it is to be hoped that it will not be made in vain. There is one circumstance connected with the medical and surgical staff which deserves to be circulated, and that is that one-third of the fees paid by the students attending the hospital is devoted to its maintenance. So far as I am aware, such an arrangement does not exist in any other Dublin hospital, and therefore every credit should be given for this generosity on the part of the medical staff of Sir P. Dun's Hospital.

CASE OF STRANGULATED HERNIA.

A female aged seventy was recently admitted into the Adelaide Hospital, under the care of Mr. Heuston, for strangulated hernia of the right side. On Mr. Heuston operating, he found that the right ovary and Fallopian tube were in a gangrenous condition, and therefore removed them. Such a complication is so rare that its occurrence is worth recording. The patient has made a good recovery, the wound having healed by first intention.

THE CONJOINT SCHEME.

The proposed scheme between the Colleges of Surgeons and Physicians seems at present to be in a very unsettled condition. The proposal of the College of Surgeons to combine with the Apothecaries' Hall of Ireland, appears to be resented by the College of Physicians, and I understand that they have intimated to the Council of the College of Surgeons that should the combination be carried out the agreement between the two Colleges will be at an end, and they will require to consider the entire scheme, especially with reference to the fees to be divided between the two corporations. If the scheme between the two Colleges is abandoned, the College of Physicians will probably regret their decision.

DUBLIN HOSPITALS COMMISSION.

The report of the Commissioners has not yet been issued to the public, and the delay appears inexcusable. The following are stated to be the main suggestions of the Commissioners, but I am not prepared to vouch for them. They recommend that a central board of control be appointed, to consist of the Archbishop of Dublin, the Moderator of the Presbyterian Church, the Roman Catholic Archbishop, the Chairman of the Dublin Hospital Sunday Fund, two members from the College of Physicians, two to be nominated by the Crown, and one each by the Royal College of Surgeons, the University of Dublin, and the Royal University; while three will be selected by the Dublin Corporation. The Government fund will be vested in this board, who will allocate the grants calculated on the amount of work done by the various institutions and the donations and subscriptions received by them. None of the present institutions reported upon are recommended to be closed, but the gradual extinction of the less useful hospitals is provided for, should the recommendations of the Commissioners be carried out.

The Lord-Lieutenant has appointed Dr. McCabe to be a medical commissioner of the General Prisons Board, Ireland.

Dublin, April 20th.

Obituary.

DANIEL RUTHERFORD HALDANE, M.D., LL.D. EDIN.

THE public and professional anxiety caused by the prolonged and serious illness of Dr. Rutherford Haldane was terminated by the announcement of his death, which occurred on Tuesday, the 12th inst. His illness was the outcome of a serious accident met with on Christmas Day, 1886, when he slipped on an icy footpath and fractured his right leg. For a considerable time favourable reports were issued in regard to his progress, and the anxiety of his friends was for the time allayed and a satisfactory recovery anticipated. Latterly, however, symptoms of obstruction of the circulation appeared, and under this serious aggravation of his condition his strength rapidly gave way, and he passed gently away without a struggle. The deceased gentleman held for many years a prominent position in the Edinburgh medical world. His death leaves a most noticeable blank in many leading medical interests of the city, and a deep feeling of personal loss on the part of his wide circle of friends.

Dr. Haldane was a son of the late James Alexander Haldane, so widely known as an Evangelist, as a disinterested Christian reformer, and as a chief founder of the Scottish branch of the Congregational body. After a liberal classical education Dr. Haldane commenced the study of medicine in the University of Edinburgh. He was an able and very successful student, giving thus early evidence of the ability that so conspicuously distinguished his subsequent career. In 1848 he graduated with honours as M.D., after which he spent two years on the Continent in the prosecution of further studies, and in acquainting himself with the more practical aspects of disease. On his return he acted as resident physician to the Royal Infirmary. His career as a highly successful extra-academical teacher was commenced by his undertaking courses in medical jurisprudence and pathology. He was also for a time pathologist to the Royal Infirmary. On the retirement of Dr. Alexander Wood from the College of Surgeons' lectureship on Practice of Physic Dr. Haldane took his place, and it was as a teacher of medicine and of clinical medicine also, on his appointment to the staff of the Royal Infirmary, that he gained the reputation of a great teacher, still so warmly cherished in the minds of his numerous students. He early became a Fellow of the Royal College of Physicians of Edinburgh, a body in the welfare of which he took the deepest interest, and which he has ably represented in its presidential and vice-presidential chairs, and by acting as its representative on the General Medical Council. He was also assessor of the General Council of the University of Edinburgh in its University Court, and his services to his *alma mater* were recognised by the conferring upon him of the honorary degree of LL.D. at the Tercentenary Festival. On the expiry of his term of office on the honorary staff of the Royal Infirmary, he continued his connexion with that institution, firstly as consulting physician and subsequently as one of its managers. In addition to his multitudinous public duties he engaged in a wide practice as a consulting physician, and he was a genial and capable arbitrator in the many weighty matters of professional importance brought under his notice by widely differing sections of the medical community. His personal no less than his professional qualifications gave him the position of a leader in the Edinburgh medical world and of a much-respected public man. In both spheres he is keenly missed, and deeply regretted.

HENRY GRENFELL, M.R.C.S., L.S.A.

MR. HENRY GRENFELL was born in 1837 at St. Just-in-Penwith, near the Land's End, and educated at Penare House School, Penzance. After having served an apprenticeship with Mr. W. H. Dodge at Penzance, he entered at King's College, London, in 1856, and, soon attracting notice as a diligent student and a skilful dissector, was appointed a prosector to the Royal College of Surgeons. He became a dresser to the late Professor Partridge and a clinical clerk to Dr. George Budd, and was most earnest and assiduous in the discharge of his ward duties. He took his double qualification in 1861, and settled at once in practice at Penzance. He was warmly interested in the Volunteer movement, and served as medical officer in every grade in the western division of the Duke of Cornwall's Royal Artillery, being Surgeon-Major at the time of his death. For some years he had been the acting surgeon to the Penzance Infirmary, and had acquired a wide reputation as a skilful, bold, and careful operator, and as an able exponent of the principles and practice of antiseptic surgery. His death was sudden and unexpected. He had always enjoyed perfect health until two or three weeks ago, when he began to complain of headaches and a slight discharge from the left ear, to which he paid but little attention. On the 9th inst. he suddenly became comatose, and trephining was resorted to, but he never regained consciousness, and died on the 10th inst. at 4 A.M. A post-mortem examination showed the existence of caries of the roof of the tympanum, and extensive purulent meningitis over the anterior lobes of the brain. By his early death at the age of forty-nine, the profession in West Cornwall is deprived of a most capable surgeon, and his family and numerous friends and patients will long regret the loss of a most genial, kindly, and true-hearted man.

DR. DANIEL WANE.

THIS gentleman, whose death was announced on April 5th, at the age of seventy-three, was a M.D. Edin., M.R.C.P. Lond., and a Fellow of the Medical, Medical and Chirurgical, and Obstetrical Societies. He had a large and high-class practice in Grafton-street, Piccadilly, where he practised for many years. His kindness of heart and intense conscientiousness in the smallest details of his profession won for him the love and esteem of all with whom he was brought in contact. He had retired from practice for the last four years, and died at his house in Fitzjohns-avenue from a seizure of an apoplectic nature.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The following gentlemen have passed the examination for the Membership of the College:—

Ballantyne, J. W., M.B. Edin. | Rinder, A. W., L.R.C.P. Edin.

The following have passed the Public Health Certificate Examinations:—

Kiddle, W., M.B. Dub. | Robinson, E., M.R.C.S. Eng.

Dr. Woodhead has been appointed Superintendent of the College Laboratory.

UNIVERSITY OF ABERDEEN.—At the late Medical Graduation term, the following candidates, after the usual examinations, received degrees in Medicine and Surgery:—

DEGREE OF M.D.

Alexander, Lewis Daniel, M.B., C.M., Kilcreggan, Greenock.
Carbery, Joseph, M.B., C.M., Matale, Ceylon.
Cheyne, Walter Smith, M.B., C.M., Aberdeen.
Dickson, Matthew, M.B., C.M., Liverpool.
Fallon, Robert Hume, M.B., C.M., Clifton.
Fildes, Thomas, M.B., C.M., Urmston, Manchester.
Gerard, John, M.A., M.B., C.M., Aberdeen.
Hardie, David, M.B., C.M., Brisbane, Queensland.
Letters, Patrick, M.B., C.M., Dundee.
Smith, Ernest Barret, M.B., C.M., Twickenham.

DEGREES OF M.B. AND C.M.

Alexander, William, M.A., Fyvie.
Beveridge, Alexander Thomas Gordon, M.A., Aberdeen.
Brooks, John Harley, London.
Brown, Alfred Tennyson, Banchory.
Bryce, James, Aberdeen.
†Butter, John Soutar, Lotham, Forfar.
Crevie, James, Newburgh, Aberdeen.
Crowe, William Christie, Aberdeen.
Dalgarno, James John Young, M.A., Aberdeen.
*Davidson, David Macdonald, Mauritius.
Duff, Charles Edmund, Turriff.
Fraser, James Winton, Arbroath.
Fyfe, Thomas Henderson, Aberdeen.
Henry, George, M.A., Aberdeen.
Holden, Joseph Eatough, Bolton, Lancashire.
Kelman, George Alexander, Fearn, Ross-shire.
Macdonald, George Bothwell Douglas, Aberdeen.
Manning, Leslie Samuel, Christchurch, New Zealand.
Melvin, James, Aberdeen.
Myles, John Coutts, Aberdeen.
Nicol, Patrick John Smith, Aberdeen.
Pearson, Joseph, Sheffield.
Pirie, James, M.A., Elgin.
Rannie, Robert, Glenbucket.
†Shand, Jonathan, Keith.
Smith, Robert, Aberdeen.
Souter, Charles Henry Joseph, Emmaville, New South Wales.
Souter, John, M.A., Aberdeen.
†Thomson, Thomas Harvey, Stonehaven.
Urquhart, Charles Thiselton Dyer, Aberdeen.
Walker, Frederick William, Darlington.
Webster, James, Aberdeen.
White, Cresswell Fitzherbert, Chippenham, Wilts.
Wilson, George Nicol.

* Highest Academical Honours. † Honourable Distinction.

At the same time the following gentleman was certified to have passed all the examinations, and that he should receive his degrees in Medicine and Surgery with "Honourable Distinction," but did not graduate:—

Ker, George William England.

UNIVERSITY OF GLASGOW.—The following gentlemen have passed the Third Professional Examination for the degrees of M.B. and C.M.:—

Banks, Robert.
Bannatyne, Gilbert A.
Blackburn, Thomas L.
Blair, Alexander.
Bland, Matthew H.
Buchanan, Robert M.
Charles, John.
Copland, Andrew.
Cowen, Herbert O.
Gemmell, William.
Gillespie, J. Paterson.
Jago, Arthur H.
M'Conville, John S., M.A.
M'Glashan, James.
Melville, John.
Monro, Thomas K., M.A.
Niven, Charles R.
Norris, Frederick L.
Paton, William R.
Pinkerton, Robert L., M.A.
Rankin, John S.
Robb, William.
Sandilands, John, M.A.
Wallace, James.
Wilson, James P.
Wylie, Richard J.
Young, James.

The following have also passed in Pathology:—

Boyle, Michael A.
Cameron, Thomas.
Campbell, Archibald.
Curle, David.
Gunn, Archibald.
Hallett, Charles H.
Hamilton, Wm. Cowan.
Harrison, Edward O.
Hay, Thomas Wm.
Innes, Andrew.
Jenkins, Thomas W., M.A.
Kirkland, Hugh.
Laird, Thomas.
Lang, Ebenezer.
M'Kendrick, John.
Sloan, Hugh R.
Wildridge, Charles M.

ST. ANDREWS UNIVERSITY.—The following degrees were conferred on April 20th:—

DEGREE OF M.D.

Charlesworth, Samuel, Hirst, Bradford, Yorks.
Greaves, Charles Henry, Stafford.
Hackney, John, Hythe.
Havard, David, Newport, Pembroke.
Jackson, Jabez Bunting, Birmingham.
Le Page, John Fisher, Salford.
Lyall, Andrew, Leven.
Mac Bain, Hugh Gilles, North Berwick.
Mitchell, Joseph, New Wortley.
Stone, Valentine, Montrose.

DEGREE OF M.B.

Fayrer, Joseph, M.A., Edinburgh.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on April 14th:—

Bishop, Charles Rosser, M.R.C.S., Craven-hill, Hyde-park.
Dickinson, John Clough Hardman, Bow-road.
Hinnell, Joseph Squier, Garland-street, Bury St. Edmunds.
St. Johnston, Charles, Easy-row, Birmingham.
Roe, H. Havilland, M.R.C.S., Woburn-place, Russell-square.
Tonks, H., M.R.C.S., Packwood, Grange, Knowle, Warwickshire.

GUY'S HOSPITAL FUND.—A sermon will be preached in the church of St. Saviour, Southwark, on Tuesday evening, April 26th, by the Lord Bishop of Liverpool, on behalf of the fund of £100,000 which is being raised for the above hospital.

Digitized by Google

THE annual meeting of the governors of the Carmarthenshire Infirmary was held on the 12th inst., when satisfactory reports were presented and adopted.

A SUPERANNUATION grant of £67 per annum has been made to Mr. Thomas Gray, late medical officer to the Poplar Board of Guardians.

NEWSVENDORS' BENEVOLENT AND PROVIDENT INSTITUTION.—Sir A. K. Rollit, M.P., LL.D., will, we are informed, preside at the festival of this Society, to be held at the Grand Hotel, Charing-cross, on Wednesday, June 22nd.

VACCINATION GRANT. — Mr. J. B. Muirhead, M.B., Malling Union, has received the Government grant for efficient vaccination in the second district of the above union (first time).

FIRST AID.—At the distribution of certificates to the pupils of the first aid classes at Norton St. Philip, near Bath, the members of the classes presented the lecturer, Mr. W. Godfrey Evans of Beckington, with a very handsome carriage clock.

GUY'S HOSPITAL.—The Michael Harris Prize in Anatomy of £10 has been awarded to Mr. Frederick William Hall, of Sydney, New South Wales; and the Beaney Prize in Pathology of 30 guineas has been awarded to Mr. Theodore Fisher of Greenwich.

GLASGOW EAR HOSPITAL.—At the annual meeting of patrons and subscribers of this hospital, held on the 13th inst., Dr. James Erskine, recently assistant-surgeon to the hospital, was elected a member of the board of directors of that institution.

THE sanatorium which has been erected at Bradwell jointly by the Wolstanton and Burslem Rural Sanitary Authority, the Wolstanton and Burslem Guardians, the Burslem Corporation, and the Tunstall Local Board, was opened on the 6th inst.

DURHAM COLLEGE OF MEDICINE.—A deputation from this College is, we learn, about to wait on the Lord President of the Council with the object of obtaining a Government grant towards the building fund of the institution.

FATAL FOOTBALL ACCIDENT.—At an inquest held at Macclesfield on the 14th inst., the jury returned a verdict of accidental death in the case of a kick in the stomach during a match for the benefit of another player, who had his leg broken.

PROPOSED HOSPITAL AT MONTREAL.—Sir George Stephen, president of the Canadian Pacific Railway, and Sir Donald Smith, one of the directors, have, it is announced, addressed a letter to the mayor of the city offering to contribute a million dollars for a hospital for the city poor, to be named the Royal Victoria Hospital, and to be erected on a site which they hope the city authorities will grant on the slope of Mount Royal.

LEDWICH SCHOOL OF MEDICINE, DUBLIN.—At the termination of the winter session the following prizes were awarded:—Junior Anatomy: Henry Cullman, 1st; J. C. Ryan, 2nd. Senior Anatomy: D. Shanahan, 1st; J. P. O'Meara, 2nd. Surgery: W. J. Thompson, 1st; D. L. Hamilton, 2nd. Practice of Medicine: J. D. Sexton, 1st; P. Rowan, 2nd. Physiology: J. R. Steen, 1st; J. B. Wilkinson, 2nd. Midwifery: D. L. Hamilton. Theoretical Chemistry: C. M. O'Brien.

MIDLAND VOLUNTEERS' MEDICAL ASSOCIATION.—The second annual meeting of the members of this Association was held on the 13th inst. at Birmingham, under the presidency of Surgeon-Major Thompson. It was reported that the work of the year had been extremely satisfactory, but that the medical staff connected with the Volunteers at the present time would be altogether inadequate in case of active service. This is due to the action of the War Office, which declines almost entirely to support or assist them. The Association has also been successful financially, a small balance remaining in the treasurer's hands after payment of all the expenses of the preceding year.

NEW MORTUARY FOR HACKNEY.—On the 6th inst. the Hackney District Board of Works, after a long discussion, decided to purchase a piece of ground and erect a mortuary, post-mortem room, and a room for the reception of the bodies of persons who have died from infectious diseases, at an estimated cost of £1250. This step was taken in consequence of the many complaints which have been received of the great want of accommodation in this respect.

ASYLUM ACCOMMODATION IN PORTUGAL. — In an account of the work done in Count Ferreira's hospital, or rather lunatic asylum, in Oporto, by the director, Dr. A. M. de Senna, a distinguished Portuguese alienist, which has just been published, the author complains bitterly of the great lack of asylum accommodation in Portugal, saying, "Portugal does not succeed in finding room in asylums for a seventh part of her mentally afflicted population, while in England nine-tenths of such persons are provided for."

SEMI-CONVALESCENT HOME AT COOKRIDGE.—By the munificence of Mr. John North of Leeds, a semi-convalescent home is about to be erected at Cookridge as an adjunct of the Leeds Infirmary. Building operations have been commenced, and it is expected that the establishment will be ready for occupation about the beginning of 1888. Room will be provided for forty-two beds at first, with additional accommodation if required. The estimated cost, exclusive of furnishing, is £5000, and this sum has been already advanced by Mr. North.

THE NATIONAL HOSPITAL FOR CONSUMPTION AT VENTNOR.—The festival dinner in aid of the funds of this institution was held on Tuesday, the 19th. The Duke of Cambridge, who presided, pointed out the advantages of such a hospital in cases of diseases of the chest, and mentioned that since its foundation in 1868 it had helped 7384 patients. There are now 118 beds, and later in the year this number will be increased by 20 more. An earnest appeal was made for funds, and during the evening a list of donations and subscriptions was read, the total amounting to about £2400.

BUTTER ADULTERATION IN KENT.—The analyst for the county of Kent has submitted a report to the Finance Committee of the Court of General Sessions on the subject of the adulteration of butter, in which he says that during the past quarter thirty-two samples were examined, and seven found to be adulterated with foreign fat, with a range of from 20 to 92 per cent., giving a mean rate of 54·25 per cent. of adulteration. This falsification of butter by the admixture of foreign fat, and not, as was formerly the case, by complete substitution, is a fraud much more difficult of detection by the analyst, and quite impossible to the ordinary public.

ANOTHER THAMES VALLEY DRAINAGE BOARD.—On the 13th inst. a Local Government Board inquiry was held with reference to an application by the Richmond Urban Sanitary Authority and the Richmond Rural Sanitary Authority for a Provisional Order to form their two districts into a united district, under Section 279 of the Public Health Act, for sewerage purposes; such Provisional Order to provide for the constitution of a joint board to act as the governing body of the united districts. The parishes affected include Richmond, Mortlake, Barnes, Kew, and Petersham, and the new board will have powers similar to those which were exercised for some years by the now defunct Lower Thames Valley Main Sewerage Board. There is no opposition to the application.

HUNTINGDON COUNTY HOSPITAL.—At a meeting of the governors of this charity held on Tuesday last, the Earl of Sandwich presiding, the Duke of Bedford, Lord-Lieutenant of the County, and the Bishop of Ely, were elected patrons of the institution. The Duke of Bedford has intimated his intention of giving £100 to the funds of the hospital. A vote of condolence with the family of the late Mr. Philip Tillard, chairman of Quarter Sessions, was also passed. Mr. Tillard had been honorary secretary of the hospital for nineteen years, from its establishment in 1853. It will be remembered that the hospital adjoins the Great Northern Railway at Huntingdon, and was of great public service at the time of the terrible collision at Abbots Ripton some years ago.

Digitized by Google

RABIES AMONGST DEER AT RICHMOND.—At the Richmond Petty Sessions on the 20th inst. an outbreak of rabies among the deer in Richmond-park was reported. About one hundred of the animals have been affected, and consequently destroyed. Every precaution is being taken to prevent the spread of the epidemic, the herd which has been attacked having been completely isolated.

MEDICAL NOTES IN PARLIAMENT.

The Vaccination Acts.

In the House of Commons on the 14th inst., in reply to Mr. Channing, Mr. Ritchie stated that he could not undertake to intervene in any individual case of repeated prosecution for non-compliance with the Vaccination Acts, nor was he prepared to propose legislation which would take away from the guardians, who have the advantage of knowing fully the local circumstances, their freedom of action in the matter.

Army Medical Officers.

In answer to Dr. Tanner, Mr. E. Stanhope stated that army medical officers, as he had already several times explained, will be exactly in the same position as they have hitherto been.

The Sanitary Condition of Barracks.

On the 18th inst., Mr. Norris asked the Secretary of State for War whether any further information had reached him as to the sanitary condition of the barracks at Dover contradictory of the statement contained in the report of the principal medical officer there and the Commanding Officer of Royal Engineers, quoted by him on Feb. 8th last, "that they had failed to discover any insanitary conditions;" whether the death of another young officer, Mr. Keegan, and the illness of a private soldier were attributable to typhoid fever contracted in the barracks; and, if so, whether he would cause immediate and searching inquiry to be made into all the facts of those cases, which followed so closely on the death of Lieutenant Jarrett, of the Buffs, from the same disease; and if he would state whether complaints had reached him as to the insanitary condition of other barracks.—Mr. E. Stanhope replied that according to a report received that morning careful investigation has failed to discover in Fort Burgoyne, where these cases of enteric fever occurred, any insanitary conditions which will account for the disease; but a further minute inspection is to be made and steps taken to remove immediately every possible source of disease to which any suspicion can attach. In answer to the third question, he stated that complaints had been received from other barracks also, and the Government would in every case, if the complaint appears to be well-founded, remedy it with the least possible delay.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BIRCH, ROBERT, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Workhouse of the Newbury Union.

BROWN, F. L. HARMAN, M.B., C.M.Edin., has been appointed Second Assistant Medical Officer to the Norfolk County Asylum.

CLARK, MALCOLM R., L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Medical Officer for the Harthill District of the Worksop Union.

COLT, THOMAS A., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Portsea District of the Portsea Island Union.

DAVIDSON, JOHN, M.B., C.M.Ed., has been appointed Medical Officer for the South Wallasey District of the Birkenhead Union.

GALLOWAY, ARTHUR W., L.R.C.P.Lond., M.R.C.S., has been appointed a District Surgeon to the City of London Lying-in Hospital, vice Thomas, resigned.

HART, WALTER, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Fourth District of the Chelmsford Union.

HAYDEN, WILLIAM G., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Third District of the Royston Union.

HOPE, E. W., M.D.Ed., has been appointed Visiting Medical Officer to the City Hospital, Park-hill, Liverpool.

JESSOP, WALTER H., M.B., F.R.C.S., has been appointed Surgeon to the Central London Ophthalmic Hospital, vice W. Charnley, M.D., resigned.

JONES, JOHN O., M.B., C.M.Ed., has been appointed Medical Officer for the Llanfairtalhaiarn District of the St. Asaph Union.

LITTLE, W. MAXWELL, M.B., C.M.Edin., late Second Assistant Medical Officer, North County Asylum, has been appointed Senior Assistant Medical Officer, vice T. J. Compton, M.B., C.M., resigned.

LLOYD, K. M., M.R.C.S., has been re-elected Medical Officer of Health by the Holywell Local Board.

MACINDOE, ALEXANDER, M.D.Glas., has been appointed Medical Officer for the Alderley and Gawsworth District of the Macclesfield Union.

MARTIN, SIDNEY, M.D.Lond., B.Sc., M.R.C.P., has been appointed Pathologist to the City of London Hospital for Diseases of the Chest, Victoria-park, E.

MCDONALD, B. F. P., M.D.Ed., has been appointed Medical Officer for the North Wallasey District of the Birkenhead Union.

MICKLE, JULIUS, M.D.Lond., M.R.C.P., has been appointed Lecturer on Psychological Medicine at the Middlesex Hospital Medical School, vice Case, resigned.

SOUTHERN, JOHN ACTON, L.R.C.P.Lond., has been appointed House-Surgeon to the Derbyshire General Infirmary, vice E. C. Green, M.R.C.S., L.R.C.P.Lond., resigned.

WOODHEAD, GERMAN SIMS, M.D., F.R.C.P.Ed., F.R.S.Ed., has been appointed Superintendent of the new Laboratory, Royal College of Physicians, Edinburgh.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BRISTOL ROYAL INFIRMARY.—Assistant Resident Medical Officer and Pathologist. Salary £80 per annum, with board, lodging, and washing.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C.—House-Surgeon. Rooms, gas, and firing.—Assistant Surgeon.

CHELTENHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Salary £40 per annum, with board and apartments.

COUNTY AND BOROUGH OF CARMARTHEN INFIRMARY.—House-Surgeon. Salary £100 per annum, with board, lodging, fire, light, and washing.

COUNTY ASYLUM, Stafford.—Resident Medical Officer and Superintendent. Salary £500 per annum, with unfurnished residence within the Asylum, and £200 in lieu of board.

Medical Diary for the ensuing Week.

Monday, April 25.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

RESEARCH SCHOLARSHIPS OF THE GROCERS' COMPANY.—5 P.M. Mr. W. North: Malarial Fevers.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Bruce Clarke: A peculiar Congenital Papilloma of the Thigh.—Mr. William Rose: A case of Severe Injury to the Wrist-joint requiring Suture of Nerves and Tendons.—Mr. F. B. Jessett: (1) A case of Plastic Operation on the Nose; (2) A case of Removal of a Large Cystic Growth from the Neck implicating the Submaxillary Gland.—Mr. Bernard Pitts: A case of Congenital Curvature of the Spine.—Mr. Marmaduke Sheild: Case of Tumour of the Neck greatly reduced in size by Arsenic.

Tuesday, April 26.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

ROYAL INSTITUTION.—3 P.M. Prof. W. E. Ayrton: Electricity.

SOCIETY OF ARTS.—8 P.M. Mr. J. Hungerford Pollen: Ornamental Glass.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. Warner and Dr. Fletcher Beach: A case of Chronic Meningitis, probably Syphilitic, and causing Progressive Dementia.—Dr. Poore: An Analysis of Ninety-three cases of Writers' Cramp and Impaired Writing Power, making, with seventy-five cases previously reported, a total of 168 cases.—Dr. Haig: The Relation of a certain form of Headache to the Excretion of Uric Acid.

Wednesday, April 27.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M. Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M. Saturday, same hour.

SOCIETY OF ARTS.—8 P.M. Mr. Arthur W. C. Shean: Appliances for Saving Life from Fire.

HUNTERIAN SOCIETY.—8 P.M. Dr. A. J. Davies: Cases of Myxœdema.—Dr. Dundas Grant: A case of Carcinoma of the Œsophagus perforating the Trachea.—Dr. Port: (1) Two cases of Pseudo-hypertrophic Paralysis; (2) On Antipyrin.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Drs. Edis, Fancourt Barnes, G. Granville Bantock, Mr. Lawson Tait, and others. Council at 8 P.M.

Thursday, April 28.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The Chemistry of the Organic World.

RESEARCH SCHOLARSHIPS OF THE GROCERS' COMPANY.—5 P.M. Mr. W. North: Malarial Fevers.

Friday, April 29.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

SOCIETY OF ARTS.—8 P.M. Mr. J. F. Hewitt: Village Communities in India.

ROYAL INSTITUTION.—9 P.M. Prof. H. S. Hele Shaw: The Rolling Contact of Bodies.

Saturday, April 30.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. R. Von Lendenfeld: The Australian Alps and the Origin of the Australian Fauna.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

DR. BRUNTON AND HOMŒOPATHY.

Dr. Dudgeon is not satisfied that Dr. Brunton will not confess more obligation to homœopathy than he does, and sends us another letter in the same strain as one we lately published. He must excuse us saying that we cannot continue the discussion. We think Dr. Brunton's estimate of homœopathy sound in point of sense and scientific. We think that Dr. Brunton's Therapeutical Index will be the better for even more expurgation than it has received. This will probably make it less trying to homœopaths and more useful to general practitioners; but this is not of the essence of the question of homœopathy or of Dr. Brunton's opinion of it.

Mr. W. Robinson.—Our correspondent is probably referring to cases of nebula of the cornea, which were at one time treated with prussic acid. Cataract was never cured by this means.

Constant Reader.—1. Lauder Brunton's Pharmacology, Therapeutics, and Materia Medica, or Beasley's Formulary, contain the directions desired.—2. Sp. vini rect.

MEDICAL OFFICERS OF HEALTH AND PRISON SURGEONS.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me whether the medical officer of health of a town is justified in visiting H.M. prison and union workhouse with a view to ascertaining their sanitary condition and reporting upon the health of the inmates without requesting the co-operation or sanction of the medical officer of those institutions, or in any way communicating with him?

I am, Sirs, yours truly,

M. O. H.

*** The Public Health Act apparently contemplates that a medical officer of health shall inform himself of the sanitary circumstances of all portions of his district, including the institutions within it. But where an institution has a medical officer who is responsible for its control and management, the necessary information can usually be obtained from this officer, and it is, as a rule, unnecessary for the medical officer to intervene. Where such intervention becomes necessary, under any special circumstances, it should always be effected in co-operation with the officer of the institution. In the case of prisons, which are under the control of a Government department having a medical staff of their own, and to which access by any but prison officials may properly be denied, it can rarely be requisite for an officer of health to claim a right of entry; and if such entry should be necessary in connexion with the work of his district, it should certainly be secured with the co-operation of the prison medical officer.—ED. L.

AN INTERESTING CONSIGNMENT.

DR. MACALISTER, F.R.S., the Professor of Anatomy in the University of Cambridge, has, it is stated, just received a case of skulls from Egypt representing different types of people at different periods of the history of that country. By examination and comparison he hopes to arrive at sound conclusions as to the races to which the owners of these skulls belonged.

Perplexed.—We quite agree with our correspondent that his patient would be acting unwisely in adopting the course suggested.

N.—Our correspondent will see that the question upon which he writes has been solved in a satisfactory manner.

A Country Doctor is referred to THE LANCET of last week, page 795.

THE LATE DR. HUTTON.

To the Editors of THE LANCET.

SIRS,—The help of the benevolent is solicited on behalf of the family of Dr. Hutton, late of 36, Lowndes-street, whose death was recently noticed in your columns. Dr. Hutton's course, though one of industry, self-denial, and probity, was not rewarded by pecuniary success. Some of his excellent qualities were not such as lead to worldly prosperity, and even in some respects militate against it. He began life with a small patrimony; but this was sacrificed in the interest of a near relative, without any fault on Dr. Hutton's part, excepting that he was too trustful and too unselfish. Upon this part of the sad story it is not needful to dwell. Dr. Hutton's practice, once considerable, of late years diminished until the daily earnings scarcely provided the daily needs, though these were made matters of the most rigid economy. When the end came there was found to be nothing, or, rather, something less than this. There is a son who holds a commission in the army, which it is trusted he may not have to give up. He is thus provided for; but his pay does not suffice to maintain his relatives. The widow and two unmarried daughters are left with no means of support. The widow, who is advanced in years and is the subject of a painful disease, has a double claim on the profession, since she is the daughter of the late Dr. Seymour, once well known as physician to St. George's Hospital. It is hoped that some who have been less unfortunate than Dr. Hutton, or more successful, will give out of their abundance towards a fund which is being raised for the purpose of saving these ladies from absolute want. How it can best be used will depend on the amount; it shall be guarded carefully, and employed judiciously. Some of the leaders of the profession, as well as some of Dr. Hutton's attached friends, have already subscribed liberally. It is hoped that this appeal to a wider circle may be also responded to. The gentlemen whose names follow have agreed to form a committee for the collection and management of the fund:—L. Cumberbatch, M.D., W. H. Dickinson, M.D., Sir Joseph Fayrer, Geo. Faudell Phillips, Esq., G. D. Pollock, Esq., R. Stewart, Esq., W. Wadham, M.D. Dr. Cumberbatch, 25, Cadogan-place, Belgrave-square, S.W., as treasurer, will be glad to receive and acknowledge subscriptions. Cheques should be made payable to him. The following sums have already been subscribed:—

Sir Prescott Hewett	...	£52	10	0	Sir Benjamin Phillips	...	£5	5	0
Geo. Faudell Phillips, Esq.		50	0	0	S. H. Phillips, Esq.	...	5	5	0

I am, Sirs, your obedient servant,
W. HOWSHIP DICKINSON,
April, 1887. Secretary of the Committee.

A Constant Reader.—We have not heard that such an intention has been expressed by any of the various licensing bodies.

Mr. Johnson (Liverpool).—We regret to be unable to assist our correspondent.

"BREAD-MAKING."

To the Editors of THE LANCET.

SIRS,—In answer to the letters of Mr. Robert Jones and "H.," permit me to say that a pamphlet was published about the year 1850 on the subject by a "Dr. Dagleish," or "Dalgleish."—Yours truly,
April, 1887. NO-NATION.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Can any of your correspondents inform me how to prepare the metal, or amalgam rather, used in making children's tin (so-called) toys and capsules for bottles, together with the names of manufacturers of the latter. I require the amalgam for health purposes.

I am, Sirs, yours truly,
April, 1887. J. W.

"SHAM PATIENTS."

ANOTHER correspondent, Mr. R. J. Hutton, of Stapleton Hall-road, N., writes to say that his consulting-room has also received an unwelcome visit from probably the same scoundrel who relieved Drs. Longhurst and Low of valuable property. In the case of Mr. Hutton, the thief managed by picking a lock to decamp with seven sovereigns as plunder.

Miss Keightley.—We do not issue reprints of separate articles which have appeared in THE LANCET.

A. G. P. will see that we allude to the question in an answer to another correspondent.

SUDDEN DEATH.

To the Editors of THE LANCET.

SIRS,—"I fear you are too late," said the husband, as he hurried me to the apartment where his wife, from sudden failure of the heart's action, was lying insensible, and, as the nurse informed me, "dying." It was impossible to administer by the mouth a restorative, so without delay I injected hypodermically twenty drops of ether, sp. gr. 0·720, and, as the improvement was not as quick as I desired, forthwith twenty drops more. To the complete astonishment and great delight of the friends, consciousness and strength rapidly returned.

The sudden deaths which have so lately thrilled the public mind, more especially the death of Lord Iddesleigh in London and Mr. Christopher Bushell here, have influenced me to send you the above record, not as the proclamation of a new discovery, but as a suggestion—a suggestion in connexion with the alarming newspaper reports, which usually run somewhat thus:—"Mr. —— suddenly became ill, when, sinking, he was supported by his friend. Dr. ——, who happened to be present, was most assiduous in his attention, but at last pronounced life extinct." Should it not be impressed on the public that the easiest mode in which respiration can be carried on is when the body is extended at full length—not lying on the back, but with the inclination towards the prone position? Nature throws down to assist the encumbered circulation; the officious kindness of indiscretion and ignorance supports the fainting sufferer. Again, would it not be well in these times of frequent sudden deaths from weakened hearts that each medical man should have in his possession, ready for immediate use, his hypodermic syringe case, with its little bottle filled with ether? Would it not be well, too, that the possessor of a weak heart, or, better still, the friend who accompanies him, should also have the ether and syringe ready for instant employment. Ladies with neuralgia practise hypodermic injections of morphia by the advice and under the direction of physicians. This I would condemn. But the friend of a valuable life, the tenure of whose leasehold is uncertain through the possession of a weakened, or flabby, or a fatty heart, might well be instructed in the use of the subcutaneous injection of ether. More than one example might be adduced to show that the immediate stimulant might rouse the flagging pulse-throb; and then, instead of the announcement that "life was extinct," one might read that after the injection the appalling symptoms quickly passed away, and what appeared to be approaching death gave place to the renewed energy of life, with all its usefulness.

I am, Sirs, yours faithfully,
Liverpool, Feb. 23rd, 1887. W. H. LAMBART, M.D.

FLEXIBLE STETHOSCOPES.

To the Editors of THE LANCET.

SIRS,—In reference to the rubber stethoscope mentioned in your last issue as a new invention, permit us to say that many years ago we constructed the same indiarubber stethoscope from a design furnished us by Dr. B. W. Richardson; that it is fully described, with its advantages, in the *Æsculapiad*, vol. i., page 162-3, 1864; and that we have supplied the profession with it repeatedly, the instrument being much appreciated. The advantage you refer to, that it does not injure the instrument to sit upon it, is noticed in the paper above referred to. Dr. Richardson, we believe, does not use any other stethoscope.

We are, Sirs, yours respectfully,
Duke-street, April 18th, 1887. KROHNE AND SESEMANN.

BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Would you kindly allow me to acknowledge the receipt of the following contributions to the above fund?

Thomas Smith, Esq., F.R.C.S.	...	£3	3	0	Dr. Frazer	... £1	1	0
Dr. Broadbent	...	2	2	0	Dr. Grey Glover	... 1	1	0
Lennox Browne, Esq.	...	1	1	0	Dr. Robert Barnes	... 1	0	0
Dr. Holman (Reigate)	...	1	1	0	J. H. T. Connor, Esq.	... 0	10	6
Benj. Duke, Esq.	...	1	1	0	M. G. Biggs, Esq.	... 0	10	6
					J. T. Boyd, Esq.	... 0	10	6

I am, Sirs, yours faithfully,
Meadow Side, 23, Upper Richmond-road, Putney, April 20th, 1887. G. STANLEY MURRAY.

THE ASSOCIATION OF GENERAL PRACTITIONERS.

To the Editors of THE LANCET.

SIRS,—I hope the above powerful advocate of the rights of the masses will favour us here in Ireland with a meeting next August, on the occasion of the British Association gathering in Dublin. Irish provincials need stirring up, and a little Saxon backbone will do them no harm.

I am, Sirs, yours truly,
Cashel, April 16th, 1887. THOMAS LAFFAN.

LANGMORE DEFENCE FUND.

IN response to the appeal which recently appeared in THE LANCET several donations have been forwarded; but a sum of £122 is still required to pay the legal expenses necessarily incurred by Dr. J. Wreford Langmore for his defence in the recent trial, although he obtained the verdict of the jury with full costs. Subscriptions should be sent to Mr. George Eastes, M.B., 69, Connaught-street, Hyde Park-square, London, W.

Second List of Subscribers.

Mr. G. E. Walker.—We know of no institution where the suggestion is acted upon; but it appears worthy of consideration.

M.R.C.S. is referred to an article on the subject which appeared in THE LANCET of Nov. 20th last.

Mr. B. B. Joll will find his question answered in our current issue.

R. N.—Once or twice daily.

ABDOMINAL PALPATION.

To the Editors of THE LANCET.

SIRS,—I am informed that in one of the numbers of your journal the statement was made that the method of abdominal palpation was not taught in any of the medical colleges. I take pleasure in mailing to you to-day one of the announcements of the Long Island College Hospital, by which you will see that, whatever may be true of other colleges, this one recognises the value of this means of diagnosis. I may also add that this plan has been carried out with us for two years past.

I am, Sirs, yours very truly,

J. H. RAYMOND, Secretary.

Long Island College Hospital, Brooklyn, N.Y., April 7th, 1887.

Dr. C. E. Monro (Penge).—If the notice arrived, and we have no recollection of it, it has been mislaid.

Dr. Glanville.—The formula was given in our issue of March 26th.

Dr. J. Hardie's letter is crowded out this week.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from — Sir Dyce Duckworth, London; Dr. Braxton Hicks, London; Dr. Dickinson, London; Mr. Harrison Cripps, London; Herr Fischer, Jena; Mr. C. Higgens, London; Mr. J. W. Watson, York; Mr. Walter Whitehead, Manchester; Dr. Adams, Runcorn; Dr. Forbes Winslow; Mr. Stanley Murray, Putney; Mr. Batterham, St. Leonards; Dr. C. E. Monro, Penge; Mr. Branthwaite, Willesden; Mr. Faulkner, London; Mr. Tallack, London; Mr. H. S. Jackson, Walmer; Mr. Wickham Barnes, London; Mr. H. Bramwell, Newcastle-on-Tyne; Dr. Julius Mickle, London; Mr. J. H. Raymond, Brooklyn; Messrs. Bryce and Whitelegge, Nottingham; Dr. J. Beckett, London; Messrs. Lynch and Co., London; Mr. C. H. Lectures
ON
INJURIES OF NERVES.

Delivered at the Royal College of Surgeons,

BY ANTHONY A. BOWLBY, F.R.C.S. ENG.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—My first duty is to offer you my sincere thanks for the honour you have conferred in appointing me to deliver these lectures. Believe me, I am very fully conscious of the responsibility which is incurred, and can assure you that it was not without some diffidence that I undertook the task. The subject I have chosen is Injuries of Nerves, and if any excuse is necessary for my choice, it is supplied by the fact that to this subject I have given the greater part of my spare time for the past six or seven years, and that what I submit to you is the best work I have to offer.

It is now some nine years ago, Sir, that my attention was first directed to injuries of the nerves by a case at that time under your own care in St. Bartholomew's Hospital. The patient was a man who had injured his ulnar nerve near the elbow-joint some months before admission, and you, Sir, performed the operation of nerve suture, an operation which at that time was new, and had been confined in its application to some few cases chiefly in the hands of continental surgeons. The novelty of this operation interested me, as did also the doubts expressed as to its success and the dangers attending it, and my curiosity was further aroused when I found, on seeking for more information, that there was little that was accurate and much that was speculative in the opinions expressed by writers on the subject. A year later another operation of a similar kind was performed by Mr. Holden; and in 1880, when acting as his house-surgeon at St. Bartholomew's Hospital, I had opportunities myself of treating by suture several divided nerves. From this time forward I determined to solve by my own observations, if possible, those problems to which I could not obtain a satisfactory answer in published works, and was stimulated to additional efforts by the award of the Jacksonian Prize of the Royal College of Surgeons to an essay of mine on "Wounds and other Injuries of Nerves" in the year 1882. That essay I did not publish, neither did I report any of the cases on which it was founded, for I was not at that time sure of my ground, and felt I had yet much to learn of nerve injuries, and especially of their clinical course. Fortunately for my project I was attached to a large hospital, into which many and various accidents were yearly admitted, and to the surgeons under whose care the patients were placed—yourself amongst the number—I owe a debt of gratitude larger than I can ever expect to pay. Without their constant aid and encouragement, without access to the cases under their care, it would have been impossible for me to have attained my object, or to have had the opportunity of delivering these lectures, much of the material for which has been extracted from an essay by myself, to which the Astley Cooper Prize was awarded last year.

The time at my disposal does not permit me to describe the various anatomical and physiological properties of nerves which bear upon the injuries to which the latter are subject, and I shall therefore at once pass to a consideration of those changes which result from simple section of a nerve trunk, and are seen in both its peripheral and proximal portions. With regard to the peripheral end, there is now tolerable unanimity in one respect at least, as all writers concur in describing a degeneration of both motor and sensory fibres, whilst differing in their description of the process. Waller in 1862 first thoroughly investigated the effects of division, and established the facts—(1) that section of the anterior root, before its junction with the posterior, resulted in a degeneration of that part of the motor fibres which are thereby separated from the cord; (2) that section of the posterior root on the proximal side of its ganglion resulted in a degeneration of that part of the fibres only which intervened between the point of section and the cord, while the periphery of the nerve remained intact. Waller therefore concluded that the ganglion cells of the cord formed a trophic centre for the nerves of the anterior root, while the ganglion on the posterior root fulfilled a similar office for the sensory fibres. These conclusions are generally allowed to be correct, as are also the facts from which the author deduces them, despite the difficulty of explaining the *regeneration* which we shall presently see occurs while the distal end is still separated from its trophic centres. In the above experiments the recurrent nerve fibres present in all nerve trunks may be seen for some time in a normal state in the *peripheral* segment, while in the proximal end of the divided nerve some may be seen in a degenerate condition. The recurrent fibres soon undergo atrophy.

While agreeing in the main as to the changes occurring in the distal end of a divided nerve, the various authors who have investigated this subject differ in the details of the process, and it will therefore be advisable to quote here the most important of these conclusions. Waller and Busch[1] believe that the whole of the primitive fibrils are destroyed, and are regenerated by reunion with the proximal end. Ranvier[2] describes a swelling up of the nuclei of the sheath of Schwann, the protoplasm of which collects into large masses, and encroaches upon the sheath of myeline. The swelling commences within twenty-four hours of division, and by the third day the pressure of the newly formed mass has resulted in a complete section of the axis cylinder opposite the situation of the nucleus in each of Ranvier's nodes. By the sixth day the myeline is reduced to small fragments, the protoplasm contains fatty granules, and the nuclei of the sheath are increased in number. Finally, at the twentieth day the fragments of myeline settle into masses separated from each other by slender filaments with oval nuclei formed by the sheath of Schwann. At the same time granulo-fatty degenerative changes are observed in the connective tissue cells in the endothelium lining the vessels, the fatty granules being probably derived from the myeline which passes in a state of solution through the sheath of Schwann. White blood cells become infiltrated into the substance of the nerve tubes, and appear to be instrumental in removing the débris. Mitchell[3] describes a loss of translucency from the fourth to the sixth day, and says that the white substance of Schwann undergoes an irregular segmentation and finally disappears, the nerve assuming a dull grey tint, like a piece of firm connective tissue. While confessing the difficulty of arriving at a very satisfactory conclusion, he considers that the axis cylinder is probably not affected by the process of degeneration. He does not think that this process spreads gradually from the cut end of the nerve to the periphery, but is satisfied that it affects at one and the same time the whole length of the nerve. Benecke[4] agrees with Mitchell that the degeneration affects the whole periphery simultaneously, and that it becomes of a cloudy yellow tinge and tears easily, the medullary substance coagulates and breaks down to a fine detritus, the axis cylinder becomes enlarged and swollen, and finally disappears, whilst the nuclei of the sheath multiply. MM. Cossy and Dejeune[5] consider that the large nerve fibres do not degenerate so rapidly as the fine primitive fibrils, and that up to the third day the only change is that the axis cylinder is abnormally friable and the nuclei of the sheath swollen. Changes in the medullary sheath, similar to those already described, commence on the fifth day, and are considered by these authors to be secondary to those which occur in the axis cylinder; the latter entirely disappears by the twelfth day. Leegard[6] investigated the condition of the distal ends of the nerves after having produced a simple solution of continuity of the myeline and axis cylinder, and not of the sheath, by the application of a ligature which was immediately removed. He found that in three days the axis cylinder broke up in places, and the myeline ran together in cylindrical masses, and ultimately underwent a granular degeneration, the nuclei enlarged and multiplied, and the axis cylinder finally disappeared from the tenth to the fifteenth day. This process of degeneration attacked the whole peripheral

segment at once. The foregoing conclusions are all drawn from experiments on animals.

In two cases in which I have had the opportunity of examining the nerves of men (one on the fifteenth day after injury and one on the thirtieth) in which operations for the purpose of secondary suture were undertaken, the condition of the peripheral end was very satisfactorily demonstrated after staining in osmic acid. In the case in which the nerve had been divided fifteen days previously there was found much segmentation of myeline, which had collected in droplets of varying size in the nerve sheaths. In most of the sheaths there was some myeline, but in a few it was completely absent. The nuclei of the sheath had increased in number, although not to any great extent. The condition of the axis cylinders was very difficult to establish with certainty. In most parts of the sections they had completely disappeared, and it was only after a very prolonged search that I could satisfy myself that some of them were yet present, though so much altered in contour as to be almost indistinguishable. In the case in which the section was thirty days old the changes mentioned above were all further advanced. Only a few drops of myeline remained; the axis cylinders had entirely disappeared (or at any rate could no longer be distinguished); whilst the nuclei of the sheath were again but slightly increased in number. In another case I examined the peripheral end of a divided nerve three months after section. Here it was impossible to recognise any nerve tubules at all. There was a complete absence of myeline and of axis cylinders. In the nerves which I have examined at times varying from three to six months after injury similar appearances are found. In most of such specimens the places formerly occupied by nerve bundles are marked by the presence of circular masses of tissue which have the appearance of connective tissue with many nuclei. These masses are, however, much smaller than the healthy nerve bundles, and consequently do not fully occupy the spaces in the perineurium, but appear to have shrunk away from the surrounding tissues. My own observations on human nerves would thus appear to accord with those of other observers on the nerves of animals, and it may be concluded that the degenerative changes are signalised by the destruction of the myeline, the multiplication of the nuclei, and the loss of continuity of the axis cylinder. The majority of observers, and amongst them the most trustworthy, are also agreed that these changes occur in the whole length of the peripheral portion at one and the same time, while others maintain that they commence at the cut end and spread downwards, either a short distance from the point of section or else along the whole periphery. This degeneration commences within a day or two of the injury, and within five or six weeks the nerve has undergone complete atrophy.

Central end.—As has already been mentioned, the fibres of the proximal end are comparatively slightly affected by the nerve section. Ranvier describes the changes as being limited to one, or at most two, of the inter-annular segments, and says that the myeline, instead of becoming broken into large fragments, which subsequently become smaller, as in the peripheral end, is rapidly reduced into fine granules, which later on assume a yellowish-brown colour with osmic acid. The nuclei multiply and increase in size, but instead of encroaching on the medulla they remain flattened against the sheath of Schwann, whilst the axis cylinder remains intact. An infiltration of white blood-cells into the myeline occurs, resembling that already described in the peripheral segment. Neumann also describes somewhat similar changes. Leegard[7] describes changes like those which he noticed in the peripheral end as occurring in the first inter-annular segment of the proximal end; the next three or four segments become also irregular and shorter, with the medulla broken up. The sheath is empty at places, and shows nuclear prolification.

Bulbs.—It is now many years since it was noticed that after section of a nerve the upper end became bulbous, and this has more particularly excited observation in stumps. The very general opinion as to the structure of these tumour-like swellings in the nerves is that they consist of fibrous tissue, a statement which has been handed down from one author to another without apparent investigation. George Hayem in 1877[8] was the first to point out that these bulbs consist not only of newly formed fibrous tissue, but also of new nerve elements. He believes that after section the most distal portion of the upper end degenerates, and is replaced by young fibres which undergo a gradual process of development. In a case which I have recently examined, the amputation (through the leg) had been performed five years previously in a lad aged twelve years. Reamputation became necessary on account of an insufficient covering for the bones, and an examination of the bulb on the anterior tibial nerve showed on cross section a greater number of fibres than did the healthy nerve above. The only conclusion that can be arrived at is that the additional fibres were of new formation; they were mixed with newly formed fibrous tissue. A microscopic examination of such a bulb under a low power shows a proliferation of the perineurium, which penetrates between the different fibres in the bundles, and separates them into smaller bundles of three, four, or more fibres. Later on, these fibres becoming compressed, gradually lose their sheath of myeline, and so appear smaller than normal, until finally they come to be composed only of axis cylinders. The lower down in the bulb the section is made, the more complete do these changes appear; so that between this part and the junction of the bulb with the healthy nerve above all stages of transition between connective tissue and healthy fibres may be seen. Considering that the young nerve fibres also appear on section to be smaller than normal, it becomes very difficult to say for certain whether any individual nerve tube is in a stage of transition into a higher or lower state. Nevertheless, as a transverse section shows, on careful examination, that although some of the thickness of the bulb is due to an increase of the connective tissue elements, yet the larger amount of it is composed of nerve fibres, we are naturally driven to the conclusion that some of these must be of new formation. Sections of the nerve trunk above the bulb do not usually show any of the degenerative changes that are met with in the peripheral end, there being no increase of connective tissue or decrease in the white substance of Schwann unless inflammatory changes have been started and "chronic neuritis" has supervened. In those cases, however, where the section is of very long standing, it appears that after the lapse of a considerable time, probably years, the nerve fibres do in part atrophy and degenerate, and thus follow the example of other tissues and bear evidence to the general truth of the pathological law that "atrophy results from non-use." I have not myself had opportunities of examining the proximal ends of divided nerves at any distance from the seat of injury after simple section, but I have examined the nerves from limbs in which amputations have been performed in bygone years, and have found in them that many of the nerve fibres are diminished in size, that their myeline sheath is greatly shrunken, and that some of them have quite disappeared. This is a pathological fact of the greatest clinical interest, and one to which I shall again have occasion to refer.

Regeneration and union.—The process of degeneration, which has just been described, is succeeded by one of regeneration, resulting, in favourable cases, in a complete restoration of the nerve. It is of great importance to observe that this regeneration *can* take place in the peripheral end previous to any reunion with the proximal extremity, and an examination of the former several months after section will show that some of the axis cylinders have been re-formed, and that around them a deposit of myeline is slowly developing. The fibres are not, of course, collected into symmetrical bundles, as in a healthy trunk, and are smaller than natural; they may be seen scattered about amongst the surrounding connective tissue in all stages of development, some of the axis cylinders yet naked, others with varying amounts of myeline around them. It seems strange that such regeneration should take place without reunion with the nutritive centre, but the importance of the fact for a proper appreciation of the symptoms and results of nerve sections, as well as for the light it throws on the question of treatment, makes it one of much interest. As to the exact process by which these new nerve fibres are formed and the divided ends reunited, time does not permit me to do more than refer very briefly to the opinions and work of others. As a result of experiments on various animals, it has been shown by numerous writers that the nuclei of the sheath are the chief agents in the repair, and that they form new axis cylinders and unite the divided ends. The description by Ranvier of an extension of the axis cylinders of the upper end into the [illegible] of the peripheral portion is not generally [illegible]

already alluded to my own examinations of human nerves in a state of degeneration, and shall now describe the appearances I have met with in cases in which regeneration of the peripheral end had occurred after section, independently of union with the upper portion.

The first case was that of a lad, aged eighteen, in whom an operation for reunion of a divided ulnar nerve was undertaken seven months after injury. An examination of the portion of the peripheral end, which was removed preparatory to suture, showed that, scattered throughout a transverse section, were several small, imperfectly developed nerve fibres such as are met with (and have already been described) in the bulbous proximal end. These new fibres were not collected into definite bundles; they were much smaller than natural, and their myeline sheath was scarcely perceptible. The total number of these new fibres was but small, and I was unable to trace their development in a satisfactory manner.

The second case was that of a woman, aged fifty-three, who had divided the median nerve just above the wrist-joint. An operation for suture was undertaken nine months later, and the condition of the resected portion of the peripheral end was found to be as follows. The circular spaces in the neurilemma, which, in a state of degeneration, I had previously found in other cases and have already described as partly filled with nucleated connective tissue, I now found to be occupied by nerve fibres, in varying stages of regeneration. The steps in the formation of these fibres could, moreover, be most clearly traced. Their first appearance was in the form of oval and spindle-shaped nuclei, which seemed to be identical in structure with the nuclei of the sheath. These nuclei were arranged in bundles, with their long axes parallel to that of the nerve trunk. The next step was the elongation of the nuclei and their gradual transformation into fibres, around which subsequently a myeline sheath was formed. In some parts of the section, bundles of newly formed nerve fibrils could be seen occupying the spaces in the neurilemma which had evidently been previously occupied by the healthy nerve bundles, before the time when the injury was inflicted. The new fibres in some bundles were in a much more advanced stage of development than those in others, the regeneration appearing to progress simultaneously throughout all the tubules in each bundle irrespective of the condition of the fibres in others.

I have also had the opportunity of examining the nerve ends in a case in which the ulnar had been divided nearly two years before I saw the patient. The nerve had been completely cut across, and no union had taken place, the upper and lower ends being separated by about half an inch or more of firm cicatricial tissue. A microscopical examination of the peripheral end showed that many of the fibres had been regenerated. A large number of the bundles contained numerous nerve fibres in various stages of development. In some the axis cylinder alone was formed. In many others the myeline sheath surrounded the young axis cylinders, whilst in some the "nodes of Ranvier" were well marked.

There is, indeed, a tolerable consensus of opinion as to the part played by the nuclei of the sheath, from which, according to most authors, the new axis cylinders are formed. The strongest objection to Ranvier's theory, that the undegenerate fibres of the central end grow into the empty sheath of the periphery, lies in the fact that, as I have already described, the peripheral end will regenerate even when ununited to the central healthy fibres; and if further proof of this be necessary, it may be found in the investigations of Phillippeaux and Vulpian,[9] who not only saw regeneration of the peripheral fibres without union with the proximal end, but found the same take place in a piece of nerve resected and transplanted into the surrounding tissues. If, then, the peripheral end has become regenerated, and is placed in sufficiently close proximity to the central portion, union will result by the continued formation of nerve fibres between the divided extremities. But, on the other hand, should union fail, it appears probable that the nerve again degenerates, perhaps never to recover. I have found no mention of this by other authors, but am, nevertheless, inclined to feel certain that such changes must occur, for otherwise we should have some difficulty in explaining those cases in which many years after injury the nerves have been found completely atrophied. As examples of such I append the following two cases. Israel[10] records the case of a man who had been shot through the median and ulnar nerves thirty-two years previously. The peripheral ends were found to have only the thickness of a knitting-needle, and to consist chiefly of connective tissue. In vol. xxiv. of the Pathological Society's Transactions, Mr. Butlin describes a case in which the ulnar nerve had been divided fourteen years before death. No union had taken place, and the lower end was found to consist nearly entirely of connective tissue, a microscopic section showing that the healthy nerve fibres had entirely disappeared, while the presence of any axis cylinders was very doubtful. No doubt many such cases can be found, and all bear but one of two explanations. Either the divided nerve never became regenerated at all, or else it subsequently again degenerated. The latter appears to me the most likely, but before the matter can be considered settled more investigation is necessary.

The conclusions which may be drawn from the most recent investigations are: 1. That the nuclei of the sheath of Schwann (which are developed from epiblast) form the new axis cylinder. 2. That the myeline is subsequently formed around the new cylinder. 3. That the peripheral end may become in part regenerated without forming any union with the proximal extremity, but that it probably again tends to degenerate if union fails.

(To be concluded.)

ABSTRACT OF

Lumleian Lectures

ON THE PATHOLOGY OF INTRA-UTERINE DEATH.

Delivered at the Royal College of Physicians of London, March, 1887,

BY W. O. PRIESTLEY, M.D., F.R.C.P., LL.D.,

CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL, AND LATE PROFESSOR OF OBSTETRIC MEDICINE, KING'S COLLEGE.

LECTURE III.

DR. PRIESTLEY in this lecture discussed the diseases and anomalies of the placenta, one of the chief difficulties in the study of which arose, he observed, from the tendency on the part of authors to regard the particular morbid change which they have had the opportunity of investigating as the chief or only disease with which the organ is affected. All other morbid appearances are for them but consequences or complications of a specific and cardinal lesion upon which the rest depend. Thus Charpentier accepts the investigations of Robin as illustrating the whole range of placental pathology, and believes that when disease has invaded the placenta it commences always in fibro-fatty change; and consequent on this, blood extravasations and successive transformations of effused blood account for all the various pathological appearances associated with the death or enfeebling of the fœtus. Verdier and Bustamente, on the other hand, take entirely another view of these changes. To the lecturer it appeared that one cannot long investigate the diseases of the placenta without discovering that they are most complex in their nature, and that they proceed from a variety of causes inextricably intermixed—sometimes one pathological condition having the precedence, sometimes another. The placenta is, in truth, as liable to be affected by a variety of diseases as the liver or the lung, and some of its diseases bear not only a striking resemblance to diseases occurring in those organs, but have affinities with them and may depend on the same causes. Confusion has also arisen from investigators describing the same morbid condition under a different name, probably because it was observed only in one stage of progress or with some variations; and some have fallen into the error of ranging affections which are intrinsically different under the same appellations. Extravasations of blood into the young placenta are very common, and they occur as the result of rupture of some of the vascular maternal loops which ramify throughout the placental mass and surround the villi of the chorion. These vascular maternal loops eventually become the sinuses or

Digitized by Google

cavities which permeate the placental tissue at a later period. If the extravasations be limited in extent, the life of the embryo may not be compromised, but a more extended apoplexy at once stops its nutrition, and the root-like processes of the young villi become so compressed that the circulation can no longer be carried on through the minute fœtal bloodvessels which they contain. Apoplexy takes place into the substance and on the uterine surface of the full-grown placenta also very frequently. There is, however, this marked difference from the earlier period—that now the placenta is larger and thicker, and isolated clots may be deeply embedded in its substance, only to be exposed by incision. Others may have been formed between the uterine walls and the maternal surface of the placenta, making a deep depression into the centre of a placental cotyledon and compressing the placental structures. As a further difference in the results of blood extravasations in the young and more mature placenta, Dr. Priestley pointed out that in the latter several successive effusions of blood may take place, forming apoplexies of varying sizes and dates, without so seriously jeopardising the life of the fœtus as it would do at an earlier period of gestation. The larger size of the placenta and its more extended surface afford a better chance of so much of the potential part of it retaining its healthy relations, and so carrying on the placento-fœtal circulation that embryonic life is sustained. Among the writers on this disease are Sir James Simpson, M. Jacquemier, Verdier, Bustamente, and Robin. The last named differs *in toto* from other workers in the same field as to the order of pathological events in the placenta. He insists that no blood extravasations take place in the placenta without previous disease in the tissue, and that the morbid change which is the most common forerunner of apoplexy is not mere vascular change, but an alteration of the whole structure of the villus. The interference with the life of the child or with the course of gestation depends upon the amount of extravasation, and the excitability or quiescence of the uterine walls under the provocation to contraction.

Inflammation of the placenta, or placentitis, has been discussed by several authors, amongst whom Simpson described it as consisting of three stages: the first being one of congestion, in which the tissue is engorged by an unusual accumulation of blood in the vessels; the second characterised by the exudation of coagulable lymph, producing a greater density of tissue and eventual induration; the third stage being that in which purulent matter is formed. In later days a good deal of scepticism has been expressed about the existence of placentitis—at least, so far as its parenchyma or fœtal portion is concerned. Bustamente disbelieves in its existence altogether, and says the evidence rests on the supposed presence of pus, which has been shown to be fallacious; the supposed purulent matter, according to Robin and other observers, being merely pseudo-pus, produced by broken-down fibrin. It has been further argued that, according to modern theories, inflammation of the placenta is impossible, since there are no capillaries in the maternal portion, and there are no nerves to regulate the contractility of vascular walls in the entire structure. This reasoning does not, however, seem conclusive to Dr. Priestley. There are fœtal capillary loops in all the active villi, and there are also minute capillaries of maternal origin in processes or dissepiments of the decidua which circumscribe the fœtal villi. It is true, nevertheless, that the presence of purulent matter in the placenta in most of the reported cases is supported by imperfect evidence. There are only some ten cases of abscess in the placenta recorded, and as no account is given of the microscopic examination of the supposed pus, the evidence is plainly unsatisfactory. Purulent matter has, however, been found and duly authenticated on the surface of the placenta and in the uterine sinuses at or near the placental site. That some morbid change analogous to inflammation does take place in the placenta or its neighbourhood is apparently indicated by the firm adhesions which are occasionally formed between the placenta and the uterine walls, and from the traces of an exudation which agglutinates and compresses the villi of the placenta.

Dr. Priestley then spoke of a remarkable affection which he designated as placental phthisis, a disease which repeated investigations have convinced him is not, primarily at least, a mere increase of the cell structure or of the fibroid element in the placenta, but in its first stage consists of an exudation or deposit thrown out among the villi, and is probably due to some modification of a low inflammatory process. The disease is not really tubercular in its character; nor have bacilli been found in its substance; neither is it primarily or essentially a fatty degeneration, for the deposit is not affected by the reagents which show the presence of fat. Its corpuscles, unlike fat-granules, are thoroughly coloured by the material used for staining the microscopic sections. It is not due to changed blood clot, for there are neither altered blood-corpuscles nor crystals in its substance. Its general appearance, both before and after section in the earlier phases, is rather that which has been described as fibrinous or other analogous deposit, and it has the chemical characters of protein compounds. Dr. Priestley announced his intention of going into the minute pathological anatomy of this so-called placental phthisis in a paper which he purposes offering to the Obstetrical Society. In the order of successive changes the disease runs in somewhat parallel lines with phthisis in the lungs. First comes solidification, then softening, with breaking up of tissue and resulting hæmorrhage. A notable feature in many of the microscopic sections was the great hypertrophy of the contractile coat of the fœtal bloodvessels. It is not an uncommon form of disease, and there is some reason to believe that although commonly it runs a chronic course, yet occasionally its progress is very rapid. With regard to fatty degeneration of the placenta, the lecturer remarked that the question is whether this disease during the life of the child really occurs as a primary pathological change, or is invariably preceded by some exudation or other morbid change which initiates the fatty metamorphosis. Fatty degeneration, whether it occurs as a primary change or is the secondary effect of some other pathological condition which precedes it, may produce softening and disorganisation of the placental tissue, and so favour extravasation of blood or apoplexy. In other placentæ it leads to atrophy. Virchow has described a very curious morbid transformation of the villi of the placenta, which he terms "myxoma fibrosum." It consists of such enlargement of the stems and villi by fibroid hypertrophy that they form in some cases distinct tumours in the placental structure. Cases of this disease are somewhat rare; but Dr. Priestley has seen two excellent examples in Copenhagen, which have been described in Virchow's *Archiv*, in 1878, by Storch. Virchow regards the disease as a transformation of the mucous element pertaining to the villus structure into fibroid tissue, instead of the soft myxoma which is seen in cystic chorion. The fibroid change is, however, unlike the cystic chorion, more frequently connected with the later period of pregnancy, although indications of it are sometimes seen in the earlier months.

Passing over œdema of the placenta, melanosis, calcareous or osseous concretions, cysts and tumours, Dr. Priestley then came to the subject of syphilitic placenta, concerning which much diversity of opinion exists. So far as his observation goes, he does not think we are yet able to say with precision that any one specific lesion of the placenta belongs alone to syphilis, although some morbid appearances are more constant than others in connexion with syphilis—as, for example, the changes described by Fränkel. In addition to the hypertrophy of the villi described by Fränkel, and morbid changes in the decidua, he had seen fibroid deposits, such as those described by Rokitansky—some unchanged, others undergoing fatty transformation. Again, he had seen the yellowish granulations of varying sizes looking like tubercles, as observed by Lebert; but he had also seen most, if not all, of these pathological appearances where no syphilitic history could be traced. The nearest approach to precision in this respect is to say, as a general rule, when the decidual or maternal portion of the placenta has become so far changed by hyperplasia as to arrest the utero-placental circulation and the full development of the placental villi, that this is probably due to maternal syphilis. It finds its analogy in the changes which take place in the mucous membrane in the uterus and elsewhere when the blood is undoubtedly poisoned by syphilis, and also in the thickening of the decidua during the early pregnancy of syphilitic women, which has been described by Virchow and Dohrn as "endometritis papulosa et tuberosa." When fibrinous and pseudo-tubercular deposits are found in the placenta in connexion with syphilis, they are probably only the expression of a depraved or impoverished condition of the blood, which may be equally associated with anæmia or with some form of dyscrasia. When there is marked hypertrophy and degeneration of the villi, the maternal portion of the placenta being less affected, the syphilitic taint more probably comes from the male parent, and the mother may show no signs of

Digitized by Google

the disease. Both Depaul and Tarnier, among modern observers, dispute the existence of absolutely specific lesions in the placenta as the result of syphilis. De Sinéty, one of the latest writers quoted by Charpentier, did not find placental lesions in all women affected with syphilis, but where lesions were present he was able to demonstrate three important points: (1) hypertrophy of the placental villi; (2) fibrous degeneration of them; (3) islands of granulation belonging to the caseous forms of degeneration. This coincidence of the fibrous and caseous forms of degeneration is found in syphilitic gumma, notably in gummata of the liver. De Sinéty had not found this combined degeneration except in syphilis. He does not know if any other disease may produce the combined changes, and does not decide the question as to a specific placental lesion in connexion with syphilis. In reference to all diseases which affect the placenta, it is to be noted that the effect on the life of the child bears a direct relation to the amount of damage done to its tissues, and impairing its double function as an organ for respiration and absorption. In cases of separation of the placenta, a portion still adherent to the uterine walls may be enough to sustain the life of the child, for a time at least; and, in like manner, when the placenta has become diseased, if some portions of it only remain sound, vitality may still be maintained in the body of the fœtus. If the morbid process be slow and chronic, there will probably be progressive emaciation; and if the child be born alive, it will have all the appearances of being starved during its development. If the placental disease is more acute and rapid, and affecting a large area of tissue, the child's movements become at first more restless than usual, and then become less marked and distinct as they subside into absolute quiescence. With the aid of the stethoscope the beats of the fœtal heart have repeatedly been noted in cases of suspected placental disease to become slower and slower, and thus to furnish important indications for the induction of premature labour. Among the further causes of fœtal death in utero which Dr. Priestley said he could not in these lectures overtake are the pathological conditions of the umbilical cord, antepartum hæmorrhage, extra-uterine gestation, and allied conditions, the malformations and diseases of the unborn child—the most fertile cause of the latter probably being syphilis. Time, also, did not permit him to speak of the changes taking place in the body of the fœtus when it is long retained in the uterus after its death; of the inferences to be drawn as to the cause of death from the appearances it presents after longer or shorter periods of retention; and other kindred topics.

With regard to the subject of preventive treatment, Dr. Priestley stated that, so far as obviating some of the forms of intra-uterine death is concerned, we are absolutely in the dark, and the therapeutics of the subject are still a closed book. Still, a careful study of the several pathological conditions in the parents, combined with the local expression of the results of these conditions, allows in some cases of methods of treatment being formulated and of rules for guidance being laid down which in practice have been attended with happy results. Whenever, therefore, a woman has once or more frequently lost the product of conception at an early or later period, careful inquiry should be made into the health of both parents, and any previous history of illness should be accurately scrutinised. No pains must be spared to ascertain whether syphilis is at the root of the misadventures. When either parent has, in the near or distant past, contracted this disease, both should at once be put under anti-syphilitic treatment before a fresh conception is permitted, and this ought to be sufficiently prolonged to give it a fair chance of producing satisfactory results. Dr. Priestley said that he had repeatedly seen good effects from small doses of bichloride of mercury, with bark, given during the first three months of gestation, when there has been no opportunity of commencing the treatment before conception began. Similar favourable results have been observed to follow the administration of iodide of potassium. If inquiry shows that the health of either parent is disordered or deranged from some other cause than syphilis, care must be taken to trace out the nature of the deviation from health, and so to define it that treatment fulfils its purpose. Not the mother only, but the father also, must be put under supervision. Any constitutional peculiarity or diathesis must be met by appropriate means—the strumous, by tonics and cod-liver oil, with such improved climatic conditions as may be feasible; the gouty rheumatic by limitations of diet, careful regimen, and alkaline medicines. Keeping the bowels of women who are liable to abortion unloaded by aperients is important. Such laxatives as are not likely to stimulate undue action of the bowels or straining must be chosen, else the medicines may stir up the very mischief they are given to prevent. Compounds of sulphur, the confection of senna, and saline aperients seem best to fulfil the needful indications. The advantages of general bloodletting are doubtful, and its employment may lead to harm instead of good; but local depletion by leeches is less objectionable. For anæmia, preparations of iron must be administered in some form least likely to disturb the digestive organs of the patient, and these should be given not only antecedent to the occurrence of conception, but continued with such modifications and in such combinations as may be suitable during the progress of pregnancy. Where local conditions have been ascertained or suspected to be the cause of repeated abortion or of later fœtal death, the treatment must be directed in accordance with the special requirements of the case. Especial care should be taken to remove as far as possible all indications of endometritis prior to the commencement of pregnancy, an unhealthy condition of the lining membrane of the uterus being regarded by most authorities as a potent cause of disease in the fœtal membranes and placenta. Rest in the recumbent position is important, especially at the times which correspond to the days of the catamenial period, and all forms of locomotion likely to jar the body must be sedulously avoided. Chlorate of potash, Dr. Priestley thinks, may act usefully as an alkaline salt in preventing the formation of coagula and fibrinous deposits in the placenta. In instances where the progress of zymotic disease or of inflammation in some organ of the patient's body is attended with high temperature, he suggested that an attempt should be made to lower the temperature of the uterus and of the fœtus either by the application of ice-bags to the maternal abdomen, or of those tubular appliances for the application of cold which may be modified to fit any part of the body. Some of the baths and waters on the Continent have a high reputation for their tonic properties and their favourable influence on pregnancy. Aix-les-Baines is said to be useful in these cases. Courses at Schwalbach and Kissingen have been followed by happy results. The former place is more appropriate for patients who are more or less anæmic, Kissingen for those in whom the digestion and portal system are at fault.

ON THE USE OF THE

THERMOPILE AND SECONDARY BATTERIES AS A CONVENIENT MEANS OF PRODUCING ELECTRICITY FOR MEDICAL AND SURGICAL BATTERIES.

BY ALEX. OGSTON, C.M.,
PROFESSOR OF SURGERY, UNIVERSITY OF ABERDEEN.

ELECTRICITY has never played so important a part in the routine of daily practice and consulting-room work as its undoubted usefulness would seem to indicate that it should. In comparing it, for instance, with the stethoscope and thermometer, we find that, while these are in the hands of every physician and surgeon, electricity is hardly met with at work, save in the chambers of a few specialists and in a few well-equipped hospitals. Many common mechanical instruments for studying and treating disease—such as the measuring line, the weighing machine, the concave reflecting mirror, and the speculum—are regularly employed by the majority of practitioners; while electricity, despite its value in the diagnosis and treatment of nervous disease, as an unsurpassed illuminating agent, as an electrolytic destroyer of diseased tissues, tumours, and nævi, as the most manageable cauterising agent, and as supplying the electromagnet for extracting fragments of iron from the eyeball, is superseded for these purposes by less efficient means. The expense of electrical apparatus, and the want of knowledge concerning it, are not the chief reasons for this neglect. The explanation is to be found in the extreme inconvenience attendant upon the methods of generating electricity at present employed. Not to mention, then, the initial cost of procuring a good combined battery, capable of furnishing both continuous and

Digitized by Google

induced currents, and without dwelling on the fact that when procured it is unsuitable for the electric cautery, everyone who employs it must be painfully impressed with the constant trouble and time expended in keeping it in order. The zinc plates have to be amalgamated, the acids to be prepared and introduced beforehand, and the corroded connexions gone minutely over and rectified before the battery is used. During its employment difficulties may arise from polarisation and other causes, although in the bichromate batteries the polarisation difficulty has been pretty well overcome. After the battery has been used, and in all likelihood for a few minutes only, the emptying and cleaning of the cells have to be gone through, and perhaps a couple of hours spent in this before it is laid aside. Even then the remains of acid and the resulting galvanic action corrode the brass work and connexions, and it is uncertain whether it may not require before next it is used a prolonged visit to the electrical mechanician's workshop. It is, I think, a fair estimate to say that, when used by the ordinary practitioner of medicine and surgery, each employment of the battery involves three or four hours of work, by far too great an expenditure of that valuable time which to him more than most means money. Nor do the objections named exhaust the inconveniences that are urged against the batteries. Bottles of acids are difficult to keep, stoppers become fixed, and the bottles are broken in their hurried removal, the waste acids are inconvenient to be got rid of, and, above all, no acid battery in ordinary use is in the least suited for the requirements of transport. We are to-day much where we were twenty years ago as regards these inconveniences. The Leclanché batteries are too bulky, and, being weak, too many cells are required, so that, like most others, they are quite unsuited for transport. The Gaiffe batteries are not easily recharged, and in practice have been found unsuitable. The only really convenient appliance for transport—the magneto-electric induction machine—is useful only as an exciter of faradaic muscular contractions.

I wish to direct the attention of the profession to a method by which electricity in all its forms can be readily and easily obtained at all times, by arrangements that are easily and conveniently managed, that are little liable to get out of order, that can be procured at a moderate initial expense, and cost little or nothing afterwards, that are convenient for transport, and are in all respects attended with the minimum of inconvenience. I do not claim that the arrangement I advocate the adoption of is all we could wish it to be, but believe it is a very great step indeed in advance of the plans hitherto proposed, and is likely to satisfy a large number whose employment of electricity in practice is at present hampered or prevented by the drawbacks that have been mentioned. The plan is not my own. It was suggested to me last year by Mr. J. W. Swan, the well-known inventor of the incandescent lamp that bears his name. He pointed out to me that the employment of the thermopile as a generator of electricity would probably be of considerable service to members of our profession, and he was good enough to interest himself in the matter and work out for me, in a manner I could not myself have accomplished, the practical steps towards effecting this. I explained to him our wants, and he devised the means of meeting them. The thermopile, which forms the starting-point of the arrangement, is composed of four groups of German-silver and zinc-antimony elements, each group containing twenty pairs in the form of a wheel, six inches and a half in diameter, in which the elements are the spokes. The four coronal groups are placed on a wooden stand, about sixteen inches square, and are connected together in series—i.e., the positive pole of one group is attached to the negative of the next. Each group has in its centre a gas Bunsen burner, the burners all supplied by a common pipe, but with taps so placed that they may be used separately if required; and when the burners are lit, the difference of temperature between the outer and inner ends of the pairs of elements generates a current of electricity, feeble indeed, but very convenient, since its feebleness can be compensated for, and its convenience, requiring as it does only the turning on and lighting of the gas, is unquestionable. These thermopiles are made by Rebicek of Prague. They give an electro-motive force of about one-tenth of a volt per pair of elements—that is, four volts for the four groups, equal, say, to seven or eight Daniell's and three or four Grove's cells, power sufficient to illuminate a small incandescent lamp. A slight alteration in the thermopile would adapt it for being used with spirits of wine, or even with paraffin. Several of these thermopiles can be arranged in series, with a gain in electro-motive force corresponding to the increase in the number of elements added, but at the cost of an increase in initial expense, and, from their bulk, a lessening of convenience. Were they to come into general use, their bulk could be considerably reduced by some slight alterations.

The thermopile alone, however, is insufficient for the purposes of the practitioner. To render it useful it requires to be supplemented by the secondary battery, or accumulator, as it is sometimes called. With this addition in a suitable form, portability being the chief point, the apparatus is complete. The secondary batteries which Mr. Swan designed for me for this purpose, consist of two portable vulcanite boxes, each three inches square and eight inches high. Each box contains two cells arranged on the principle of Planté, with elements of lead and peroxide of lead, in dilute sulphuric acid of 1 to 10 in strength. Each is closed by an indiarubber washer and a lid clamped on by a screw, to prevent their spilling when carried, a ring-handle being attached for this purpose. They can, like ordinary galvanic cells, be used separately or in conjunction. Each weighs, when filled and charged, 6 lb. 1 oz. Mr. Swan writes concerning them:—"The object in dividing the batteries is that there may be no unnecessary weight to carry where the power of one battery (two cells) is sufficient, and it will be sufficient for surgical lamps for eye and throat examination. For electrical cautery the combination of the two batteries is needed. The thermopile has just power enough to charge one battery at a time when the gas is not very fully turned on—that is, when the flame just burns above the talc disc. Under these conditions the thermopile will send ½ or 0·6 of an ampère through one of the batteries, and that is what is proper for a battery of this size. While charging, the cover should be removed, and several folds of blotting-paper laid on the mouth of the battery to intercept the bubbles of gas that rise from the liquid. It is necessary to make up for this loss of liquid by adding to that in the cells sufficient to cover the plates. The battery should not be allowed to become completely discharged, and, after using, it should, as soon as possible, be fully recharged and left so. The only part of the battery likely to get out of order is the connexion between the positive plate and the outside terminal, but it is very easy to repair, and I think probably little or nothing beyond that will require to be done to the batteries for a long time. Several folds of blotting-paper round the joint of the lid and case, or a waterproof bag to contain the whole, will prevent driblets of acid staining the clothes of the person carrying it."

In using these cells I have not found any drawback to them, save the slight one mentioned by Mr. Swan—viz., an occasional tear of acid pressed out when they are used, closed, or carried, by the pressure of the accumulating gas within. On the contrary, they are among the least obnoxious occupants of my work-room. They stand on a table in a porcelain photographer's tray or common plate beside the thermopile, for the convenience of charging. The tops are removed, because, if they are kept screwed on, the imprisoned gas that is disengaged forces out a few drops of liquid past the washer, and this trickles down; while if they are removed no spilling occurs, and they remain dry and clean. When about to be transported, the lids are screwed on, blotting-paper is put round their upper ends to catch any tear of acid, and, thus arranged, they can be carried about a whole day with perfect convenience. If the liquid in the cells diminishes, a few drops of dilute acid are added by a pipette. After they have been used for any length of time, the thermopile is lit, its conductors are connected with one of the batteries at a time, and in a few hours it is completely recharged, as may be seen by the free escape of gas from the plates. The cells are connected at will with two pairs of insulated cord conductors that pass along the wall and through the partition into the consulting-room. The two pairs of conductors enable the batteries to be used simultaneously for different purposes, one being attached to each pair, or to be both connected with one pair as desired.

I have during the past two months subjected the arrangement to the severest tests of practice, having used it for nearly every purpose save that of extracting steel by the electro-magnet, and have every cause to be satisfied. The batteries yield a sufficient constant current, can be attached to the induction coil for faradisation, answer well for electrolysis, and are very convenient for illuminating the mouth and examining for translucency in cystic tumours. They

Digitized by Google

are very efficient for the galvano-cautery, easily heating, when fully charged, three or four inches of stout platinum wire white hot, and fusing thinner pieces. When employed for electric illumination in the work-room, the conductors from one battery are connected with a two-candle power Swan lamp placed in the hollow end of a piece of bamboo, which shades the eyes of the observer from the light, and, acting as a handle, enables it to be directed towards the part to be illuminated or introduced into the mouth. When both batteries are attached I can light up my consulting-room by means of a five-candle lamp that is suspended by a bracket from the wall. In testing the translucency of cystic tumours, the two-candle lamp in its bamboo handle is pressed against one side of the cyst, and, the swelling being shaded by the hand, the other side of the tumour is observed. In cases of hydrocele of the tunica vaginalis, and in one case of congenital cystic hygroma of the neck, the translucency was well brought out, and it is much more convenient than the candle or wax taper, especially in children, whose incautious movements cause danger of scorching them. In the use of the endoscope the greatest inconvenience is felt from the heat of the lamps used in connexion with them, and from the necessity of keeping them upright. This inconvenience is a very great drawback indeed to its employment in examination of the œsophagus, the rectum, and especially the urethra, where it is occasionally of the greatest service. The introduction of a two-candle power Swan lamp into the instrument creates quite a revolution in this respect, and converts the endoscope from a very cumbrous into a most manageable aid to diagnosis. When required for faradisation the conductors are simply attached to the coil standing in the consulting-room. Both batteries have to be attached to the conductors for electrolysis, electric cautery, or the use of the constant current. In galvano-puncture I have not yet had an opportunity of using them, but in electrolysis they answer well, one needle being attached to each conductor. For electro-cautery or the galvanic écraseur the instrument is attached to the conductors and the circuit completed at the moment desired by the button being closed. I was pleased with its action in cauterising the pharynx, and in burning a small canal that had to be closed after an extensive operation for cleft of hard and soft palates. In using the constant current a sponge electrode is affixed to each terminal of the pair of conductors. The method of attachment most convenient is that of a pin slipping into a tube or socket, which is quickly connected or undone, or, when needles are used, joining them to the conductors by a thin bit of silvered copper wire.

During the two months in which I have employed the above arrangement, it has been in almost daily use, and its efficiency has been tested in every way; yet the secondary batteries have only thrice required to be charged by lighting the thermopile for a few hours. The convenience of the whole, and its superiority to any of the methods hitherto suggested, are so very striking, that I unhesitatingly recommend it to the notice of my professional brethren in the very strongest terms.

Note.—The price of the thermopile is about £8; each of the secondary batteries costs 55*s*. They can be had through the firm of Mawson and Swan, Mosley-street, Newcastle.

CASE OF INTESTINAL OBSTRUCTION FROM IMPACTION OF A GALL-STONE IN THE ILEUM.

ABDOMINAL SECTION AND REMOVAL OF THE STONE; DEATH ON THE SECOND DAY.[1]

BY BRYAN HOLME ALLEN, M.D. LOND.

I WAS called to Mr. C. E., aged fifty-seven, on Sept. 20th, 1886, on account of constant sickness followed by faintness. On inquiry I obtained the following history: He had enjoyed fairly good health, but had had an attack of typhoid fever twenty-eight years ago. He was always disposed to be constipated, but by the free use of aperient medicine had kept his bowels acting. He had been a somewhat free liver, and for the last few years had suffered from business anxieties. On July 14th of this year (1886) he was seized with severe vomiting and acute pain in the epigastrium and right hypochondrium, followed by jaundice; the pain was intense for three or four days; the urine high coloured. I could obtain no definite information about the motions; he was supposed to have passed a gall-stone, though nothing was ever seen in the motions. In a month's time he returned to business, feeling fairly well, but not losing the sense of uneasiness in the right hypochondrium. His bowels were more obstinate than ever, acting for the last time on Sept. 13th. On the same day he was seized with frequent vomiting of green bilious matter. On the 17th he consulted a physician in London, who carefully examined him, and, finding nothing in the abdomen, attributed the vomiting to gastric catarrh, and advised him to come to Hastings, which he did on the 20th. On that day I found him complaining of great faintness, and of some pain in the stomach, mostly at the epigastrium, but to a less degree in the region of the cæcum and descending colon, with moderate tenderness in these latter regions. He was vomiting frequently, the vomited matter being very green, of an acid, disagreeable, but not at all feculent smell. His bowels had not acted for a week, nor had he passed flatus per anum. No tumour or special resistance could be anywhere felt in the abdomen. There was no abdominal distension, and no visible movement of the coils of intestine. The pulse was large, soft, and quick. He was sent to bed, moderate doses of opium administered, and an injection ordered, which failed of effect, probably from imperfect administration. On Sept. 21st, 22nd, and 23rd he had an injection each day of three or four pints of soap-and-water, which on each occasion brought away some green offensive, solid, but not hard, lumps, after which the abdominal tenderness disappeared and the pain and sickness greatly diminished, the character of the vomited matter remaining unchanged. He was taking ten minims each of the solution of morphia and tincture of belladonna every four hours, or oftener if required. His diet consisted of half a pint of milk and a little beef-tea in twenty-four hours; a beef-tea enema was given every four hours. On the 24th he was ordered a five-grain cathartic pill (U. S. Pharm.) at bedtime, followed in the morning by an injection through a long flexible tube. On the 25th two pills of the same were given, also followed by an injection, which brought away motions of the same character as before. The vomiting varied from once to three times in the twenty-four hours, but was becoming more distinctly unpleasant. Very little pain; no tenderness or distension; no wind passed per anum. On the 26th and 27th the injections were repeated, but no action followed, and on the evening of the latter day the vomiting was distinctly feculent. There was no distension of the abdomen. On the 28th Dr. Arthur Gamgee saw him with me, and suggested the employment of electricity. Chloroform was given, and a current from a large primary coil was used, being passed from one side of the abdomen to the other, and afterwards through the rectum, but although violent action of the abdominal muscles was produced, no other effect resulted. Nothing definite could be felt in the abdomen under chloroform, but Dr. Gamgee thought that he felt greater resistance in the region of the ascending colon.

The intestinal obstruction had now been complete for sixteen days. Some fæcal matter had been brought away by the injections, but this evidently came from below the obstruction. No flatus had been passed since Sept. 13th, when the symptoms of obstruction set in. After careful consideration of the symptoms, I now came to the conclusion that the case was one of impacted gall-stone in the ileum, and that there was little or no hope of relief except by operation. I was led to this diagnosis by the following points. The invasion was sufficiently sudden to bring it within the class of acute obstructions, and there was a total absence of distension of the abdomen. I therefore excluded all diseases of the great intestine, including volvulus. At the same time, the onset was not sufficiently sudden for an internal strangulation or twist of the small intestine. Moreover, there was a total absence of collapse, the vomiting had never been severe, it was not stercoraceous until the fourteenth day, and the pain was far from acute. The absence of blood or mucus in the evacuations brought away by the enemata, the completeness of the obstruction, and the fact that no tumour could be felt, even under chloroform, seemed to negative the idea of acute intussusception. It was quite certain that there was no peritonitis, either chronic or acute. All these conditions being excluded, obstruction from a foreign body impacted in the small

[1] Read before the East Sussex Medico-Chirurgical Society.

Digitized by Google

intestine, either at its narrowest part near the lower end of the ileum, or in some part narrowed by disease, seemed the only probable diagnosis. That the foreign body was a gall-stone I concluded from the history of hepatic colic ten weeks before, accompanied by little, if any, jaundice, and followed by uneasiness in the region below the liver, continuing up to the time of the attack.

On Sept. 29th, at one P.M., Mr. Marcus Beck saw the case with me, and, agreeing in the diagnosis, proceeded to open the abdomen, assisted by Dr. Gamgee, Mr. Brodribb, and myself. Mr. Beck has furnished me with the following account of the operation. The patient, having been placed on a table, was covered with a mackintosh sheet having an oval opening in the middle (an ovariotomy apron). The skin was then carefully cleaned with a 1 in 20 solution of carbolic acid. Ether having been administered, a spray of carbolic acid was turned on. An incision was then made (about three inches in length) in the middle line, the middle of the wound being midway between the umbilicus and the pubes. The abdomen being opened, a coil of distended small intestine showed in the wound. The hand was passed at once into the right iliac fossa, with the intention of feeling for the cæcum, in order to ascertain whether it was distended or empty. Before reaching the cæcum, but close to it, a hard mass was felt in a coil of the small intestine. This was at once drawn up into the wound and out of the abdomen. It was then seen that the gut was completely plugged by a barrel-shaped body of great density. The gut was apparently healthy; its surface was shiny and perfectly free from any sign of inflammation. An attempt was made to push the foreign body forwards, the direction in which it should go being easily recognised by the distended condition of the intestine above it, while below the gut was empty; it would not move with any amount of force which it seemed justifiable to use. It was determined, therefore, to cut it out by a longitudinal incision in the intestine. The opening in the abdomen was carefully plugged with sponges which had been rung out of a warm solution of carbolic acid (1 in 40), and the coil of intestine was laid upon a flat sponge; a small hole was then made in the mesentery close to the gut, immediately above the foreign body; through this a piece of indiarubber drainage-tube was passed and drawn sufficiently tight to occlude the gut, and clamped with a pair of forci-pressure forceps. In this way the escape of fæces from above was effectually prevented. A longitudinal incision was then made at the side opposite the attachment of the mesentery. It was about one inch and three-quarters in length, and was of sufficient size to allow of the escape of the foreign body without bruising the tissues of the gut. A small quantity of very dark fæcal matter escaped, which was immediately received on a sponge. The mucous membrane was intensely injected and considerably swollen. But little blood flowed from the incision. The gut having been cleaned, the edges of the wound were brought together by interrupted Lembert's sutures. Fine common sewing needles were used (No. 7), threaded with fine carbolised silk. The needle was inserted about a quarter of an inch from the edge of the incision, penetrating the serous and muscular coats only, and brought out about one-sixth of an inch from the edge; then inserted on the opposite side about one-sixth of an inch from the edge, and brought out a quarter of an inch. About a dozen stitches were required and were inserted. When all the necessary sutures were inserted, they were tied. The closure seemed perfect, the mucous coat being turned in and the serous from each side brought well in contact. The piece of indiarubber tube was now removed; it had made rather a deep impression in the gut, showing the swollen condition of the bowel. The impression began to disappear immediately, the circulation being rapidly restored in the pale part. The incision was then minutely examined to see if anything leaked from it, and nothing was detected. The coil of intestine was then carefully cleaned, the sponges plugging the abdominal wound removed, and the gut replaced in the abdomen. During the whole operation no blood or other foreign matter had escaped into the peritoneal cavity. It was not necessary, therefore, to clean out the peritoneum by sponging or washing. The external wound was then closed in the usual way. The anæsthetic was admirably administered by Mr. [illegible] that [illegible] time [illegible] on [illegible] The [illegible] covered by a layer of sal alembroth wool. The foreign body was found to be a large gall-stone. It was somewhat the shape of a conical bullet, the advancing end being slightly conical, the opposite end flat. It was marked at its base by a smooth, slightly concave facet, evidently formed by contact with another stone in the gall-bladder. The rest of the stone was rough on the surface, and glistening crystals of cholesterine could be seen upon it. This roughness must have considerably impeded its passage down the intestine. It measured 3¼ in. in circumference, 1⅝ in. in length. It weighed almost exactly an ounce. The patient rallied well from the operation. A dose of morphia was administered hypodermically, and at 9 P.M. the pulse was 100, and of good force; there was no pain or sickness, and the patient seemed to be doing well; but on the following morning the pulse had risen to 120, the countenance was anxious, there was slight distension and some tenderness of the abdomen, but no sickness. He died at 3 P.M., exactly twenty-five hours after the operation. No post-mortem examination could be obtained.

In the treatment of this case I was led to go somewhat beyond the orthodox way of feeding in intestinal obstruction by the willingness of the patient to take food, by the fact of its being retained several hours, and from its not, as far as I could see, in the smallest degree promoting vomiting, and perhaps also from having less faith in the value of nutritive enemata than some have. The medical treatment consisted of opium and belladonna—the doses, in consequence of the moderate amount of pain, being comparatively small,—enemata, and, when they no longer acted, aperients. I was led to try aperients from the recollection of a case I had some years ago, when the combined use of aperients and enemata resulted in the passing, after ten days' absolute constipation, of a stone so large that its passage through the anus caused great suffering.

The following points seem worthy of further consideration in this case. 1. What was the cause of death? Unfortunately this question must remain doubtful. He did not die from shock, for he rallied well from the operation. Every precaution was taken to ensure cleanliness, no carbolic lotion except that upon the hands entered the abdominal cavity, the stitches seemed efficiently to close the gut, and well carbolised silk was used, and yet from the period of death it seemed most probable that peritonitis was the cause. The gut, though not actually inflamed at the time of operation, was much congested and swollen. Most probably inflammation developed in the damaged gut after the operation, and in the weak state of the patient proved rapidly fatal. 2. When was the stone impacted? This could not be accurately ascertained. From the size of the gut and the situation in the abdomen it was probably in the lower part of the ileum, not far from its end. That it was the ileum is certain from the absence of the valvulæ conniventes in the part opened. 3. Was the operation necessary, or would it have been safer, having made the diagnosis, to trust to nature? This question is extremely difficult to answer. I find in the Index Catalogue of the library of the Surgeon-General, U.S.A., references to thirty-nine cases of impacted gall-stone. Of these I have been able, with the limited time at my command, to refer to only fourteen. Among them, I find, is a stone measuring 3½ in. passed safely after twelve days' obstruction. In another case there was a stone of a little over three inches, but there is no evidence that it passed down the small intestine; it probably ulcerated from the gall-bladder into the colon. Fagge also mentions one measuring 1$\frac{1}{10}$ in. in diameter, which passed after seven days' obstruction. On the other hand, I found seven stones, proving fatal, which measured less than that from my patient; the smallest had a transverse circumference of only 2½ in., and yet it blocked the lower end of the jejunum, and caused death after fæcal vomiting. It seems, therefore, that although it is possible for a patient to pass stones of this size through the ileo-colic valve, very few succeed in doing so, and probably the percentage of recovery would be greater if operation were resorted to in every case as soon as the diagnosis is made. Unfortunately, however, the diagnosis is very rarely made at all. In almost all the cases I have met with, their nature was only cleared up at the post-mortem examination. I can find no case but this in which the stone has been removed by operation. The disease is far more common in women than in men. In the fourteen cases I have been able to refer to only two were men.

Hastings. [illegible]

CLIMATE AS A THERAPEUTIC AGENT IN PHTHISIS;

WITH AN ACCOUNT OF THE CHIEF SANATORIA FOR PHTHISIS AT HOME AND ABROAD.[1]

BY JAMES ALEXANDER LINDSAY, M.A., M.D.,
PHYSICIAN TO THE CONSUMPTION HOSPITAL, THRONEMOUNT, BELFAST; ASSISTANT-PHYSICIAN TO THE BELFAST ROYAL HOSPITAL, ETC.

I PROPOSE in this paper to consider four questions:—1. Does climate cure phthisis? 2. How does climate cure phthisis? 3. What climates cure phthisis? 4. What cases of phthisis are curable by climate?

1. Does climate cure phthisis? Yes, beyond question. To doubt this fact is to run counter to a vast mass of unassailable evidence and to give way to an unreasoning scepticism. I have met and talked with cured consumptives in many parts of the world—patients in whom the existence of the disease had been diagnosed by competent authorities, and the genuineness of whose recovery was testified by a long life of vigorous activity. These instances of complete recovery are, however, less common than cases of relative recovery, by which I mean those cases in which the morbid process in the lung becomes dormant and the patient lives out his days, but with diminished vitality, and maimed, as it were, for the rest of his life. It is an extremely important question to determine how many of these cases of cured phthisis are contingent upon the patient remaining in the country and climate where the cure was effected—are, in technical language, relative to his environment; and how many are so complete as to permit of a safe return to the unfavourable climatic conditions which prevail at home. Every practitioner who sees much chest disease has had distressing cases of consumptive patients who have gone abroad and apparently been cured, but who, yielding to that piteous home-sickness which sometimes assails the stoutest heart and disregards the plainest admonitions of prudence, have returned home, and returned to die. I fear that in a large proportion of cases the cure of phthisis is contingent and conditional, and I do not think we can often regard without serious concern the return of a cured consumptive to those climatic conditions which originally produced or predisposed to the disease.

2. How does climate cure phthisis? Not usually by a single or specific quality of the air or by any definite combination of meteorological conditions. The old notion of "healing air"—viz., that the air by virtue of some inherent virtue exercised a direct local curative influence upon tubercular deposits—is a delusion. Bournemouth and Arcachon profess to cure phthisis by the balsamic emanations from their pine forests, but if such emanations have any influence (which is quite doubtful), such influence is but a small and unimportant factor in their general climatic effect. The nearest approach to a specific climatic influence upon phthisis is found in the action of the climates of high altitudes, which has been abundantly proved to depend mainly upon the rarefaction of the air. To sum up this branch of the subject, climatic treatment cures phthisis by removing the consumptive from the evil influences of unfavourable meteorological conditions and of an injurious soil, and by transferring him to a climate where fresh air, sunshine, and an out-door life may be freely enjoyed, and where, in consequence, the processes of respiration, digestion, and sanguification proceed with sufficient energy to combat successfully the hereditary tendency or individual proclivity to pulmonary disease.

3. What climates cure phthisis? There are very many sanatoria which have been *alleged* to cure phthisis, but it is a significant circumstance that, while every year introduces some new claimant to attention, it also witnesses the dropping from the ranks of some discredited impostor. Time was when Montpellier was the reigning favourite. It is now almost forgotten. Pau and Nice have quite outlived their once universal fame. Jersey, with its capital St. Heliers, once boasted great things, but we now know that its boasting was vain. The above losses of popularity have been amply justified, but other fluctuations of medical opinion and practice have been more arbitrary. The most favoured health-resorts of the past generation were Madeira and Egypt. They are both at present under a cloud, but it will probably be a temporary cloud, as, for properly selected cases, these noted and long famous sanatoria have very decided advantages. The chief feature of modern practice is the great and growing popularity of the high altitude stations.

The number of health-resorts for phthisis is so vast that some classification must be attempted, though no satisfactory classification has yet been suggested. In default of better, let us divide sanatoria into three classes:—(*a*) The marine resorts. (*b*) The dry inland resorts. (*c*) The mountain resorts.

(*a*) The best marine resort, if I may so express it, is the ocean-going ship; on the high seas the peculiar features of the marine climate are enjoyed in perfection. Those features are great purity of the air and freedom from all sources of contamination, marked humidity, and very great equability, both as regards temperature and hygrometric condition. The general influence of ocean air is decidedly tonic, and improvement in appetite and gain in weight are almost universal on shipboard. The disadvantages of the sea voyage are—liability to sea-sickness, which is a serious difficulty in only 2 or 3 per cent. of cases; the want of proper sleeping-room, and the consequent contamination of the air at night; and the absence of many home comforts. No consumptive should undertake a sea voyage unless he can afford to travel with tolerable comfort, pay for a roomy cabin, and have suitable companionship. The sailing-vessel should in nearly every case be preferred to a steamer, and the voyage to Australia or New Zealand *viâ* the Cape of Good Hope is the most adapted to the consumptive. The usual time of departure for Australia is September or October, but this is an unfortunate arrangement, as the invalid thus lands at the antipodes at the beginning of summer, the worst and most trying of the Australian seasons. A better plan is to set sail in July or August, so as to reach Australia during the charming and healthful time of spring. Sailing-vessels occupy from seventy to ninety days upon the passage. The sea voyage confers at least temporary benefit upon the great majority of consumptives, except those cases of great debility and prostration which should not be sent to sea. In the course of my four long voyages I have had as fellow-passengers a vast number of consumptives, who, with scarcely an exception, were happy and comfortable at sea, gained in weight, and experienced an amelioration of all their worst symptoms. It is a dictum of most writers upon the climatic treatment of phthisis that hæmorrhagic cases should not be sent to sea. I greatly doubt the accuracy of this view. I have only known two cases of hæmoptysis occurring at sea, and neither proved serious. I am quite unable to understand any theoretical ground on which hæmorrhage should be apprehended on shipboard. When the sea voyage fails, the causes of failure are often obvious. Excessive debility, rendering the patient unable to accommodate himself to the novel conditions of life at sea, sea-sickness, longing for home, which is apt to be strong amid the solitude of the ocean wastes, an uncomfortable ship, an overcrowded cabin, and an improper dietary—these often retard or prevent the beneficial influence of the sea voyage. There is one important point, of which my experience has afforded me several melancholy instances—viz., the proneness to relapse on reaching land. The patient should be warned to practise great caution as regards diet, exercise, and general habits on landing after a long voyage. Nearest to the climate of ocean comes that of the ocean islands, such as Madeira, Teneriffe, the Azores, Nassau in the Bahamas, &c. Cases that have been known to do well on shipboard may be sent to these resorts with tolerable confidence, the climatic conditions being similar. There is admirable accommodation at Madeira, and many cases do well there; but diarrhœa is so epidemic as to be known as the "island complaint," and no case of phthisis should be sent there in which intestinal troubles have been much marked. The climate is very soft and soothing, and grateful to those suffering from bronchial or laryngeal complications, but it is deficient in tonic influence, and its effect upon the general course of the disease is decidedly inferior to that of more bracing localities. Patients may be sent there who lack the necessary vitality to enable them to react to tonic climatic conditions. Of the drier and more tonic marine resorts, Algiers, Tangier, and Malaga are perhaps the best. The reputation of the Riviera is decidedly on the wane. Many seasons are delightful, but often the mistral is exceedingly treacherous, and snow-storms

[1] Paper read before the Ulster Medical Society, Feb. 2nd, 1887.

Digitized by Google

are not unknown. The chief stations in the Riviera are Hyères, Cannes, Nice, Monte Carlo, Mentone, Bordighera, and San Remo. Nice has quite lost its old reputation, owing to the sudden changes to which it is subject. Cannes is a lovely spot, but inferior to Mentone and San Remo for the purposes of the invalid. Where much shelter is a desideratum, Mentone should be preferred. Otherwise, San Remo possesses the best climate in the Riviera. Algiers is a great favourite at present. It possesses a dry, sunny, warm winter climate, with complete immunity from frost and fog. There are very few days on which the invalid cannot enjoy several hours of out-door life, and the proportion of charming weather is far higher than upon the northern shore of the Mediterranean. Consumptives should in no case reside in the town, which is very dusty and a prey to evil odours, but should choose the suburbs, such as Mustafa Inférieur or the Village d'Isly, and, as spring advances, a change inland to the dry and bracing climate of Hammam R'Ihra or Milianah may be advantageously adopted. Tangier resembles Algiers in its general climatic features, but the accommodation is inferior, and it is a very dull place. Malaga has a very good climate, but there is nothing to do, and patients soon weary of it. Biarritz is an excellent place in autumn, but too windy for a winter residence. Arcachon suits cases where nervous irritation is marked. As regards the marine resorts in Britain, Ventnor, Bournemouth, and Torquay are the best, and I have given them in what I consider as the probable order of merit. Ventnor is the warmest and driest of these resorts. Bournemouth has more shelter, and suits cases which cannot tolerate the more decided marine flavour of the air at Ventnor. Glengarriff is probably the best winter climate in Ireland. Rostrevor has some local repute, but it has little to recommend it. There are some excellent marine resorts in California, of which Santa Barbara is the best known. The Californian coast in its southern parts enjoys a remarkably dry, bright, and tonic climate, well adapted for many cases of phthisis. Tasmania has a climate of great salubrity, but there are many very diverse climatic types included within the area of that small island. The west coast is stormy and wet, and wholly unsuitable to the invalid. The southern coast is somewhat too windy. The best regions for the consumptive are the north and north-east shores, which possess one of the brightest, mildest, and most genial climates in the world. The coast region of Australia cannot in general be commended, being a sort of battle-ground for the breezes from the sea and the hot blasts from the interior, and the climate is in consequence fickle and stormy. The most favoured region in Australia for the consumptive is the interior plain, of which I shall speak presently. The best marine resorts in New Zealand are Napier and Nelson. Speaking generally, the reputation of marine resorts has somewhat waned in proportion as the fame of the dry inland and the mountain sanatoria has increased. No marine resort is, I think, quite equal to the ocean voyage, where the latter can be enjoyed under the most favourable circumstances.

(*b*) The dry inland resorts. The best of these are Nubia, the interior parts of Algeria, the Orange Free State, and the vast interior plains of Australia, especially the Riverina of New South Wales and the Darling Downs of Queensland. I am inclined to rate very highly this type of climate in the treatment of phthisis. A large proportion of the cases of complete cure which I have known have been effected by a prolonged residence in some dry inland region, the cure being, without doubt, in nearly every case materially promoted by the adoption of an open-air life, plain diet, and simple manners. Of the four regions mentioned, probably the Orange Free State is the best, as it possesses an advantage over the others in being at a considerable elevation. But personal considerations will lead in many cases to the selection of Australia, and it is no small advantage to send the consumptive to the land where he will meet his own kith and kin, where the language, food, and manners of the people will be familiar and congenial to him, and where he may possibly find such remunerative employment as may induce him to settle permanently. Speaking broadly, I would send to Australia only those consumptives to whom a dry inland climate would be thought to be beneficial, advising them in all cases to avoid the coast regions, and especially the capital towns, to go inland at once, settle upon some farm or sheep station, and make up their minds to a residence of at least two years. A large proportion of cases would thus be cured. To recommend Australia as a sanatorium for phthisis without keeping these points in view is to invite failure and disappointment.

(*c*) The mountain resorts. These sanatoria have sprung into sudden favour within the last twenty years, and their popularity grows yearly. The chief are Davos, Wiesen, St. Moritz, and the Maloja in the Alps; Colorado Springs and Manitou in the Rocky Mountains; Bogota, Jauja, and Huancayo in the Andes. The almost complete immunity from phthisis enjoyed by residents at high altitudes first suggested their adoption. The most important feature in the medical climatology of the mountain sanatoria is the rarefaction of the air, which promotes respiratory activity, the expansion of the chest, and the absorption of morbid deposits. The dryness, the purity of the air, and the freedom from organic dust are all of importance, but subsidiary to the atmospheric rarefaction. These sanatoria fall into two classes—the cold and the warm. In the Alps and the Rocky Mountains the winter climate is marked by perpetual snow and severe frost. In the Equatorial Andes the climate at high altitudes is one of perpetual spring—humid, warm, and vernal. The mountain resorts have proved most efficacious in the following cases: delayed recovery from pneumonia with threatening tuberculosis, chronic pleurisy with much fibroid change, incipient catarrh of the apex, chronic tubercular phthisis, with good reaction and the retention of fair constitutional vigour, whether cases of primary disease limited in extent, or single cavity cases without tendency to extend. Hæmorrhagic cases do well, although the profession was long inclined to exclude such cases from the mountain treatment owing to the unfortunate influence which a false analogical reasoning had exercised upon them. The contra-indications against the adoption of this line of treatment are: Weak circulation, which is absolutely prohibitory, senile change, the *eretische constitution*, extreme debility, and marked and progressive emaciation. Moderate pyrexia is not a hindrance, while sweating and fluxive diarrhœa are usually relieved at high altitudes. Where the cold mountain resorts fail the warm may often prove useful.

4. What cases of phthisis are curable by climate? I have hitherto spoken somewhat dogmatically, as the general principles of medical climatology and the general characters of the sanatoria for phthisis admit of very precise statement; but in dealing with this last question—to which I have more than once been obliged to make incidental allusion—I desire to speak with that diffidence which becomes the therapeutist. In many cases there are few more difficult problems than to determine whether a given case of phthisis will respond to climatic treatment, and what type of climate affords the best hope of success. Speaking generally, only chronic cases with fair reaction are suitable for climatic treatment. If the disease has a well-defined onset and threatens to run an acute or semi-acute course; if the patient steadily loses ground and shows no gain in weight or other sign of rally under treatment; if the process in the lung is progressive and there are no evidences of repair—in each and all of these cases the interests of the patient will be best served by vetoing climatic treatment. The patient will die soon and die anywhere, and he may as well be allowed to pass his last days amidst the comforts and sympathies of home. Cases marked by circulatory weakness, with fast, feeble, fluttering pulse, slight cyanosis, and persistent coldness of the extremities, are very unfavourable for climatic treatment, and should on no account be sent to the mountains. Cases in which laryngeal or intestinal ulceration or renal complication have supervened upon the ordinary type of the disease should be allowed to die at home. Cases in which anæmia appears early and is well marked are unlikely to respond to climatic treatment. On the other hand, we see a vast number of cases of phthisis in which the onset is very gradual and the constitutional involvement for a long time slight. Such cases nearly always improve, even in this climate, under a system of high feeding, fresh air life, and cod-liver-oil, and I entertain no doubt that a considerable proportion of them may be completely cured by removal to a suitable climate and the adoption of a prudent mode of life. In determining the climate to be chosen, it used to be taught that the condition of the bronchial mucous membrane was the chief guide: that cases with much bronchial catarrh should go to a dry climate, cases with dry irritable mucous membrane to a moist sedative climate, and so on. I greatly doubt the utility of this rule. Phthisis is not bronchitis, and all

Digitized by Google

analogies for its treatment drawn from our knowledge of bronchitis are not merely unfruitful but misleading. In the therapeutics of consumption we have given up directing our medicinal treatment to the bronchial mucous membrane, and I am unable to see why we should still base our climatic treatment on a theory which we thus implicitly acknowledge to be unsound. Hippo, paregoric, and squills have almost disappeared from our treatment of phthisis; and climatic sanatoria, which soothe the patient's cough at the expense of his appetite and strength, must follow them into deserved oblivion. The consumptive does not die of his cough. He dies of progressive wasting. We have thrown aside expectorants and anodynes in favour of good food, exercise, and such aids to nutrition as cod-liver oil, hypophosphites, maltine, &c., and we must, when possible, choose climatic resorts which are tonic and stimulant rather than those that are mainly sedative. The vital point about any climate is, will it promote nutrition? In early uncomplicated cases with vigorous circulation I think the mountain climates offer the best hope. If the circulation be feeble, or if there be much nervous irritation, the choice will lie between the sea voyage and residence in such dry inland resorts as Upper Egypt or the interior plains of Australia. The sea voyage has the great recommendation that it rarely does harm, except in those very advanced cases which are beyond the reach of all treatment. If the patient objects to the mountains and shrinks from the long sea voyage, I think Algeria or Morocco should be preferred to France or Italy. Let me say, in conclusion, that climatic change is a snare instead of a help, a curse rather than a blessing, if it be regarded as a complete therapeusis in itself, and as enabling the patient to dispense with the usual lines of treatment and his customary precautions. Climate is not a specific. At best it is only a condition of cure, and we may expect it to be effectual only when the patient's food, habits, occupation, and mode of life are wisely regulated so as to facilitate its beneficent influence.

Belfast.

TRACHEOTOMY.

BY WALTER WHITEHEAD, F.R.C.S.E., F.R.S. ED.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY, ETC.

THE operation of tracheotomy is in many cases confessedly a difficult one to perform. This is emphatically shown by the amount of literature written upon the subject, by the many different ways which have been described and practised, and also by the many dangers warned against. My excuse for proposing any change in the methods usually adopted is the simplicity of the plan I have to suggest, and the ease and success which have invariably attended its performance.

The operation is performed as follows. The head of the patient being bent well back over a pillow, an incision is made in the usual situation, but of rather greater length than is common. The incision extends through the skin and fascia, as deep as the interval between the sterno-hyoid muscles. The scalpel is now laid aside, and the raspatory used, not only to separate the sterno-hyoids, but to split the strong fascia which runs down from the hyoid bone to enclose the isthmus of the thyroid gland. This fascia is split to a distance extending from the upper limit of the incision down to the isthmus below—that is, supposing it is desired to open the trachea above the isthmus. The split fascia is then pushed to right and left with the raspatory. Should there be any difficulty in doing this, the fascia is separated to some extent on each side from the upper border of the isthmus. Proceeding carefully, the isthmus itself can be pushed down and the trachea exposed to the necessary extent. If the trachea is to be opened below the isthmus we proceed in a similar manner, remembering that here, however, we have between the fascia and the trachea a quantity of areolar tissue in which lies the inferior thyroid plexus of veins. The front of the trachea can in this way be cleared perfectly, and, since the method is bloodless, the rings of the tube are seen glistening white at the bottom of the wound. The trachea can now be fixed readily between the left index finger and thumb, and opened to the desired extent. There is little or no difficulty in introducing the cannula, since the trachea can be so steadily fixed and the incision into it so clearly seen.

The above method resembles in many particulars the "bloodless" method of Bose, but in the latter operation the scalpel is used to a much greater extent than in the operation here advocated, and when the scalpel is not to be used the use of the director is advised. But the walls of the veins in this region are very thin, and the sharp edges and point of the director have been frequently known to tear these vessels and rob the operation of its bloodless character. This tearing of the veins is much less likely to occur if the raspatory is used. Moreover, the above operation with the raspatory is not only suitable for cases where the surgeon has abundant time at his disposal, but is advised even in emergency tracheotomy; since, although perhaps a little more time is required to reach the trachea, the certainty that when once reached it can be quickly opened and entered is a distinct ultimate gain. What is urged in favour of the operation is—firstly, the ease with which it can be performed; secondly, the small number of instruments required; and, thirdly, the manner in which it meets the four difficulties usually enumerated—viz., of reaching the trachea, of hæmorrhage, of opening the trachea, and of introducing the cannula. Again, it avoids, in an especial manner, those dangers met with when the operation is performed, as it too often is, practically in the dark, from the bleeding, and the not sufficient separation of the parts; thus it is impossible, in this operation, that the cannula should be pushed down between the trachea and the fascia lying in front of it, or that it should be thrust, as has actually happened, into the internal jugular vein. Our resident surgical officer, Mr. J. Collier, who is frequently called upon to perform tracheotomy in emergencies, has definitely adopted the operation described since seeing me open the trachea some months since for the extraction of a gun cap accidentally inspired into the trachea.

Manchester.

THREE CASES OF STONE IN BOYS; REMOVAL BY SUPRA-PUBIC CYSTOTOMY.

BY THOMAS WALKER,
SURGEON TO CLAYTON HOSPITAL, WAKEFIELD.

CASE 1.—Arthur M——, aged three years, was operated on by me on August 2nd. Dr. Wright administered chloroform. I was assisted by Mr. Eskrigge, house-surgeon, and Mr. J. W. Walker, Dr. Holdsworth also being present. The bowel having been emptied by an enema, and chloroform given, an indiarubber rectal bag was introduced, and three ounces of warm water injected into it. A catheter was then passed, and the bladder gently distended with a warm solution of boracic acid, the catheter removed, and a tape tied round the penis. An incision, about two inches and a half long, was made through the skin above the pubes and the tissues separated with the finger-nail and knife down to the bladder; two hooks were introduced into the bladder, when a little fluid escaped. A small opening was made between the hooks, which was enlarged by the finger, and the stone, which was easily felt, removed. The bladder was then explored and washed out with warm boracic acid solution. The wound in the bladder was closed with fine catgut sutures. Four stout silk sutures were inserted in the external wound, the lower one being left untied in case all the urine did not flow by the natural passage, as no catheter was left in. However, as he passed urine three times during the first night, the remaining suture was tied next day. During the operation no artery or large vein was met with. There was very great tenesmus to expel the rectal bag during the latter part of the operation, which brought down the peritoneum into view in the upper part of the wound. On the fifth day a sudden rise of temperature occurred, with symptoms of extravasation extending into the scrotum, which, I think, was owing to the vesical wound not being entirely healed when the catgut sutures became absorbed, consequently the urine escaped into the tissues. On removing the external sutures, however, the urine passed through a small hole at the lower part of the wound, and the symptoms of extravasation quickly subsided. Two incisions were also made into the scrotum, to relieve the swelling. The calculus was of uric acid, weighing eighty-nine grains.

The following notes of the case were kindly supplied by the

Digitized by Google

house-surgeon:—Aug. 2nd: After the operation the patient was troubled with persistent vomiting. He passed his urine three times during the night, which had no blood mixed with it. Temperature 99°.—3rd: Wound dressed, the dressings were a good deal stained with blood; the lower stitch through the external wound (which had been left untied after the operation) was now tied. The patient passed urine six times during the day, but no blood. The vomiting has now ceased. Morning and evening temperature normal. 4th: No stain through dressings; passed urine naturally; no pain. Temperature, morning, 99°; evening, 99·5°.—5th: Wound dressed; no blood or urine on dressing. Passed urine naturally. Temperature normal.—6th: Passed urine freely; had a very comfortable day. Morning temperature normal, evening 100°.—7th: Wound dressed; looked rather puffy and red about the stitches, so the alternate ones were removed. Urine passed naturally. Temperature, morning, 99°; evening, 101°.—8th: Considerable extravasation of urine into the tissues and the scrotum took place in the night. The dressings were removed and the other two stitches taken out; some urine oozing from the lower end of the wound. The scrotum was incised on each side of the raphe, and fomentations were applied. Temperature, morning, 100°; evening, 100·5°.—9th: Swelling of the scrotum subsiding; urine passed freely from lower part of wound. Temperature, morning, 99°; evening, 99°.—11th: Urine passed freely through wound; scrotum natural size; general health good. Temperature, morning, 98°; evening, 99°.—16th: Part of urine still passing through the wound, which is swollen. Temperature normal.—20th: Only a drop or two of urine passing through the wound.—24th: Wound healed; general health excellent.

CASE 2.—James H——, aged eight years, was admitted suffering from stone. Supra-pubic cystotomy was performed on November 9th; a very rough stone, weighing 50 grains, was extracted. In this case the wound in the bladder was not sutured, and only two sutures were used in the upper part of the external wound. No catheter was left in the bladder, the urine passing through the artificial opening. Twenty-four hours after the operation he had a rigor. Temperature 102°; the abdomen becoming tympanitic, with pain on pressure. Fomentations were applied, and small doses of opium given. On the following day the temperature was 99·5°; pain much less; abdomen tympanitic. On the fourth day, the bowels having acted, the tympanites and pain gradually subsided. The urine was entirely voided through the wound for the first fortnight, then partially by the urethra. The wound gradually healed by granulations, and the patient was discharged well on December 18th.

CASE 3.—Edward N——, aged four years, was admitted suffering from stone. Supra-pubic cystotomy was performed on Nov. 21st; the stone weighed twenty grains. In this case the wound in the bladder was carefully closed with fine catgut ligatures, not drawn tightly, the linea alba was sutured with stout catgut, and lastly the skin, the lower part of the wound in the skin being left open, in case any urine should escape from the bladder; however, not a drop came away, but all passed easily through the urethra to the end. The wound healed quickly, and without any complication.

Remarks.—I think the supra-pubic operation has a bright future before it. I am of opinion that the danger to life will not be found greater than in the ordinary operation, and, as there is no fear of injuring important parts and functions, this must necessarily be taken into account as a factor in its favour.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this Society was held on Wednesday, April 13th, Mr. Tegart, V.P., in the chair. Three new members were elected, and the death of one announced. Applications for grants were read from sixty-three widows, six orphans, and three orphans on the Copeland Fund, and a sum of £1364 was voted, to be distributed among them at the next court. The expenses of the quarter were £56 6*s.* 6*d.* Dr. Birkett, Dr. de Havilland Hall, Mr. Langton, Mr. Morris, Dr. J. M. Bright, and Dr. H. M. Duncan were selected to fill the vacancies in the court caused by the retirement of the six senior directors. Mr. Fuller, acting treasurer, was nominated as a trustee of the funded property in place of Sir George Burrows, resigned. The annual general meeting was fixed to be held on Wednesday, May 18th, at 5 P.M.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THREE CASES OF HÆMOPHILIA IN THE SAME FAMILY.

BY HENRY SKELTON, M.D., M.R.C.P.

IN 1881 I was called to A. P——, a lad of about twelve years of age, who was passing blood in his urine to a large extent. His case, apparently, was relieved by gallic acid and rest, and I thought no more of it, particularly as I could make out no cause for the hæmorrhage; and as he seemed to get well, I did not trouble any further about him. In 1882 I again saw the lad, who was then bleeding from his nose. The epistaxis yielded to iron internally, and frequent injections of a strong solution of perchloride of iron into the nares.

Soon after this I was called to another child of the same family (aged one year and four months) who had an abscess on the vertex, the result of a fall from a perambulator three weeks before; and as the abscess was causing a great deal of constitutional disturbance I opened it and evacuated the matter. Copious bleeding ensued, and neither pressure nor the usual remedies stopped it, and the child died on the following day from loss of blood.

I have attended A. P—— several times since with bleeding from the mouth and swollen joints, which was undoubtedly effusion of blood. In 1884 I advised his parents to send him into the Bristol Royal Infirmary, where he was placed under the care of Mr. Greig Smith, who has reported his case fully in the *Bristol Medico-Chirurgical Journal*, No. 6, 1884. There is one error in the statement that blood has not been seen in his urine; I myself have seen it, and also nearly all the large joints distended with blood.

On March 23rd of the present year I was called to see Ernest C. P——, aged one year and five months, who, his his mother said, had been bleeding from the mouth since the middle of the night. I found his lips covered and the front of his clothes stained with blood. On examining his mouth the blood could be seen "welling out"—I know no other word that describes it—from the mucous membrane surrounding the teeth. He had cut the four upper incisors, two upper molars, two lower incisors, and was cutting some more teeth; but it was principally from the sockets of the upper incisors that the bleeding came. Various styptics were used, and internally ergot, hamamelis, turpentine, iron, and ruspini were all tried, and apparently without much effect, as the child died. He had become very anæmic, and before death took place was said to have been convulsed.

Remarks.—Heredity is the supposed cause in all these cases. The mother I have attended in several labours, and she always loses a great deal of blood, but generally does well, and is up, as a rule, on about the ninth or tenth day. She frequently suffers a great deal from attacks of asthma, hypodermic injections of morphine and grindelia robusta speedily giving relief. May not this neurosis, of which so little is known, have something to do in predisposing these boys to be bleeders? She—the mother—is one of eleven, three only of whom grew up, two boys and herself. One of her brothers is still alive; the other died from gastric ulceration. Her father, she states, died from asthma at an early age. That is all the family history I can get, and it is, I am sorry to say, a very meagre one.

Downend, near Bristol.

DISLOCATION OF THE SHOULDER; REDUCTION AFTER EIGHT DAYS BY MANIPULATION.

BY E. L. HUSSEY, F.R.C.S. ENG.

As a case of double right-angled traction, the following may be worth publishing.

A thin, spare man, below middle height, seventy years of age, employed as helper in some stables, fell on the tip of his shoulder at night on July 10th, 1867. He continued at his work, cleaning horses and carriages, and sometimes driving; but he could not raise his elbow, nor could he put

Digitized by Google

his hand behind him. He was sent to me on July 18th, by a practitioner to whom he applied for relief. The signs of dislocation at the shoulder were well marked, the head of the humerus resting below the coracoid process. After taking off the man's shirt, I laid him on his back upon a table, close to the edge, and attempted to make extension with my foot in the axilla as I sat on a chair at his side. Finding the position inconvenient, I gave up the attempt. Then, standing at the end of the table, behind the man's shoulder as he lay on his back, I drew the arm away from his side, with the forearm flexed at a right angle and the wrist raised perpendicularly upwards, the hand rather inclining to fall downwards. I kept the limb in that position by hooking my finger in the bend of his elbow, and diverted the man's attention by talking upon indifferent subjects. Forcible extension was not wanted. The muscles soon relaxed, and I then let the hand fall over, thus rotating the head of the humerus inwards, and the bone slipped at once into the glenoid cavity. The man ultimately recovered the perfect use of the limb.

Oxford.

BILHARZIA HÆMATOBIA.

By W. K. HATCH, M.B., M.R.C.S.,
SECOND SURGEON, JAMSETJEE JEJEEBHOY HOSPITAL, BOMBAY.

AFTER observing closely twelve cases of bilharzia hæmatobia in Bombay, where the disease appears to be more common than formerly, especially amongst Mussulmans who have made a pilgrimage to Mecca, I venture to send the following point in diagnosis, which may be of use to army surgeons, now that invalids are constantly returning from Egypt.

1. Pain during micturition, with stoppages of short duration. The pain is said to be of a *pricking* character, generally felt at the root of the penis, or sometimes in the glans. It is caused, I suppose, by the passage of the sharp-pointed ova, while the stoppage may be due to spasm set up by them or to clots. The character of this pain becomes important when no clots can be found in the urine.

2. The passage of a few clots of blood at the *end of micturition*. The urine is seldom seen discoloured, but a few small clots and shreddy fragments of fibrin will be seen, especially on standing. If the latter are examined, ova in quantity will usually at once be found; not so often in the blood clots. Should there, however, be no such fragments, a catheter may be passed, and the eye examined on withdrawal; shreds and ova will usually be brought away. It saves much trouble to do this, as the urine may be searched in vain; and the symptoms, even though ova are not found at first, will give rise to strong suspicion. In hæmaturia due to filaria sanguinis the urine is much discoloured, and jelly-like yellow clots are often present in large quantities, while there is no pain and rarely stoppages during micturition. I may add that the patient with bilharzia is often a strong robust man, and not the least anæmic, unless the disease has lasted for years. The time between the contraction of the disease and the passage of blood and other symptoms may be very short; one patient, who stayed at an hotel at Suez for fourteen days, suffering from them a month after his return to Bombay.

Bombay.

CASE OF POISONING BY HYDROCHLORIC ACID.

By C. H. ROBINSON, F.R.C.S.I.,
MEMBER OF THE COURT OF EXAMINERS, R.C.S.I.; FELLOW OF THE ACADEMY OF MEDICINE.

THE following short notes of a case of attempted suicide may be of interest, inasmuch as hydrochloric acid is not often used for this purpose.

On June 16th last a gentleman aged fifty, who for some time previously had lost his employment in a firm where he had been engaged for many years, during a fit of drinking swallowed an ounce of hydrochloric acid which he had obtained from a neighbouring chemist. Within a few minutes afterwards his wife gave him a mustard emetic, which acted several times, and I was sent for and saw him within an hour of the attempt on his life. He was much depressed, in a cold sweat, and complained greatly of pain in the stomach. There were a couple of stains from the acid about his lips. Very fortunately for the patient, he had taken his dinner shortly before he swallowed the poison. I prescribed the usual remedies, such as milk, magnesia, eggs, &c. The following day he complained of pain in the throat as well as in the stomach, and spat up constantly a quantity of thick mucus. Small doses of laudanum were given at short intervals to lessen the irritation of the stomach, but he was able to take without difficulty beef-tea and egg flip. After a few days the pain in the throat and stomach disappeared, and since then he has never complained of any difficulty in swallowing. I was told he had swallowed a quantity equal to two tablespoonfuls of the acid, but as the throat was affected in only a trifling degree I fancy the amount taken must have been considerably less.

Dublin.

AMPUTATION OF PENIS; COCAINE AS A LOCAL ANÆSTHETIC.

By DUGALD CHRISTIE, L.R.C.S., L.R.C.P. ED.

THE following case may be interesting as illustrating the value of cocaine as a local anæsthetic in minor surgery.

The patient, a Chinese merchant in this city, suffered from epithelioma of the penis. For over two years he had been going the round of the native practitioners, consulting them in vain, and only suffering severe torture from their often heroic but barbarous treatment. He came to me in a state of despair—weak, emaciated, with his nervous system, from prolonged pain and sleeplessness, in a state of extreme irritability. Although a year previously he had refused to submit to amputation as I recommended, he now readily agreed to our proposed method of treatment. Chloroform was carefully administered, but after a few inhalations, proving a bad subject for a general anæsthetic, it was decided to try cocaine. Twenty minims of a 5 per cent. solution of the hydrochlorate were injected, in five-minim doses, at short intervals, round the seat of incision, and into the urethra. A quarter of an hour after the first injection the part was amputated without the patient experiencing the slightest pain; indeed, he would not believe me when informed that the operation was over. Another point of interest is that, except from the large bloodvessels, there was hardly any hæmorrhage, doubtless due to the constricting effect of the drug on the capillaries. As to the after-treatment, there is nothing worthy of note, only that the anæsthesia produced seemed to last over a day, and that the patient complained of no pain after the operation. He recovered without a bad symptom, and now enjoys excellent health. I constantly use cocaine in eye operations, cataract, iridectomy, pterygium, and also in cases of fistula in ano, abscesses, &c., with most satisfactory results.

Houkden, North China.

CASE OF PLACENTA PRÆVIA.

By M. H. TAYLOR, L.R.C.P., L.R.C.S. EDIN.,

ON March 9th, at 6.30 A.M., I was called to a woman who was being attended by a midwife. The patient is a very stout woman, forty-three years of age, and was seven months advanced in her fourteenth pregnancy. I found her almost in a state of collapse, her lips bloodless, and I could scarcely feel her pulse at the wrist. I heard she had been bleeding since 4 A.M. On examination, I found, as I suspected, it was a case of placenta prævia. When I saw her the hæmorrhage had stopped, but on the least movement it came on again. Not thinking it judicious to do anything till she had rallied from the state in which she then was, I gave her brandy and milk, and waited for about half an hour, when she felt better. I then examined her more fully. The os was very soft and dilated, sufficiently to admit two fingers. I found the placenta immediately inside the os; it was detached and felt slightly ragged on the right side, the head presenting. I swept my fingers round and detached as much placenta as was within reach, and as I did this the os dilated so that I was able to pass my hand into the uterus, when by the bipolar method I turned the child and brought down the first leg I could seize (the right), till the foot protruded from the vagina. This I found stopped the hæmorrhage effectually, so I did nothing more for two hours, except to put on a binder, when the

Digitized by Google

patient felt much stronger and the wrist pulse was easily felt. I then brought down the other leg and delivered her. The child was dead. The placenta came away with a little trouble. I washed out the uterus with permanganate of potash solution, and at 11.30 A.M., when I left her, she felt quite comfortable. I repeated the washing out every day for a fortnight, during which time several small portions of membrane with many clots came away. Her temperature never rose above normal, and she made an uninterrupted recovery. I saw her on April 12th, and she felt quite well, and I hope will be able to resume her occupation of a laundress in a short time.

On subsequent inquiry, which I had not time to make at first, I was told that the hæmorrhage first came on at the latter end of January, was like ordinary menses, and lasted one day, when with rest it stopped. A week afterwards there was another "show," lasting the same period; four days after this a third came on, which ceased in a few hours; two days later she passed a large clot. On March 6th there was a little more hæmorrhage, which lasted an hour. The next was on March 9th, when I saw her. I have since learnt that the patient has a somewhat curious record of confinements. She has had fourteen children, and three miscarriages at three months each. She has ten children living, their ages varying from twenty-two to three years, and all healthy-looking. Her tenth was a case of spina bifida, and lived nine days. Her thirteenth was also spina bifida, and lived fifteen days. The first spina bifida was, I understand, tapped twice, but the second was not interfered with.

Richmond, Surrey.

LIGATURE OF THE INNOMINATE.

By THOMAS HENDERSON, M.B., C.M.

I HAVE thought the following brief notice of a somewhat rare operation of sufficient interest to merit insertion in THE LANCET.

The patient, a man of about forty-five years, was suffering intense pain from pressure by a very perceptible aneurysm of the second part of the right subclavian. Other means having been tried with no good result, Professor Durante of Rome determined upon ligature of the innominate. Accordingly, on March 25th the operation was performed, with strict antiseptic precautions, the vessel being tied in two places—viz., immediately below the junction of the subclavian and common carotid, and again slightly lower down. The vertebral artery was also tied. The ligature used was No. 3 carbolised catgut. The after-progress, up to the present date (April 5th) has been most satisfactory. Circulation in the right upper limb and side of the head has been completely restored, and the patient's general health is good, with the exception of obstinate constipation, which may account for a rise of temperature having occurred. The external wound, excepting a small drainage aperture, has healed by first intention.

ST. THOMAS'S HOSPITAL.

SUCCESSFUL REMOVAL OF RIGHT OVARY FOR CYSTIC DISEASE NINE MONTHS AFTER OPERATION FOR HYDROSALPINX.

(Under the care of Dr. GERVIS and Mr. SYDNEY JONES.)

IN August of last year (see THE LANCET, vol. ii., p. 399) we published an account of the operation which this patient underwent for the removal of hydrosalpinx on the left side. She had suffered from pain and symptoms referred to this disease for four years; these had followed the birth of a child, and were so severe as to almost completely incapacitate her for any employment. At the operation the right ovary was apparently healthy, and was therefore not removed. She continued well for some weeks, and then pain commenced in the right side, making further operation necessary. We are indebted for the notes of the case to Messrs. Blunt and Sansom.

A. L——, aged nineteen, was readmitted under the care of Mr. Sydney Jones on Jan. 12th, 1886, after having been some months at a convalescent home, to which she went on her discharge from the hospital in June, 1886, having undergone an operation for hydrosalpinx on the left side. She now complained of great pain in the right side of the abdomen, which was persistent, but varied in intensity, increasing in paroxysms at intervals two or three times a day. It was also increased by any muscular efforts, and during the catamenial periods. Since the previous operation the catamenia had been regular, but scanty and very painful. She also complained of dragging pains in the lower part of the back after ordinary exertion. Pain had existed since the operation of last year, but had been gradually increasing in severity. The abdomen was somewhat distended, having a well-marked cicatrix in the middle line, without evidence of protrusion. There was considerable tenderness on pressure in the right iliac fossa, and also in the umbilical region. No tumour could be felt. The general condition of the patient appeared healthy, and the urine was normal. but she did not sleep well on account of the pain. On Jan. 30th, there was much pain in the right side, right hip, and back. The catamenia ceased the day before; had been very painful and scanty, lasting four days. She was transferred to the care of Dr. Gervis, under whose treatment she continued until the end of February.

On Feb. 15th the following note was made: "The external parts look healthy; there is, however, slight granular erosion of the external os. On passing the sound the uterine axis was found to be slightly retroverted, but of normal length. No pain on touching the fundus, and no hæmorrhage followed the withdrawal of the sound. On digital examination of the left fornix, no pain was felt by the patient, but when the finger reached the right fornix there was considerable pain, and a semi-elastic ovoid swelling was felt."

No improvement having followed the treatment employed up to this time, Mr. Sydney Jones again took her under his care, and on March 1st performed the following operation, the nature of which was explained to her. Ether having been given, an incision about three inches in length was made in the old cicatrix in the middle line of the abdomen. The peritoneum was opened with care after the arrest of all hæmorrhage, a finger introduced, and the peritoneum incised for the whole length of the wound. A large flat sponge was then introduced to keep the intestines warm, catch any blood, and keep the bowels out of the way. The ovary was then brought to the surface, and removed after the application of a double silk ligature to its pedicle, this being returned to the pelvis. The ovary was double the normal size, and several cysts were found throughout its body. The Fallopian tube was normal. On the left side the parts were healthy. There was no adhesion of the abdominal contents to the old cicatrix. The wound was closed with alternate silk and catgut sutures. The operation was done under the carbolic spray, and the wound dressed with iodoform, iodoform gauze, and salicylic wool. Morphia was given hypodermically in the evening, and she had a fairly good night.

March 2nd.—She complains of great thirst and a good deal of pain in the abdomen. Temperature at 2 A.M. 100°; at 8 A.M. 99°. Pulse 105.

On March 5th the wound was re-dressed and two sutures removed. On the 8th all the sutures were removed and from along the track which they had made pus exuded on pressure. For some time after the operation it was necessary to give her morphia injections, for although she did not appear to suffer much pain, still she was restless and very impatient of control, being difficult to manage, as on the former occasion. The suppuration which was noted on the 8th extended to the wound, and it was necessary to open this up somewhat in order to give freer vent. Much care was taken with the diet; during the first twenty-four hours only ice was allowed, then a drachm of milk every hour for a day, then this quantity was increased, and so on until it was considered safe to allow solid food. When suppuration came on in the wound and the temperature rose (on one occasion, the 8th, it reached 103·4°) the previous dressing was changed to boracic acid and warm water, strapping being applied after the removal of the sutures. When she

Digitized by Google

left the hospital on April 7th there was still a superficial granulating surface of slight extent, but her health was good and she was able to take a long railway journey. The abdomen was supported by a belt, and since she has been to the convalescent home, to which she went on leaving, her general strength has improved; she has lost her pain.

EXTRAVASATION OF BLOOD INTO THE THIGH; GENERAL TUBERCULOSIS; NECROPSY.

(Under the care of Mr. CROFT.)

The patient whose case is recorded below was admitted into St. Thomas's Hospital on the 27th of March, 1884, suffering from multiple fractures of the bones of the face, and fracture of the base of the skull and of the radius on each side. Optic neuritis developed under observation, and also left internal strabismus (see THE LANCET, vol. i. 1886, p. 105). The following account of the further progress and ending of this case, and especially of the post-mortem, is unusually interesting. The man never appears to have completely recovered from the injuries thus received, and was almost constantly under medical care for various ailments, dying at last from tuberculosis. The position and extent of the fracture of the base of the skull, the evidences of the old meningitis, which had evidently been severe, and the more recent inflammation with tubercle, are the points to which most attention will be directed. It is not often that we are able to follow throughout its course a case possessing so much clinical interest. The notes of the case have been supplied by Mr. G. R. Anderson.

W. H——, aged forty-one, housekeeper, was admitted into Edward ward on Jan. 21st, 1887, and died fourteen days later. The family history was good. He contracted syphilis fourteen years ago. Until the last three years he enjoyed good health; he then had an accident, sustaining severe injuries, and lost the sight of the left eye. Since then he has had bad health. In April, 1886, he was admitted for ascites and pleurisy, and has attended the out-patient department since for chronic bronchitis. About five or six weeks ago he first noticed pain on the inner side of the left thigh, and thought that he had strained it. The day before admission he noticed swelling in that situation. This seemed to come suddenly; the pain at the time was intense, and he nearly fainted with it.

On admission he was sallow, and had some facial deformity, with internal strabismus of the left eye, there being complete paralysis of the external rectus and complete atrophy of the disc, the result of the old accident. He complained of pain and swelling along the inner side of the left thigh. Here there was a tense ill-defined swelling, extending half-way down the thigh from the flexure of the groin. There is ecchymosis over the upper part of the swelling, and this is said to be increasing; the swelling is tender on deep pressure. The femoral artery can be easily felt, and also the vessels in the leg. His arteries generally are diseased, very hard, and tortuous. The heart is normal. He is under treatment for chronic bronchitis. Urine normal. Temperature 101·8°; pulse 100, full, and bounding. On both legs there are scars of old syphilitic ulcers. A flannel bandage was applied from the foot upwards, and an ice-bag placed over the swelling.

Jan. 24th.—There is some decrease in the size of the swelling; it is less tense, but there is surrounding œdema, and the ecchymosis has spread. There is slight enlargement of the glands in the groin. The limb is quite warm. He is complaining much of headache.

25th.—Warm lead lotion applied to thigh, the condition of which is much the same. There is a somewhat petechial erythematous eruption about the face. Respiration rapid; pulse 96. Tongue dry, and covered with a whitish-brown fur.

28th.—There has been continued complaint of headache, not relieved by iodide of potassium, and only slightly by bromide of potassium. He has been sick constantly during the day.

30th.—Continued headache, with some tenderness of scalp. The rash on the face has faded and the swelling of the thigh is diminished. Tongue and lips dry and brown.

31st.—Some difficulty in breathing, the inspiration being noisy, with expectoration of bronchitic character.

Feb. 3rd.—Patient lies on his back, breathing somewhat heavily; is apathetic, and does not answer questions readily. His lips are dry, brown, and cracked. Tongue dry, with a dark-brown fur. Pulse full, 90. There is some impairment of power in the right arm.

During the last few days he had complete loss of appetite refusing to take food, and emaciated rapidly. The headache was severe, and not much diminished by medicine. He died on the 4th, in an unconscious condition. The highest temperature recorded was on the evening of the 23rd, when it reached 102·4°. It was usually higher in the evening until the 28th, after which date it did not exceed 99°, and was normal before death.

At the post-mortem examination, held on the following day by Dr. Hadden, there was well-marked tubercular peritonitis with adhesions; tubercles in the kidney and also in the lungs. "There was a united fracture, evidently quite old, of the middle fossa of the skull, which extended from near the apex of the petrous bone obliquely forwards and outwards to the anterior margin of the fossa. The margins of the longitudinal fissure of the brain were pretty firmly adherent in the anterior half, and the tips of the frontal lobes were adherent to the dura mater. There were evident signs of old meningitis at the base. The pia-arachnoid was thickened and opaque, especially over the optic nerves, chiasma and tracts, the crura and pons. The optic nerves were dull-grey and the chiasma and tracts distinctly changed in colour. There was no marked diminution in size. The left third nerve was greyer than the right and more flattened. The corpora quadrigemina were normal in size and appearance. The edges of the fissure of Sylvius were firmly adherent, and in separating them several grey tubercles were seen. There was no recent lymph anywhere. The lateral ventricles were a good deal distended with turbid fluid, and their walls extremely softened." A few calcareous plates were found in the spinal arachnoid, chiefly over the lower half posteriorly. A moderate amount of blood was effused into the subcutaneous tissue of the upper and inner part of the thigh. There was no sign of ruptured vessel. The femoral and other arteries were very atheromatous.

MANCHESTER ROYAL INFIRMARY.

RUPTURE OF THE SPONGY URETHRA; SUTURE; RECOVERY.

(Under the care of Mr. WRIGHT.)

THE notes of the following case were taken by Mr. Brazil, house-surgeon.

Peter A——, aged fifty-four, an unhealthy man, formerly a drinker, was admitted on Jan. 29th, 1887. Shortly before admission, while tipping a coal waggon, he was struck in the scrotum by the shaft prop. Soon after the accident he tried to pass urine, but found he was unable to do so, and that the scrotum swelled up.

On admission, the house-surgeon, Mr. Brazil, tried to pass a catheter, but, finding this impossible, Mr. Wright was sent for. On examination, there was a lacerated wound in the scrotum on the left side of the middle line. On passing a catheter along the penile urethra, it entered a large cavity, but could not be got into the bladder. The patient was anæsthetised, and it was then found that the catheter could be passed out through the scrotal wound; the scrotum and perineum were then laid freely open, and it was seen that the spongy urethra was torn completely across a little in front of the bulb, and the ends of the urethra were separated for a distance of from an inch to an inch and a half; the posterior extremity was recognised after a little searching, and a broad director was passed along it into the bladder. There was free oozing from the torn corpus spongiosum. Four catgut sutures were then passed through the divided ends of the urethra, and a No. 10 silver catheter passed from the penis into the bladder along the director, and the latter removed. It was then found that the two ends of the urethra readily stretched, and could be brought together without great tension. The sutures were tightened, and the parts came into good apposition, so that the catheter was not long exposed. The wound was left entirely open and the catheter tied in the bladder.

For the first two days the urine came partly through the catheter and partly through the wound, which was washed out with boracic lotion and dusted with iodoform. On Feb. 3rd the man's condition was very poor; he was feeble, apathetic, and constantly drowsy, and it was feared that his kidneys were too unsound to allow of repair of the injury. The catheter was removed for the first time on the 7th and replaced. For the next three weeks the wound slowly healed, and the man's condition caused much anxiety;

Digitized by Google

diaphoretics and a hot vapour bath, however, improved matters, and he gradually recovered. After the 15th the urine came entirely through the urethra, and the catheter, a No. 10 silver one, was readily passed, every day at first, and later every two or three days. No other bad symptoms appeared, and he was sent to the Convalescent Hospital. On March 2nd he was able to pass urine "as well as ever." The scrotal wound was nearly healed, and though he was weak his general condition was fairly good. About ten days later he left the Convalescent Hospital, a No. 12 catheter having been passed readily before he went home. On March 30th a 12-15 Lister passed easily.

Remarks by Mr. WRIGHT.—Complete rupture of the spongy urethra is of rare occurrence, and, so far as I know, primary suture has not been employed for it hitherto; it, however, seems to be the most rational treatment for such an accident, and in this case has had the best results. Had this not been done, it is probable that the wide separation between the ends of the urethra would have necessarily left the man with a permanent perineal fistula. For rupture of the membranous urethra, suture has already commended itself as a proper line of practice.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Chronic Syphilitic Meningitis, causing Progressive Dementia.—Analysis of 93 Cases of Writers' Cramp and Impaired Writing Power, making, with 75 cases previously reported, a total of 168 cases.

AN ordinary meeting of this Society was held on Tuesday, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Dr. F. WARNER and Dr. FLETCHER BEACH communicated a case of Chronic Meningitis, probably Syphilitic and causing Progressive Dementia. The case was that of a boy aged seven, who came under the observation of Dr. Warner in January, 1879. While an infant he suffered from snuffles, thrush, and sores about the nates. He never had fits. As he grew up he became a strong boy and went to school, where he did his lessons fairly well. He continued bright and well until about eight or nine months before he was first seen. The first thing noticed was a certain difficulty in his movements, the boy at the same time complaining of headaches and crying for slight causes. The symptoms when first seen were then related, and the progress of the case given. He was under observation until September, 1880, when he was admitted into Darenth Asylum, under the care of Dr. Fletcher Beach. There he remained until his death in January, 1882. At the necropsy, twenty-seven hours after death, the dura mater was found adherent to, but easily separable from, a subjacent false membrane, which had evidently been formed for some time. It was attached here and there to the upper surface of the pia mater by thin membrane, and could be traced for a considerable distance along the floor of the skull. The family history showed that the maternal grandmother was epileptic, that the mother was liable to spectral illusions, and that the father had had syphilis. This interesting case, which had been watched carefully for three years, was clearly one of acquired imbecility, due to chronic meningitis, probably syphilitic in its origin, and is representative of many others, where, owing to the influence of heredity, indicated here by the history on the maternal side, the child is born with an unstable brain easily disturbed by any cause. Syphilis is not a common exciting cause of imbecility, but, according to Heubner, hereditary predisposition to nervous diseases appears to exert an influence in determining the syphilitic poison towards the nervous system. Finally, references were made to the connexion between syphilis and idiocy and imbecility. Photographs of the brain and of the membranes were exhibited.—Dr. ANGEL MONEY had made a post-mortem examination on a similar case in a syphilitic infant aged twenty months, in whom there was an extensive sanguiniferous thick false membrane covering the whole of the brain. He likened such cases to peri-splenitis and peri-hepatitis.—Dr. FRANCIS WARNER had observed progressive loss of mental function in two brothers unquestionably due to syphilis. In one case sudden left hemiplegia occurred. There was an arrest of growth in the bones of the affected side; probably syphilitic arteritis was the cause. He thought such cases of mental loss and epilepsy due to syphilis were not uncommon.—Dr. FLETCHER BEACH said that only three cases of undoubted syphilitic imbecility had occurred in 1600 cases at the Darenth Asylum.

Dr. G. V. POORE communicated a paper on an Analysis of 93 Cases of Writers' Cramp and Impaired Writing Power, making, with 75 cases previously reported, a total of 168 cases. This paper is in continuation of one published in the sixty-first volume of the Society's Transactions. The cases reported are given in the form of tables, as an appendix to the paper. They are arranged in three groups,—viz.: 1. Paralytic, 13 cases (10 cerebral). 2. Degenerative, 14 cases. 3. Neuro-muscular, 66 cases. The cases in groups 1 and 2 are nearly all referable to well-understood pathological conditions which affect the brain or spinal cord. The author is of opinion that a not uncommon cause of impaired writing power is to be found in lesions causing slight degrees of paresis of a hemiplegic type, and that the evidence of a slight, long-antecedent, and possibly forgotten hemiplegia may have almost disappeared, except in the execution of an act such as writing, which requires both delicacy and steadiness. Slight degrees of sclerosis affecting the different columns of the spinal cord may, in like manner, be scarcely noticeable except in the effect which they produce on the act of writing. Out of the total 168 cases of impaired writing power, about one fourth are referred to slight central changes in the brain or cord. The remaining 117 cases (66 in the present paper and 51 in the previous paper) cannot, with any sufficient reason, be referred to central change. They form a group which the author calls the *neuro-muscular* group. The objective symptoms of this group (in addition to the impaired writing power) are: 1. Nerve tenderness. 2. Change in the faradaic irritability of some of the muscles. 3. Tremors. These symptoms may occur singly or combined. Nerve tenderness occurred in 50 out of the 93 cases, and in most of these it was the median nerve which was tender. Change in muscular irritability occurred 61 times in the 93 cases. The change was generally a depression, and it occurred chiefly in those muscles which, in the act of writing, are subjected to prolonged contraction, such as the interossei, &c. Tremor occurred in more than half the cases. Many cases were complicated by slight rheumatic conditions of some of the joints. The pathological significance of altered muscular irritability and nerve tenderness is discussed, and it is shown that these conditions occur under such varied circumstances that alone they have little value in determining the nature of the pathological change or its seat. Both, however, may be induced by excessive muscular exertion, and the author continues to regard the depressed electric irritability as symptomatic of muscular fatigue, and is inclined to regard the nerve tenderness as also connected with over-exertion. In the treatment of cases of impaired writing power the first step clearly is diagnosis. For cases of the neuro-muscular group, blistering and other forms of counter-irritation applied to the tender nerve trunks have proved of marked value. Good results have also been obtained from massage and other methods of improving the nutrition of the affected limb.—Dr. C. Y. BISS thought greater prominence might have been given to the mental and physical states of the patient. He had heard of cases of writers' cramp being cured by massage in two or three weeks. The case of a highly nervous man was narrated in which it was shown how important it was to improve the general health of the nervous system. A massage of the whole body once a day and a favourable prognosis confidently expressed to the patient resulted in a cure in six weeks.—Dr. ANGEL MONEY said that in his experience infantile cerebral hemiplegia was very common, and, doubtless, some cases of impaired writing power were due to a long-past hemiplegia. Compensation and substitution allowed of great repair in children. Some cases of impairment in writing were probably due to impaired nutrition of the motor cortex, and others to defect of the spinal centres. This defect of nutrition would tell most on the terminations of the pyramidal fibres and on the endings of the nerves in muscles, for both sets of fibres had their nutrition controlled by the centres, and the nutrition of the fibres might be considered to be more difficult of establishment the further they were away from the source of nourishment and energisation.—Dr. GARROD alluded to impaired power of writing due

Digitized by Google

to the result of pressure on the nerves of the arm during sleep.—Dr. R. J. GODLEE referred to the rheumatic affections sometimes met with in these cases of impaired writing. In some cases of writers' cramp he had noticed a remarkable "clicking" in one or other joint.—Dr. POORE said, in reply, that the mental condition was notably of two kinds. In one the men were of extraordinary energy, and the energy was ahead of the staying power of the muscles and nerves. Great despair was the mental condition of others. Very often in ladies the loss of writing power was largely mental, but this was rare in men. All his work had been with a view to show where the loss of function is situated. Altered irritability and tenderness might be due to central or peripheral lesions, but the evidence was insufficient to say whether the one caused the other, or *vice versâ*. As to the joint conditions, perhaps gout played a share in the causation of some cases. Gouty masses and gouty grating in tendon sheaths Dr. Poore had observed, and also creaking of the shoulder-joint.—The PRESIDENT related cases which were clearly due to fatigue, and easily curable by simple rest and change of occupation.—Dr. POORE said that the writing might be impaired from a multitude of causes—e.g., "rheumatic" affections of nerves, and pressure on musculo-spiral or ulnar nerves. Cases due to fatigue and over-exertion were sometimes of the acute kind. Of these he had seen some, but most of the cases he dealt with in the paper were of the chronic order, lasting for months and years.

CLINICAL SOCIETY OF LONDON.

Three Cases illustrating the Difficulties in establishing Natural Respiration after Tracheotomy, and their treatment by Tracheal Catheterisation.—Large Omental Lipoma successfully treated by Abdominal Section.—Abdominal Exploration for Chronic Intestinal Obstruction; relief of Symptoms by Artificial Anus: subsequent removal of a Growth involving the Splenic Flexure of the Colon; recovery.

AN ordinary meeting of this Society was held on the 22nd inst., Dr. W. H. Broadbent, President, in the chair.

Mr. BILTON POLLARD referred to three cases illustrating the difficulties in establishing Natural Respiration after Tracheotomy, and drew attention to their treatment by Tracheal Catheterism. The difficulty in getting rid of the tube after tracheotomy was by no means uncommon, and in two of the cases related it persisted after most determined and persevering attempts had been made for more than a year and a half by the usual methods. Two of the cases had been for a long time under the care of Mr. Godlee, and had passed into Mr. Pollard's hands when he succeeded Mr. Godlee at the North-Eastern Hospital for Children. The first case was a boy, aged two years and a half, on whom tracheotomy had been performed for laryngitis. For eight months frequent attempts were made to dispense with the tube. Mr. Godlee then catheterised the larynx without benefit. Five months and a half later a piece of india-rubber tubing was passed through the larynx from the mouth to the tracheotomy wound, and left in position for forty-eight hours, without any improvement in laryngeal respiration. The operation was repeated four months later without success. A year and seven months after the tracheotomy Mr. Pollard passed a tracheal catheter from the mouth through the glottis and into the trachea, beyond the tracheotomy opening. It was retained for thirty-one hours, and after its removal the patient continued to breathe through his mouth. The tracheotomy wound was firmly healed in a fortnight, and the child had been perfectly well for the six months that had passed since the operation. In the second case (a boy aged six) the windpipe had been opened for laryngitis. Three months after the operation, all attempts to get rid of the tube having failed, Mr. Pollard passed the tracheal catheter, and in doing so dislodged a piece of granulative tissue, which was coughed up. Pneumonia followed in this case, but the patient was nevertheless cured, and was discharged a fortnight after the operation. He remained perfectly well for the three months that had passed since the operation. In the third case (a boy aged four) the operation had been performed for impaction of a foreign body in the right bronchus. For seven months attempts were made to get rid of the tube. Mr. Godlee then removed granulative tissue from the trachea and catheterised the larynx. The latter procedure was frequently repeated during the next three months and a half. Two years and three months after the tracheotomy Mr. Pollard found the vocal cords adherent; he separated them, and, after dilating the glottis with Lister's sounds, passed the tracheal catheter, which was kept in position for thirty-eight hours. It was not until three weeks after this operation that the patient breathed through his mouth alone. The boy's voice returned, but after four weeks laryngeal respiration was so difficult, owing to the vocal cords having grown together again, that the trachea had to be reopened. The only difference between the plan Mr. Pollard followed and that which Mr. Godlee adopted was that, by keeping the tube in the trachea whilst the tracheotomy wound was allowed to close, the patients were left, on its removal, without the opportunity of making use of the passage which, from constant employment, had become for them the natural one. In the first and second cases the chief cause of obstruction was laryngeal spasm, but in the second there was also a growth of granulative tissue. In the third case there was a genuine stricture of the larynx, and the tracheal catheter served as a means of continuous dilatation; the result in this case showed that the dilatation should have been employed for a longer period. In two of the cases the tracheotomy incision had divided the cricoid cartilage, and Mr. Pollard suggested that this method of operating might be a cause of the difficulty of re-establishing laryngeal respiration in those cases.—Mr. HOWARD MARSH thought that in performing tracheotomy it should not be forgotten that the trachea was a canal, like the urethra, lined by delicate mucous membrane. Ulceration and granulation tissues were frequently developed under the influence of the mechanical irritation of the tracheotomy tube. The fenestra in the tube was often the offending point, and when situated posteriorly, and then a hernial-like protrusion of the posterior wall might become the seat of granulations. He advocated the use of tracheotomy tubes with movable necks, and with a round, not bivalve, body. The surgeon should have an assortment of tubes to fit different cases, for in some the neck was very shallow, in others very deep, and so forth. He doubted whether all the cases could be successfully treated as Mr. Pollard's, and related a case in which no lumen through the larynx, which was full of granulation tissue, could be detected on examination. Such a case was likely to prove hopeless under any method of treatment. The lapse of time was an important item in the cure of such cases, for cicatrisation might occur meanwhile, and the natural growth and enlargement of the respiratory passages would come into operation. He mentioned a case of stricture of the trachea from permanent contraction which occurred in a child, now a woman aged twenty-five, but without any recovery of breathing power.—Mr. C. H. GOLDING-BIRD considered that Mr. Marsh exaggerated a little the harm done by the fenestra in the tracheal tube. The permanent rough edge of the two-bladed tube was very deleterious. At the present time he had two cases under his care in which the children ceased to breathe on removal of the tube. In these the conditions were probably the same as those he had described in 1885. The edges of the tracheotomy wound were grown upon by granulation tissue. In one case a growth of granulations existed on the posterior surface of the trachea, and this was removed by Toynbee's ear forceps. He did not think the tube would account either for the absence or presence of granulations. A phlegmonous inflammation occurred in some cases, but he could not say whether this had any share in the causation of the granulations. In many the muscles of the larynx wanted treatment, and he thought that catheterisation, which he had practised for some years past, might act by rousing the muscles into proper action.—Mr. R. W. PARKER recognised two classes of cases: those with and those without mechanical obstruction; the former far outnumbered the latter. Treatment by catheterisation for the cases of mechanical difficulty would not always prove successful. Thickening of the mucous membrane of the pharynx and aryepiglottic folds was an important condition not sufficiently recognised. In the second case, he believed that the catheterisation proved dangerous by detaching granulations. In some patients the difficulty remained because the surgeon delayed too long the attempt to remove the tracheotomy tube. He agreed with Mr. Marsh that the tube should be fitted to the case, for the variety in size of the neck, trachea, and child was great. He believed that

Digitized by Google

treatment was not yet entirely successful. Reference was made to a case under his care in a child aged two years, who had scalded his glottis, but for whom little could be done at present, though doubtless time would prove of great service, as it had done, in his opinion, in Mr. Pollard's case, for the larynx remained small till about the age of twelve or thirteen, when an extra development occurred, especially in the male sex.—Mr. BILTON POLLARD, in reply, could not agree that the pneumonia was due to the trickling down of blood, but believed that it was due to collapse of the left lung, owing to the direction of the tube, which perhaps permitted air only to enter the right lung, for there were no breath sounds on the left side of the chest whilst the tube was in. The further progress of the third case was not altogether unsuccessful; many granulations about the vocal cords had by treatment developed into cicatricial tissue, there being a sufficient opening through the larynx to permit of breathing for as long as twenty-four hours, when the tracheal tube had to be replaced, apparently because mucus in the trachea became excessive, and the child had difficulty in coughing this up.

Mr. MERRIDITH read notes of a case of large Omental Lipoma successfully removed by Abdominal Section. The patient, a woman aged sixty-two, was admitted under his care at the Samaritan Free Hospital in January, 1886, suffering from an abdominal tumour of over four years' standing. Some eighteen months before this she had been an inmate of another special hospital in London, where the abdomen had been opened in the belief that the tumour was ovarian, but had been reclosed on the discovery of the fatty nature of the growth. The patient returned home after recovering from this exploratory operation, but remained more or less constantly bedridden on account of the weight and size of the tumour, which steadily continued to increase. On her admission into the Samaritan Hospital, the abdomen, measuring forty-sixth inches in girth, contained an elastic but evidently solid tumour, which filled the entire cavity and overhung the pubes and groins, without invading the pelvis. The growth, viewed in the light of the former operation, was diagnosed as a lipoma of the omentum on the grounds of its comparative mobility and the absence of any intestinal resonance in front of the mass. The tumour was removed on Feb. 6th, 1886, by enucleation *en masse* from its omental capsule. No serious difficulty was encountered, and the abdomen was closed without drainage. The growth weighed fifteen pounds and a half; it was solid throughout, consisting of dense lobules of fat with a scanty amount of fibro-cellular tissue. The patient recovered well, and left the hospital on the twenty-fourth day after operation. She was seen in good health four months later, having gained flesh and strength. Examination revealed no evidence of further growth.

Mr. BERNARD PITTS read a case of Abdominal Exploration for Chronic Intestinal Obstruction, with relief of symptoms by the formation of an Artificial Anus and subsequent removal of Growth involving Splenic Flexure of Colon. The patient, Mrs. D——, came under observation in St. Thomas's Hospital, on August 21st, 1886. She was aged thirty-seven, and had enjoyed good health until Oct. 1885, when the first obstructive attack took place. For the six weeks prior to her admission she had had no satisfactory evacuation of the bowels, even after repeated enemas. She was a thin, pale woman, with distended abdomen, coils to be seen and felt, much peristaltic movement, and occasional vomiting; one large coil was especially marked, running across the abdomen from above downwards towards the left groin. On examination under an anæsthetic, no tumour could be felt, and the rectum was normal. On September 21st, the vomiting became continuous and offensive, and the patient was very exhausted; the vomiting was checked by morphia, but no action of the bowels could be obtained. In consultation with Mr. Edmunds, it was decided to explore the abdomen in the middle line, and this was done on Sept. 24th. The transverse colon was greatly distended and displaced downwards, and the descending colon was completely empty. The end of the transverse colon was attached to a small separate incision in the upper part of the left semilunaris, but the bowel was not opened till several days had elapsed, and the central wound had healed. The patient was in a very depressed state for the week following the opening of the colon. A very large quantity of fæces continuously passed, and she was apparently poisoned by the gases generated during the evacuation. Her breath had a strong fæcal odour; she was for days very drowsy, not recognising her husband, fractious, and suspicious of those around her. After getting rid of the very large fæcal collection she rapidly improved, and was able to get up on Nov. 5th; her weight was then 7 st. 4 lb.; weight before operation, 6 st. 10 lb. By introducing the finger into the colotomy opening, a movable mass about the size of a small orange could be felt under the ribs, evidently a malignant stricture at the splenic flexure. It was therefore decided to attempt the removal of the affected bowel. After careful preliminary treatment this secondary operation was performed on Nov. 22nd. An oblique incision was made on the left side below the ribs, about two inches above the colotomy opening, and by hauling on the collapsed descending colon the affected portion of the bowel was drawn out of the wound, and about four inches and a half excised; several small glands and some adherent omentum were also taken away. The two ends of the bowel were carefully united by silk sutures throughout their posterior and lateral aspects. The muscular coat of this united part of the bowel was then attached by numerous sutures to the abdominal opening, and the everted mucous membrane carefully stitched to the skin. The patient was then left in the condition of possessing a second colotomy opening, the first opening having contracted to the size of the little finger. The patient made a rapid recovery; the temperature remained normal; and on the tenth day she was able to get up. She left for home on Jan. 2nd, wearing a vulcanite tube, with the hope that fæces might pass into the lower bowel and the natural passage be restored. Mrs. D—— was now, five months after the removal of the growth, in perfect health, and able to do ordinary household work. Her weight was nine stone, or a gain of more than two stone since the relief of the obstruction; the bowels were open regularly every morning by the second colotomy opening, but there was complete control for the rest of the day. The specimen, a typical columnar epithelioma of the bowel, was shown and described. Mr. Pitts, in remarking on the case, gave his reasons for making the abdominal exploration, and quoted two other cases of stricture of the large bowel, in which he had made a preliminary abdominal exploration before opening the bowel at a selected position. By the exploration it was possible to gain definite information as to the cause and extent of the mischief, and this was of immense advantage when any further radical measure was contemplated. When no stricture was found in the rectum, he regarded a chance colotomy as an unsurgical procedure. In each of these cases the selected portion of the bowel had been attached to a separate opening in the abdominal wall for three reasons. 1st. It allows the exploration incision to heal by first intention, and as the second opening is exactly the size wanted, and as the bowel is stitched all round, there is no wound near the bowel opening to heal. 2nd. The bowel is not displaced from its natural position by being drawn up to the central wound. 3rd (and most important). It is of great advantage for after-examination to have the opening near the seat of mischief, so that an after-exploration with the finger may determine the character of the stricture and its relations. At the primary exploration, when the bowels are greatly distended, it is well to be content with a very limited examination, and on no account to attempt any removal of growth until all obstructive trouble has been relieved and the bowel has been thoroughly washed out. Mr. Pitts then gave his reasons for not restoring the complete continuity of the bowel at the time of the colotomy, and discussed the chances of successful after-restoration of the natural passage. The paper concluded with some remarks on prognosis and on the poisoning by absorption of gases that occurred during the evacuation of large fæcal collections.—Mr. MORRANT BAKER said that Mr. Pitts' course was exactly what should have been done. An attempt to close the artificial anus might be successful, as in a case of intestinal obstruction which was treated by an exploratory median incision, and in which he made an artificial anus. The main was relieved, but symptoms of septicæmic poisoning occurred after the escape of fæcal matter, similar to what happened in Mr. Pitts' case. The small intestine was opened in this case, the valvulæ conniventes being seen; and later on a prolapse of the bowel occurred, and in reducing this he resolved to carry out a plan of treatment which should attempt to close the anus, for the natural passages had again resumed their function. After incising the edge of the wound in the abdomen he stitched them together, and the wound healed almost throughout its entire length. Such success was as unexpected as it was agreeable.—Mr. A. H.

Digitized by Google

BARKER mentioned a case which illustrated and emphasised the views of Mr. B. Pitts. It was that of a man aged sixty-four, in whom long-continued obstruction, with enormous distension of the abdomen, led Mr. Barker to make an exploratory incision from the umbilicus to the pubes, when a cancerous growth was detected about the splenic flexure in the form of a large mass of hard growth complicated by nodules in the mesentery and parietal layer of the peritoneum. The wound was closed and the right iliac fossa was selected for aspiration, as the cæcum was much distended; this aspiration was repeated several times, with manifest relief, and adhesions formed between the cæcum and the parietes, which ultimately allowed him to stitch the cæcum to the incision made into it with a view to more permanent relief of the symptoms of obstruction. By this method of aspiration a large quantity of feculent matter—three to four pints—was removed, with the effect of relieving distress and causing the sallowness and mental symptoms to disappear. It is now six weeks since the complete opening was made, and the patient was very comfortable. He felt so satisfied that he should adopt the same practice rather than make an opening near the growth causing obstruction. He considered that the artificial anus should be as far away from a new wound as possible. He referred to a case of mental aberration that occurred in a woman after colotomy, which was also relieved by aspiration.—Dr. BROADBENT had observed the curious mental condition in cases of intestinal obstruction without there having been previous operation or any introduction of air into the canal.—Mr. BERNARD PITTS, in reply, said that Mr. Morrant Baker's case, ending in a rather unexpected closure of the artificial anus, could hardly be hoped for in his own case. It was found impossible, owing to the acuteness of the angle at which the intestines joined, either by means of indiarubber or vulcanite tubes, to get the fæces to pass from the upper into the lower part of the united bowel; so that he doubted whether closure of the artificial anus could be easily accomplished. He agreed with Mr. Barker's suggestion that the temporary withdrawal of feculent matter by means of the aspirator would materially help the surgeon to tide over the urgent period of the case. He would prefer that the new wound should be in the immediate neighbourhood of the growth, at least within a reasonable distance—say, from three to five inches.

The following living specimens were shown:—Mr. Victor Horsley: Three cases illustrating Brain Surgery. Mr. R. J. Godlee: Two cases of Abdominal Cyst following injury.

MEDICAL SOCIETY OF LONDON.

Blood Cyst of the Tongue.—Severe Injury of the Wrist-joint, with Division of Nerves, Vessels, and Tendons, treated by Conservative Surgery.—Excision of Nævoid Growth in Neck.—Ossified Epulis.

THE last clinical meeting of the session of this Society was held on Monday last, Dr. J. Hughlings-Jackson, F.R.S., President, in the chair.

Mr. BRUCE CLARKE showed a case of Blood Cyst of the Tongue in a young woman aged twenty-four. The growth was of nævoid aspect; it only began to grow two years ago, and yielded on one occasion serous fluid, and later on only blood, the cyst filling again in five minutes. He proposed to excise the cyst, and if necessary to remove a portion of the tongue. The cautery would probably control any hæmorrhage.—Mr. DAVIES-COLLEY said that blood cysts he had seen were either ordinary hæmatoma or degenerated nævi; he inclined to the latter view of the case shown. A simple plan of treatment would be the use of a ligature. He had successfully treated an extensive lingual nævus by ligatures without the least hæmorrhage.—Mr. F. BOWREMAN JESSETT agreed with the previous speaker; he had seen serious hæmorrhage in treating cases of the kind by ligatures.—Mr. J. H. MORGAN referred to a curious fluctuation in size of nævoid growths.—Mr. BRUCE CLARKE adhered to his own view, whilst admitting the possibility of a nævoid origin.

Mr. WILLIAM ROSE showed a case of Severe Compound Injury of the Wrist-joint. There was a transverse incision dividing all the structures down to the front of the wrist-joint, the median and ulnar nerves, the radial and ulnar arteries, the flexor tendons, and the pisiform bone. The joint was laid freely open. The tendons had retracted, and there was great difficulty in matching them thoroughly, though the nerves were easily found. Immense pains were taken to obtain accurate apposition—end to end union—of the nerve ends. A "tension-stitch" was first used, and then three or four sutures were employed to stitch the nerves together. The posterior interosseous arteries proved sufficient to allow of a flow of blood from the distal ends of the divided radial and ulnar arteries. The treatment was strictly antiseptic. The progress was satisfactory, the joint healing without suppuration. Sensation had returned almost completely. The movement of the wrist-joint was now fairly free. Within one day of the injury there was a return of sensation on the ulnar side of the second finger. He was disposed to break down adhesions under anæsthesia, and to relieve the nerves from their surrounding cicatricial tissues.—Mr. MARMADUKE SHEILD had seen an almost similar case, which he had read before the Cambridge and Huntingdon Branch of the British Medical Association. Primary union of the nerves took place. A glossy skin and bullous eruptions during the winter months were observed. Passive movement and massage were very useful in the treatment.—Mr. BRUCE CLARKE said that it took many months for sensation to return, and it might take more than a year. Careful galvanisation and massage would effect great good.—Dr. ANGEL MONEY referred to the asphyxiated condition met with in cases of peripheral neuritis.—Mr. BERNARD PITTS congratulated Mr. Rose on the result of his conservative surgery. He had treated several cases of injury about the wrist, and had met with some difficulty in "matching" the tendons. An immediate return of sensation might occur within a few hours.—Mr. DAVIES-COLLEY had had seven or eight cases of the kind under his care, though not so severe as in the case shown. He had incised the opening of the flexor sheaths with a view to better finding them. There was no necessity for cutting down on these nerves at present. The interossei did not seem to be wasted. Galvanism would probably prove useful.—Mr. ROSE, in reply, said he intended to employ systematic galvanisation. The improvement had not continued the last two months, and this made him suggest further surgical interference.

Mr. BOWREMAN JESSETT showed a case of Extensive Nævoid Growth, in a young man aged nineteen, situated in the neck about the left ear. At the age of four the growth began to enlarge distinctly. The left ear was greatly swollen and turned forwards by the growth behind. Mr. Jessett attempted to dissect out the whole of the nævus, being fully aware of the nature of the growth. This was found not to be practicable, but the greater part of the growth was removed, with a good result. There was some weakness of the left side of the face.—Mr. WALTER ROSE agreed that it was more scientific and surgical to freely expose the nævus and remove it, rather than to employ subcutaneous methods. Was the pulsation genuine, or merely communicated?—Mr. DAVIES-COLLEY said a large number of these nævi were best treated by excision. In the Guy's Hospital Reports he had described an almost bloodless method of excision. Hare-lip pins were passed crosswise through the base of the nævus, and compressed by means of a drainage-tube twisted round the pins. Pressure by a pad of boracic acid lint was very effectual in preventing bleeding.—Mr. BERNARD PITTS said that excision was very effectual in some cases in the grown-up, but in children the loss of blood and free dissection should be avoided. Nævi that have pulsation at some parts are not very amenable to electrolysis, which was, on the whole, the best method of treating nævi in children.—Mr. J. H. MORGAN had employed Mr. Davies-Colley's method successfully.—Mr. F. JESSETT, in reply, said the pulsation was communicated.

Mr. MARMADUKE SHEILD exhibited a case of Tumour of the Lower Jaw of six years' duration; it was either fibrous or osteoid. The mode of operation might be open to suggestions.—Mr. DAVIES-COLLEY thought it was an ossified fibrous epulis, and he would recommend the removal of part of the alveolar process beneath, in front, and behind the epulis.

ACADEMY OF MEDICINE IN IRELAND.

Resection of the Pylorus.—Œsophagotomy to remove a Foreign Body.

AT the meeting of the Surgical Section held on Feb. 18th, Mr. M'ARDLE read a paper on Resection of the Pylorus, and, as evidence of the importance of this operation, he showed that of 1342 cases of cancer of the stomach, the disease was

Digitized by Google

confined to the pylorus in 802, and of this number 496 were suitable for operation, as there was no implication of the neighbouring gland or adhesion to adjoining viscera. He then detailed a case in which he had removed the pylorus for cancer. The patient died of exhaustion four hours after the operation. He called attention to the result in 70 cases of pylorectomy which he collected: 62 were for cancer, with 35 deaths; 8 for simple stricture, with 3 deaths. The high mortality of the former depended on extensive adhesions delaying the operation. In reference to the question as to where these adhesions most frequently occur, Mr. M'Ardle showed that of 289 cases, the tumour adhered to the pancreas in 132, the omentum in 80, the transverse colon in 72, the liver in 4, and the small intestine in 1. He mentioned that those points of frequent attachment should be taken as landmarks in digital exploration of the pyloric region. The conditions under which he considered operation justifiable were—1. Irritable and intractable pyloric ulcer, leading to spasmodic stricture. 2. Simple fibrous stricture. 3. Circumscribed cancer, without adhesion to the pancreas or transverse colon.

Mr. BARTON read a paper entitled "Œsophagotomy for the Removal of Foreign Bodies." He referred to the removal of a foreign body impacted in the pharynx or œsophagus as a safe and justifiable operation in cases where removal through the mouth was difficult or impossible to effect. He spoke of the reasons which had probably combined to deter surgeons from performing it more frequently, and detailed the case of a child from whom he had removed by pharyngo-œsophagotomy the steel roller of a sewing machine, which had been embedded in the pharynx, opposite the cornu of the hyoid bone, for three months. The foreign body, which was larger in diameter than a sixpence, could be felt in the neck, and was safely and easily removed. The child made a good recovery, the greatest difficulty encountered being the feeding of the patient, which was troublesome, owing to the tendency of food to come through the wound, which did not heal for some time. This was overcome by feeding through a stomach-tube introduced through the wound. Mr. Barton called particular attention to this plan of alimentation, which he considered would prove of much value in the after-treatment of cases of this class.

An Outbreak of Diphtheria.—Notes on Cases of Insanity.

At the meeting of the Medical Section, held on Feb. 25th, Dr. MOUILLOT of Gorey read a short account of an outbreak of Diphtheria which occurred in the female school of the Gorey Workhouse. Eighteen children were affected, and there was a remarkable difference in the severity of the cases. In seven the appearance of the throat was that considered characteristic of diphtheria, and in three of these the local and constitutional symptoms were very severe. In ten cases there was no means of distinguishing the appearance of the tonsils and pharynx from ordinary tonsillitis. In one case the disease appeared to begin in the larynx. Out of the eighteen cases, three had laryngeal diphtheria, with two deaths; two cases were followed by diphtheritic paralysis, and sixteen had distinct enlargement of the cervical gland. Dr. Mouillot traced the disease to a foul smell arising from a choked drain immediately under the schoolroom and dormitory windows. He considered that even the mildest cases were really diphtheria—(1) because all were produced by the same cause, and at the same time; (2) because one of the least severe cases was followed by paralysis of the palate; (3) the cervical glands were enlarged; (4) the children with mild sore-throats were put in the same ward in the fever hospital with the certainly diphtheritic cases, and none of them caught a second attack, though the infectious nature of the disease was shown by a child in another ward, who was convalescent from typhus, catching it. Dr. Mouillot remarked that this outbreak went far to settle the question as to the possibility of diphtheria arising from foul drains, and also was a warning not to hastily decide that any case of inflammatory throat mischief was unimportant and non-contagious if it could be traced to foul drainage.

Mr. JOHN MOLONY read Clinical Notes of cases which he had grouped as fair types of "Fixed Delusions" occurring in various forms of mental disease, and cited in connexion therewith the opinions of Clouston, Spitzka, Savage, and Mickel. He also referred to the habit of alvine evacuation-eating in some forms of insanity, for the purpose of eliciting a discussion on the pythogenic origin of enteric fever, and gave a brief account of circumscribed outbreaks of abortive enteric fever occurring amongst agricultural labourers at "seed-time" employed in manuring, and as a contrast pointed to the apparent impunity with which some lunatics can devour decomposed fæcal matter.—Dr. FOOT suggested that the dirt-eating propensities indicated either what the evolutionists described as the doctrine of reversion, being the return to a degraded state, or that the insane found in it some nourishing food or substance which supplied a want. They showed discrimination by taking the excrement fresh without waiting for fermentation, which was conducive to typhoid.—The PRESIDENT said there were cases of definite monomania which did not last a year, and were curable partly by medical treatment and partly by moral influence before drifting into an asylum, where they were generally incurable. Opium was of great value in soothing the brain when threatened with functional disturbance; while care on the part of friends, and suitable change of scene, often prevented delusions from being stereotyped.

Dystocia caused by Hydrocephalus and Pelvic Tumour.

At the meeting of the Obstetrical Section held on March 4th, Dr. PUREFOY narrated a case of Dystocia caused by Hydrocephalus and Pelvic Tumour seen by him in consultation with Dr. Allen, in which the patient, a multipara, became profoundly prostrate from the suffering due to long-continued but ineffectual labours. The os was found largely dilated, encircling a large mass, which careful examination showed was a hydrocephalic fœtus; below this, posteriorly, was found an oval tumour, very movable and apparently pediculated; this was being driven down before the presenting part during each pain. With considerable difficulty this was pushed up and an opening made in the enormously distended scalp, giving exit to several pints of clear fluid. Even in this collapsed condition the head was so large that it was found necessary to complete delivery with the forceps. When dealing with tumours thus obstructing delivery, if there is reason to believe their contents are fluid, the relative advantages of tapping them through the vagina or through the rectum deserve our particular consideration. — Dr. ATTHILL said he thought the tumour and the hydrocephalic child were mere coincidences. Of course they increased the difficulty of labour, but not the danger of the case. The question was how to deal with a tumour which could not be pushed upwards. His experience was that it was wonderful how these tumours would get out of the way, and how little the patient suffered from their presence. He should have the greatest hesitation in tapping such tumours per vaginam; he thought such treatment extremely risky, because there was a danger of puncturing the vaginal wall.—Dr. LANE asked if the child in Dr. Purefoy's case was alive at the time of the operation. If it were dead, there would have been no difficulty about lessening the size of the head by puncturing it.—Dr. PUREFOY, in reply, said that as to whether the child was alive or not he expressed no opinion; but the likelihood of its being alive might be judged of from the facts that the woman had been for eight or nine hours in a state of horrible suffering before he saw her, and that the child's head contained nearly five pints of fluid. The probability that it was alive was not very great; and it was very unlikely that it would have survived aspiration.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING was held on March 3rd, Dr. Cleaver, President, in the chair.

Hypertrophy of Heart.—Dr. MARTIN introduced a boy aged fifteen with enormous hypertrophy of heart. He had had rheumatic fever two years before. During the past two months he had suffered from continued fever. The area of heart dulness, extending from the upper border of the fourth rib, is four inches and a half in the vertical direction and from the right border of the sternum to a point three inches to the left of the nipple. Mitral stenotic murmur; no aortic. Pulse regular, but weak.

Injury of Popliteal Artery.—Mr. GARRARD read notes of three cases of injury to the popliteal artery, each ending in amputation of the thigh, at periods varying from ten days to thirteen months. First case: Subluxation of both knees; posterior crucial ligament torn off; left popliteal vein torn and artery stretched, rupturing inner coats. Dry gangrene com-

Digitized by Google

menced on ninth day; amputated on tenth; popliteal artery plugged with firm clot at seat of amputation. Second case: A man had a slight sprain of knee six weeks before. Went on working until a large swelling appeared in the ham. When first seen it was almost impossible to distinguish between abscess, aneurysm, and soft malignant growth, but was shown to be a small popliteal aneurysm the size of a walnut, which had been ruptured. There had never been any pulsation in the tumour. Amputated six weeks after the injury. The third case was a severe fracture and bruising of calf, wounding popliteal artery; a false aneurysm was formed and became consolidated, but the limb was useless, and was amputated thirteen months afterwards.

Hodgkin's Disease.—Dr. PORTER showed enlarged suprarenal capsules from a case of Hodgkin's disease. The patient, a woman aged fifty-one, had suffered from enlarged glands on both sides of the neck, the original enlargement, on the left side, occupying most of the posterior triangle. There was also a large mass of mesenteric glands forming an abdominal tumour, and smaller enlargements of the axillary and inguinal glands. The tumour on the left side of the neck had given rise to great pain from pressure up the side of the neck and face and down the left arm, and the external carotid and radial pulses were barely distinguishable. There was also œdema of the left hand, and the arm became ultimately quite useless. One symptom had been flushing and profuse perspirations, at first more or less limited to the left side of the face, due to pressure on the sympathetic. The patient died of gradual exhaustion. At the post-mortem the tumours were found to be entirely glandular. There was some enlargement of the right lobe of the liver and of the spleen, but no lymphoid nodules or bands apparent in either organ. The suprarenals were very large indeed. No enlargement of the intestinal solitary glands was found.—Remarks were made by the President, Mr. Atkin, Dr. Keeling, and Messrs. Jackson and Garrard.

At the meeting on March 17th, Mr. SNELL introduced a young woman with Conical Cornea. In both eyes it involved chiefly the upper part, and in the left especially the cone was very unusually prominent.

Tumour in the Right Iliac Region.—Dr. MARTIN gave brief notes of a case of tumour in the right iliac region, in the neighbourhood of the ileo-cæcal valve, the subsequent course of which seemed to prove that the case was one of fæcal obstruction. Throughout, the bowels were fairly regular, and acted freely under the influence of aperients. It was a month before the tumour disappeared. The general appearance of the patient—a woman aged forty—was strongly suggestive of malignant disease, giving rise to considerable diagnostic difficulties.

Obstruction of the Bowels.—Dr. KEELING read a paper on "The question of Surgical Interference in Acute Obstruction of the Bowels," in which, after limiting the class of cases to which he wished to draw attention, an attempt was made to show: first, that by the use of the statistical method and the bedside observation of certain symptoms, it was possible to arrive at a tolerably exact diagnosis of the cause of obstruction; secondly, that this cause was frequently very similar to what is found in external strangulated hernias, and therefore, thirdly, that the obstruction could be effectually relieved, as in them, only by surgical methods.

At the meeting on March 31st Dr. HARGREAVES exhibited a Dilated Stomach (chronic) after pyloric constriction.

Mr. KILHAM showed two Surgical Kidneys; they contained several abscess cavities, and were from a patient aged seventy-five, the subject of stricture &c.

Mr. SNELL introduced a woman with small contracted pupils, Argyll-Robertson phenomena, optic atrophy, and symptoms pointing to locomotor ataxia.

Double Ophthalmoplegia.—Dr. W. R. THOMAS related a case of double ophthalmoplegia. On Aug. 17th the patient, aged forty-nine, became dizzy and fell, was unconscious for a short time, and when raised it was found that his sight was affected. When Dr. Thomas first saw him in December both eyes were very prominent from paralysis of ocular muscles. There was decided ptosis on both sides. The right eye was immovable, so also was the left; but on the left side there was a decided internal squint. The pupils were not affected by light or accommodation. Objects at a distance could be seen better than those near. Vision on the left side was much more indistinct than on the right. There was no history of syphilis, rheumatism, or cardiac disease, and no previous history of head symptoms. On the whole, Dr. Thomas thought that, as the attack had come on so suddenly, it was due to hæmorrhage pressing upon the corpora quadrigemina on both sides of the floor of the third ventricle and parts around, and that this might be due to pre-existing disease which had not given rise to any evident head symptoms. The patient was improving.

Acute Dilatation of Stomach.—Dr. DYSON related this case. The patient, aged forty-one, was seven months pregnant. A miscarriage occurred thirty-six hours after the commencement of the illness; but beyond increasing the debility and collapse, this did not contribute to her death, which took place on the fourth day after the seizure. The immediate cause of the attack was a draught of cold milk, which was taken after severe exertion. This brought on acute gastric catarrh, accompanied by the vomiting of large quantities of bile-stained fluid and rapidly increasing distension. The physical signs were those set forth by Dr. Hilton Fagge. No post-mortem was obtained. The treatment consisted in giving nutrient and stimulating enemata, stomachic sedatives, bismuth, morphia, &c., and applying a small blister to the epigastrium. Most relief to the pain and vomiting was obtained by hypodermic injection of morphia. The patient was too feeble to admit of the use of the trocar or stomach-pump.—Messrs. Thorpe, Jackson, Baldwin, and Drs. Keeling, Hargreaves, and Martin took part in the discussion.

MANCHESTER PATHOLOGICAL SOCIETY.

AT the meeting on April 13th, the following specimens were shown:—

Malignant Endocarditis and Nephritis.—Dr. H. ASHBY showed the heart and kidneys of a girl aged thirteen years, who had suffered for several years with chronic mitral disease and rheumatism, acute or verrucous endocarditis supervening. A few weeks before her death she had an attack of subacute rheumatism, a diastolic basic bruit made its appearance in addition to the systolic, and the urine was loaded with albumen. At the post-mortem numerous irregular nodules of fibrin were present on the mitral valve and on the posterior wall of the left auricle, and also along the line of contact of the aortic valves. The kidneys were large and pale; microscopically they showed swollen and fatty epithelium, the tubes choked with blood and fibrinous casts. The glomeruli appeared swollen, but were otherwise unchanged. Many of the capillary vessels were choked with emboli consisting of micrococci. The spleen and liver were enlarged.

Cystic Disease of the Kidney.—Dr. H. ASHBY showed for Dr. Macalister the kidneys of a man aged thirty-four years, who had suffered for upwards of three years from epistaxis, hæmaturia, headache, and attacks of dyspnœa. Uræmic convulsions supervened before death. At the post-mortem there was a hypertrophied heart and recent pericarditis. The kidneys consisted of masses of cysts, numbering many hundreds, and varying in size from a pin's head to a marble, their contents were fluid or gelatinous, consisting of altered blood.

Intra-thoracic Tumour.—Dr. HUTTON exhibited a sarcoma involving all the thoracic organs, of a boy of eight years. There had been no symptoms or loss of health until within four or five months of his death, and urgent symptoms existed only for about eight weeks. The growth, arising in the glands, had infiltrated the pericardium, which was in places more than half an inch in thickness, and spread into the lungs deeply in a radiating manner along the bronchi and vessels. Microscopic sections showed it to consist of a felt work of coarse bundles of fibrous tissue containing lymphoid cells in its meshes, with here and there large masses of lymphoid tissue.

Preparation of Œsophagus from a recent case (the Oldham Poisoning Case) of Corrosive Poisoning.—Dr. T. HARRIS showed this œsophagus, which presented a corroded, charred patch, with absolutely black edges; the patch was circular in shape, an inch in diameter, and involved the mucous and submucous tissues. There could be no doubt as to the case being one of poisoning by some corrosive fluid, probably sulphuric acid.

Polypoid Growth of the Vulva.—Dr. BROOKE showed a drawing and sections of a molluscoid tumour of the vulva,

Digitized by Google

involving the clitoris and its folds, both labia majora, and the lower part of the fore-wall of the vagina. The patient, aged twenty-nine, had suffered badly from syphilis for the last eight years in spite of constant treatment. In June, 1885, a "vascular growth" was said to have been removed from the mouth of the meatus urinarius; this, however, recurred and developed into the present condition.

Mr. SOUTHAM and Dr. DRESCHFELD also showed preparations and sections.

Notices of Books.

Food Grains of India. By A. H. CHURCH, M.A.Oxon., F.C.S., F.I.C., Professor of Chemistry in the Royal Academy of Arts, London; sometime Professor of Chemistry in the Royal Agricultural College, Cirencester, &c. Published for the Committee of Council on Education by Chapman and Hall. 1886.—Professor Church, whose claim to attention none will dispute, tells us in his modest preface that his work has been founded on the material collected by the late Dr. Forbes Watson, who for many years worked in this direction. The new analyses contributed by Professor Church are marked by the letter C, but there are so many C's in the book, and many of them are of such interest and importance, that the author might well have claimed a larger share of the honour. The book, a thin quarto, is divided into five parts. Part I. is devoted to the constituents and uses of food. In this part we find clear though succinct descriptions of the carbohydrates, oils and fats, albuminoids, &c., present in all food grains. It was wise to include this description, and it was equally wise to make it short. We notice an unfortunate printer's error on page 5, where the formula for the glucoses is written $C_{12}H_6O_6$, instead of $C_6H_{12}O_6$. Part II. gives a short but very lucid account of the theory of dietaries, in which the heat value and nutrient value are well explained. We especially commend to our readers the figures and arguments on pages 13 and 14, which illustrate, and to some extent explain, the value of "flesh-formers" in muscular work. The curious experiment of Fick and Wislicenus, and the researches which followed from it, caused the real energy value of these compounds to be for a time as much under-rated as they had been before over-rated. The remaining three parts of the book describe respectively the chief cereals, buckwheat, and the allied orders, and the pulses. The seeds of the amaranths possess remarkable food value, the husked seeds of the Bengal amaranth (A. gangeticus) containing 14·5 per cent. of albuminoids and 6·3 of oil, with 2·6 of ash and 61·8 of starch. The high percentage of nitrogenous matter is accounted for by the enormous quantity of nitrates in the tissues of the plant. The dried stem of the well-known "love lies bleeding" will sometimes deflagrate when ignited, and nearly 15 per cent. of nitrates have been found. Throughout the book we find excellent botanical descriptions, and equally excellent illustrative plates. But the most important features are the large collection of original analyses, and the calculations of food value founded on them.

The Diagnosis and Treatment of Syphilis. By TOM ROBINSON, M.D., Physician to St. John's Hospital for Diseases of the Skin. London: J. and A. Churchill. 1886.—The title-page of this little book leads the reader to suppose that he will find the more difficult problems, both of diagnosis and treatment, which arise from time to time in connexion with syphilis carefully dealt with. Such was our expectation in taking up the book; we hoped for some additions to be made to the common stock of knowledge, and we have only to confess to disappointment. The book contains nothing of value that is not found in any good surgical text-book, not to speak of the many excellent works specially devoted to this subject. The history and phenomena of syphilis are dwelt upon with a very light hand, and the rules for treatment are simple—we had almost said crude. The following quotations will show the general style of the work: "I shall abolish the term 'hard chancre,' because its introduction implies that it has some relation to the soft chancre, and I shall use in its place the phrase 'initial lesion of syphilis.' All the symptoms which ensue after the initial lesion I shall include in the terms '*sequelæ of syphilis.*'" Dr. Robinson is physician to a skin hospital, so his views on the cutaneous manifestations of syphilis are especially interesting. Here is one of them: "Does a syphilitic eruption ever assume an eczematous type? Contrary to what we have been taught to believe, I should say—Yes, but only in those individuals who have a skin capable of becoming eczematous." We have only room for two of the therapeutic aphorisms: "I have never seen any reason why Aix-la-Chapelle or any other spa should have any special value in the course of syphilis." "Iodide of potassium to eat up syphilitic manifestations; mercury to prevent their recurrence." We can only add that the style is not improved by the writer changing about between the first person singular, the first person plural, and the third person singular. Such variety is not a literary charm.

De l'Intervention Chirurgicale dans les Affections du Rein. Par AZARIE BRODEUR, M.D. Paris, Ancien Interne en Médecine et en Chirurgie des Hôpitaux en Paris. Paris: G. Masson, 1886.—This is the largest work yet published on the Surgery of the Kidney, and it furnishes the result of an enormous amount of bibliographical labour. Dr. Brodeur has collected from all sources 327 cases of operations performed upon the kidney. The majority of these have been recorded in the medical press, but some of them are new, being taken from the private note-books of Paris surgeons. Not only has Dr. Brodeur collected these cases, but he gives an abstract of each of them. Such forms of statistics have obvious defects; for they show the mortality of the early operations of many surgeons, and of the operations undertaken before experience has clearly indicated the best course to be pursued in individual cases. When full allowance is made for this, however, they are useful, and the author has made up for this defect by the careful and useful abstract of each case he gives. These abstracts, all with full references to the source from which they are derived, will prove to be of very great service to others investigating this branch of surgery, and too much praise cannot be given him for the labour and pains he has taken to make this part of the work complete. The various renal operations are discussed under the heads of the diseases for which they have been undertaken. One fact which has impressed Dr. Brodeur in his study of the matter is the readiness with which nephrectomy has sometimes been resorted to. A study of the work before us will do much to prevent a too frequent practice of the operation.

A Practical Treatise on the Cure of Pulmonary Consumption. By JAMES WEAVER, M.D., L.R.C.P. London: J. & A. Churchill. 1887.—There is no subject in medicine that has been more the sport of credulity than that of the treatment of consumption. The frequent non-success of scientific medicine to arrest the downward progress of the disease has given rise to a host of alleged "cures." Any honest attempt, then, to establish a rational line of treatment is to be welcomed, and so far, in spite of its pretentious title, we are glad to receive the fruits of Dr. Weaver's experience as embodied in this *brochure*. It is, nevertheless, with a sense of disappointment that we find the actual evidence in support of his advocacy of iodide of potassium as the specific for phthisis to be so meagre; and before admitting his conclusions as to the efficacy of this drug we should like to feel persuaded of the share taken in the "cures" by the dietetic and hygienic management on which he [illegible] and rightly lays stress. We are the more sceptic[illegible]

Digitized by Google

the value of the iodide of potassium treatment because of the extremely vague notions which its advocate holds upon the pathology of phthisis. He talks loosely of the enlargement of the "tubercle millet-seed bodies" causing "congestion" and breaking down into cavities; he believes in the unity of phthisis, as well as in its being a "constitutional" disease and as being "contagious"; whilst his ideas of the relationship of the bacilli to the morbid process are so remarkable that we must give the passage entire:—"In pulmonary consumption we are able to demonstrate certain bacilli in the sputa, and although we are at present unable to state positively what the abnormal quality of the blood is which generates this condition of things, we know that this fluid is changed very considerably from that of perfect health, and that its red corpuscles are largely decreased, and that certain other constituents, such as fibrin and lime particles, are considerably increased. It has also been demonstrated that if a portion of blood from a phthisical patient be placed for an hour or two in a warm temperature, certain organisms similar to those expectorated in the sputa are generated and move about in the fluid so experimented upon—going, I think, a long way towards proving that these organisms are first formed in impure blood, and, acting in some peculiar manner on certain portions of lung tissue, cause the probably already deposited tubercular speck to grow and take on organic changes, producing, as already shown, actual consumption." (pp. 17 & 18.)

Traité Élémentaire de Pathologie Générale. Par H. HALLOPEAU. Deuxième édition. Paris: J. B. Baillière. 1887.—This work does not claim to be more than a fairly exhaustive review of a wide subject. In it are to be found the results of investigations carried on in all countries, and collated by M. Hallopeau with exemplary diligence. The subject matter is divided into five parts. The first treats of etiology, discussed under the heads of intrinsic and extrinsic causes, the latter including, of course, the subject of micro-organisms, which is treated with considerable fulness. The second part deals with morbid processes, commencing with inflammation and ending with tumours. The third part is concerned with symptoms, each system of organs being taken in turn. In the fourth part, the subject of disease as a whole is discussed, and in the fifth the general principles of therapeutics; but these are comparatively sketchy, and not equal in depth of treatment to the rest of the book. As a whole, the work is one which will be appreciated as giving a faithful account of present knowledge of the processes of disease; and to the student desirous of reading a French work we can heartily recommend it. The systematic method upon which it is planned, and the care which the author has expended on its revision, are worthy of commendation.

A New Clothing Case for the Soldier. By W. THORNTON PARKER, M.D., A.A. Surgeon, U.S. Army. Pp. 15. Newport, R.I.: Davis and Pitman. 1887.—This pamphlet is another attempt to solve the much-vexed question how a soldier on the march can best carry his service kit. Dr. Parker proposes to abolish the knapsack in use in the American Army and to substitute for it a case made of light canvas, rubber cloth, or waterproof cloth, divided into three equal pockets, and to be worn over the left shoulder. It is claimed for this that it will be lighter than the knapsack, and the weight be more equally distributed; but we are by no means sure that, in the summer especially, the soldier would not suffer more from the heat of this case, before and behind, than he would from the slight additional weight of the valise now in use in our service. The pressure of the case, also, on the front of the chest would probably be found to impede the respiration in the same manner, though not in so great a degree as the belts of the old knapsack, now happily abolished in the British Army. These are points, at least, which should be determined by careful experimental trials before any change is taken into consideration.

Causeries Scientifiques. Par HENRI DE PARVILLE. Paris: J. Rothschild.—This is a medium-sized volume, containing an account of recent discoveries and inventions, given in a pleasant, readable form, but of necessity much condensed. There is a mass of interesting material in the book, embracing a wide area. M. de Parville devotes some chapters to public hygiene, physiology, electricity, geological and meteorological discoveries, and other subjects too numerous to specify. Inoculation for cholera by Ferrán is discussed by the author at some length. He is of opinion that the judgment with regard to the efficacy of the treatment passed by the French Committee of Inquiry was too hasty. Although it appeared that Ferrán was unable to cultivate the cholera bacilli virus, there is still no reason, he considers, why the germ of truth contained in the idea of inoculation for this terrible disease should be disregarded. It remains for others to develop this theory, which M. de Parville thinks may be of importance to the human race. Several pages are devoted to hypnotism and other psychical experiments. Suggestion, M. de Parville remarks, would explain more than one miracle and many mysterious recoveries. As a popular or semi-popular year-book of science this work may be regarded as a valuable little book.

Variations of Fortune. Illustrated by Sketches of some of the Old Towns of Italy and of those who influenced them. London: Sampson Low. 1886.—"Everyone," says Goethe, "finds in Rome exactly what he brings to it"; and from Rome the saw might have been extended to Italy. It is to furnish the English-speaking visitor to the antique and mediæval treasures of the Italian peninsula with some preparation for the better appreciation of what he sees that this portable little volume has been written. Already favourably known to the artistic world for her beautiful drawings of the "Seven Ages of Man" from the pavement of Siena Cathedral, the authoress has applied her draughtsmanship to the reproduction of some of the most characteristic scenes and figures of Italian history; and, in conjunction with the skilful letterpress that leads up to and explains them, she brings before the reader, in a vivid and memorable way, a series of most interesting events and achievements, making the realisation of them on the spot at once easy and delightful. Those of the profession who contemplate a holiday in Umbria or the Roman territory could not do better than take this little volume as their companion.

The Medical Annual. 1887. Bristol: John Wright and Co.—The publication of this work has been a little delayed owing to the unavoidable increase of matter and the number of pages found necessary to carry out the work efficiently. Its scope, however, has been so extended as to render it a complete work of reference on the modern treatment of disease. The Dose Index has been much enlarged, and the section "Books of the Year" has been extended by the addition of the more important American works published during 1886. The current volume is a distinct advance upon its predecessors, and can be unreservedly recommended to practitioners who desire a source of ready reference on questions of therapeutics, &c.

Street's Indian and Colonial Mercantile Directory. 1886-87. London: Street and Co.—In addition to the trade returns, tariffs, populations, &c., of the various colonies which are dealt with, this volume contains alphabetical lists of the leading professional men and merchants in the different towns, concise descriptions of each country and town, with the view of showing their commercial capabilities and peculiarities, and particulars of the various railways in operation or in course of construction. The amount of information contained in it is enormous, and the

Digitized by Google

work, which contains nineteen maps, will be appreciated by all who take an interest in and desire information respecting our colonies.

Analytical Records.

THE GERMAINS IMPROVED APPARATUS AND POWDER FOR DISINFECTING AND FUMIGATING.

(A. Z. GERMAINS, WINDSOR-ROAD, VICTORIA-PARK, LONDON.)

THE apparatus is a small metal hearth with a false bottom and side holes, to admit air. Over this is a hood with a side pipe near the top, by which fumes can escape. The powder contains sulphur, and burns easily. Mr. Germains has certainly contrived a convenient and safe method for sulphur fumigation, but every such contrivance is liable to be misused, and some of the statements made by the inventor are likely to lead to very dangerous misuse. Our readers know well that serious disinfection cannot be accomplished by the production in a room of a mere smell of sulphurous acid or any other chemical agent. To disinfect with sulphur one pound must be burned to every 1000 cubic feet, and the exposure must last many hours. Real disinfection by this machine in the presence of living creatures would be impossible; and when the inventor talks of the purification of churches he talks nonsense. Such a fumigation would have no real value, and would be dangerous as leading to a false sense of security.

MOUILLA, OR POTASH LIQUID SOAP.

(M. R. EDWARDES, ADAM-STREET, STRAND.)

This interesting soap is the invention of Dr. Duncan of St. Petersburg. We find by analysis that it is, as described, a potash soap containing glycerine, and scented with lemon. It is a clear solution, which mixes easily, and gives a lather with soft water. Opinions may differ as to whether potash is better than soda soap for ordinary use; but if potash soap is wanted it could not be obtained in a more convenient or elegant form. For medical purposes the soap is incorporated with small quantities of carbolic acid, Russian birch tar, and other substances. The carbolic soap, in particular, is a useful and valuable preparation.

BOKÖL, A NORWEGIAN PREPARATION OF MALT.

(DAVIS, BERGENDAHL, & CO., NEWCASTLE-ON-TYNE.)

This is a liquid alcoholic preparation which tastes like sweetened beer. It might, perhaps, be used with advantage instead of stout, but, as it possesses scarcely any diastasic power, we cannot recommend it as a substitute for malt extract.

KENTISH SAUCE.

(BURGOYNE & CO., PERCY-STREET, TOTTENHAM-COURT-ROAD.)

All that we need say of this sauce is that it is pleasant in flavour, and that our analysis shows that it is entirely free from poisonous metals.

LIQ. PODOPHYLLIN (HOCKIN).

(HOCKIN, WILSON, & CO., DUKE-STREET, MANCHESTER-SQUARE.)

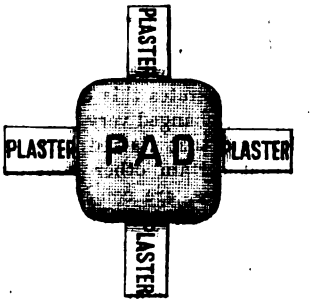
This seems an excellent extract. It is faintly alkaline, mixes well with water, alcohol, dilute acids, and small quantities of alkaline carbonates, but is precipitated by alkaline hydrates.

VAN ABBOTT'S BEEF-TEA.

(G. VAN ABBOTT & SON, LONDON.)

This is a stiff jelly easily soluble in warm water. The solution contains no fat or albumen, and may therefore be boiled. In flavour it is excellent, and we have no hesitation in awarding it high praise.

RAPHAEL TANNIN WINE.



(M. GALLAIS, PICCADILLY.)

A full-coloured, luscious, and agreeable wine, faintly acid and remarkably astringent. The iron and gelatine tests show the presence of a considerable proportion of tannin. We think [illegible] useful in [illegible]

New Inventions.

SELF-FIXING ABSORBENT PADS.

MR. DE ST. DALMAS, of Leicester, has submitted to us one of his "self-fixing absorbent pads." It consists of a pad of absorbent wool enclosed in thin muslin, with four "tails" of St. Dalmas strapping affixed to it. The pads are

made of various sizes, and can of course be easily prepared impregnated with an antiseptic. The woodcut shows at a glance the mode of application.

AUTOMATIC PURIFYING CLOSET.

AN ingenious method of dealing with excreta has recently been patented by Messrs T. Goddard and Co., of Queen Victoria-street, which claims to be an improvement upon the earth-closet. The material used in substitution for earth is called "sanitary carbon," but there is no statement of the source from which this carbon is derived. Its action upon the excreta is that of an effectual deodorant, and it has the advantage of retaining the ammonia, thus producing a manure which must have some value. It is used in connexion with closets and commodes provided with lids which are charged with this material. On shutting down the lid a sufficient quantity of the carbon is scattered over the excreta in the pan beneath, rendering them entirely free from smell; and it is said that the amount of earth or ashes commonly required for this purpose is five times that of the carbon, the cost of the quantity of the latter material sufficient for each time of using being one-eighth of a penny. It is probable there will be some demand for the use of this deodorant in places where the water-carried system is impossible.

MEDICAL ATTENDANCE ON THE POOR.

To the Editors of THE LANCET.

SIRS,—I am obliged by your remarks, and the attention you have given to my pamphlet on Medical Attendance for the Sick Poor not Paupers; but I regret if I have at all led you to infer (and I appear to have done so by your closing remark) "that I said the object sought by Sir Spencer Wells' committee was only for the benefit of the poor and not the industrial classes." Now by the very title I gave my paper it was my desire and intention to show that it was in the hope of providing, as I particularly mentioned in my pamphlet, kind and efficient medical aid for this section of the general practitioner's patients that this committee was now sitting, and I think I specially implied this by mentioning that I advocated that the wage limit should in certain cases be extended (as to men with large families) even to £6 per week by paying 10s. per month when in health. What I did mention was that Sir Spencer Wells' committee was not organised for relieving any class who were well able to pay our usual fees, nor for that upper stratum of the industrial classes "whose annual [illegible] very often was much larger than that of the average clerk and even nearing a not small number of the professional classes." I am, Sirs, your obedient servant,

April 18th, 1887. [illegible]

THE LANCET.

LONDON: SATURDAY, APRIL 30, 1887.

THE American Public Health Association has made an important contribution to the subject of the danger attaching to rags as disseminators of disease. In a report of a Committee on the Disinfection of Rags, they have embodied a summary of the principal information available as to the possibility of the communication of disease by means of rags, and of the circumstances under which such communication takes place. In this country the two diseases which are most in question in connexion with rags are small-pox and cholera. As regards small-pox, it would be mere waste of time to make any endeavour to prove that the infection is conveyed in old clothing and rags, for the positive evidence on this point is overwhelming. So many outbreaks of small-pox have occurred amongst rag-sorters in paper-mills, that the only point of real importance which remains for discussion is how far this source of infection can be stayed. In an able letter appended to the report, Dr. STERNBERG, of the United States army, who has devoted much attention to the subject, evidently inclines to the view that since we have in vaccination an efficient means of protecting people, whether rag-sorters or not, against small-pox, it would not be justifiable to place any substantial hindrance in the way of a trade involving such large interests as that of paper-making from rags. But he holds that where a health officer has special reason for regarding any bale or consignment of rags as infected he should take the needed precautionary measures. In England even this limited action would be difficult of application, because, unless it can be shown that a definite consignment has actually been exposed to infection, the 126th section of the Public Health Act (1875) becomes practically useless. And even where such exposure can be proved, it is a difficult task effectually to disinfect a bale of rags unless a high-pressure steam apparatus is available. The alternative, indeed, would be the destruction of the bales, with compensation to the owner, under Section 121 of the Act, on the ground that the process had been carried out in the interests of public health.

Turning next to cholera, the report must be taken as setting at rest all doubt as to whether the infection of this disease can be communicated by means of clothing and rags. The number of cases cited in proof of such communication is so large that, even allowing for sources of error which might attach to some of them, there still remains a sufficient body of evidence to answer all reasonable purposes, and to justify the action which is adopted by our Government, and by most other European Governments—namely, the absolute prohibition to import rags from countries where cholera is prevailing. But the instances cited, taken along with the comments of Dr. STERNBERG, go to show that, after all, it is not so much rags, as such, that constitute the source of danger, as small parcels of clothing, over the transit of which our Cholera Orders in all probability exert no influence whatever. Rags, it appears, are gradually collected at the ports whence they are shipped; they are sorted, and put together in bales by local people, and yet it has been most difficult to show that cholera has been distributed through the agency of such establishments. And so slow is the system of accumulation at times that rag-vendors can allow their stores to increase until the prohibition is removed; and, after all, the very rags which it was sought to keep out of the country reach it at a somewhat later date. Here, however, comes in an important question. How long does the infection of cholera retain its vitality in rags and in similar cargoes? Probably for a limited period only, when compared with that for which the small-pox virus remains operative for mischief under similar circumstances. But even with these limitations to absolute certainty as regards the importation of the disease, we agree with the reporters that Governments have no alternative but to prohibit, during cholera epidemics, the importation of rags from ports neighbouring to the districts affected.

Dr. H. B. BAKER, the secretary to the State Board of Health of Michigan, is evidently inclined to suggest such wider action as would deal with rags imported from places where scarlet fever and diphtheria prevail. He begins by pointing out that the mortality occasioned by these diseases is vastly in excess of that from small-pox or cholera; and as regards the former, he says that whereas the small-pox deaths in the United States in 1880 numbered only 874, scarlet fever killed 16,416, and diphtheria 38,398. That the contagia of both these diseases can be communicated by means of rags, which are so largely made up of old clothing, admits of no doubt; although in the case of diphtheria the instances which go to prove it are by no means so numerous as in the case of scarlet fever. But with these diseases so rife as they are both in England and in the United States, and with infection spreading daily through our schools and other agencies, we think it would be most difficult to induce any Legislature to go beyond provisions such as are included in our Public Health Act and which limit preventive action, under such circumstances, to cases in which it can be shown that there has been actual exposure to infection.

Another alternative has been suggested as regards all the more dangerous contagia liable to be communicated through rags, and which, in addition to cholera, small-pox, scarlet fever, and diphtheria, include such affections as typhus, yellow fever, anthrax, and pleuro-pneumonia. It is that at all ports or at all paper-mills the rags should be disinfected. Both Dr. STERNBERG in America and Dr. PARSONS in this country have shown that, so far as the actual process of disinfection is concerned, this can be effected by steam-pressure disinfecting machines; but some of the paper manufacturers declare that the rags are injured by the process, and since vaccination is available against the contagium most commonly in question, it has never yet been regarded as practicable to impose the suggested restriction. In the meantime health officers should exercise the greatest vigilance in the case of the importation of rags, whether by sea or land; and, in the case of cholera, prohibitions to import must evidently be continued.

WHETHER regarded from a public health, or from a political point of view, the paper recently read by Mr. NOEL

Digitized by Google

A. HUMPHREYS before the Royal Statistical Society has served a useful purpose in calling attention to the wide variations between the mortality of different social classes.

The necessity for further and more accurate information on the subject is clearly shown, but our present knowledge warrants the conclusion that the future of health progress depends mainly upon the successful application of sanitary reform to the homes and manner of living of the working classes. How far it may be admissible to judge of the effect of class influences upon mortality in England from Dr. GRIMSHAW'S Dublin figures must remain a moot question until similar statistics are prepared for English populations. The fact, however, that the mean duration of life by ANSELL'S Upper Class Life Table is fifty-three years, instead of forty-four years by the most recent national life table, affords conclusive proof of a far wider difference existing between the rate of mortality of the upper and of the working classes. While, however, it is highly important that the excess of mortality in the artisan and labouring class should not be lost sight of, it is fully as necessary to remember the facts and figures set forth by Mr. HUMPHREYS to prove that high death-rates are not the inevitable and necessary fate of this class. In the absence of any trustworthy English working-class mortality statistics we are obliged to fall back upon the Registrar-General's Occupational Mortality Statistics, which certainly do not justify the sensational assertion of an evening contemporary, that the "work of the learned professions conduces to life, and that of the artisans to death." The near approach of the mortality of labourers in agricultural counties and of gardeners to that of the clergy, which between twenty-five years and sixty-five years is represented by 556, as against 1000 for the mortality of all males, was pointed out in the paper. It is necessary, however, to call attention to the fact that the relative mortality figure for lawyers is 842, and for medical practitioners 1122; and also to point out that below or between these figures come wheelwrights, 723; carpenters, 820; ironstone-miners, 834; coal-miners, 891; plasterers and whitewashers, 896; shoemakers, 921; bricklayers masons, and builders, 969; blacksmiths, 973. The mortality figure for each of these groups of artisans is below that for all males, and very considerably lower than that for the medical profession, while the mean mortality of all the groups but slightly exceeds that of the legal profession. Whatever may be the explanation of these apparent anomalies, it is at any rate clear that the work of the medical profession can scarcely be said actually or relatively to conduce to long life. It is quite possible to believe that an artisan's life, with actually shorter hours of work and far less mental worry, may in a large proportion of cases be more conducive to longevity than that of the professional man. It is the general and unskilled labourers in towns who suffer most, and who from their numbers tend to raise the mortality of urban populations.

The most important political, social, and sanitary problem of the day now urgently calling for solution, is to devise means for preventing the accumulation of unskilled labourers in towns in sanitary condition and surroundings not only fatal to themselves, but a source of real danger to the physical, moral, and social health of the nation. There can be no doubt that the manner of living of the poorest classes in certain portions of most of our towns constitutes a source of danger to the public health, while we see its result upon themselves and their children in the statistics given in Mr. HUMPHREYS' paper. It is asserted by owners of house property and by sanitary authorities that they are helpless to control the home surroundings of these classes; but if landlords were held more distinctly responsible for the sanitary condition of their underlet tenements, such a pressure would be put upon the tenants as would teach them the necessity for decent living. In this way a civilising influence would be brought to bear forcibly upon the class, and the benefit to the public health would soon exercise an appreciable influence upon the death-rate. The effect of such pressure upon the mortality from zymotic disease may be estimated from the variations in the death-rates from these diseases in the various social classes derived from Dr. GRIMSHAW'S figures. We learn that in Dublin, after correction for variations of age distribution, measles mortality was during the three years 1881–83 nearly ten times as fatal in the general service class as in the professional and independent class; whooping-cough more than four times as fatal; scarlet fever more than twice as fatal; typhus nearly five times as fatal; and diarrhœa nearly three times as fatal. Experience points to the homes of the working classes as the usual generating ground of most of these zymotic diseases, from which the middle and upper classes derive the infection. With cleaner and healthier homes for the working classes, and with increasing difficulty put in the way of those who are now said to prefer unwholesome surroundings, it would be safe to calculate upon a further rapid decline of zymotic mortality in towns. It is beyond doubt that the decline of zymotic mortality in recent years has been one of the most potent factors in the reduction in the death-rate of children.

Notwithstanding this marked decline of child mortality, the strongest contrasts between the death-rates of different social classes are still found to prevail during the ages of infancy and childhood. Thus, it was pointed out by Mr. HUMPHREYS that the mean annual mortality under five years of age is just five times as great in the general service class (the class of general labourers below the artisan class) as in the professional and independent class; while at the next age period, five to twenty years, the difference between the mortality of these two classes is very nearly as great. It is true that the rates of mortality in adult life are more than twice as high in the general service as in the professional class, but it is fair to assume that some of this excess of mortality in adult life is rather due to the depreciating constitutional effect of insanitary surroundings and hardships in childhood, than to occupation and the other conditions of adult life. How far the conditions which lead to the terrible waste of life and health among the children of the poor are within control cannot be easily decided. When, however, due note is taken of the marked reduction of working-class mortality, especially among infants and children, in the Peabody and other improved dwellings, undeniable proof is supplied of at least one direction in which effective sanitary checks may be applied to the waste of child life, which we are too apt to regard as inevitable and beyond control. Is it necessary to urge the courageous application of this

Digitized by Google

form of control, without any cynical dread that decline in the death-rate will only lead to such an increase of population as will add to the social and political difficulties arising from over-population?

In conclusion, it is worth noting that the proportion of children in the several social classes is constantly in inverse ratio to the capacity of the several classes to support their children in a manner to favour their becoming, physically and morally, healthy members of society. It appears from Dr. GRIMSHAW'S classification of the Dublin population that 1000 of his professional and independent class contains only 75 children under five years of age, while the same number of the artisan class contains 121 children of those ages. It should be remembered, too, that these proportions under-state the relative proportion of children born in the artisan class, on account of the far higher death-rate among children in this class compared with that which prevails in the professional and independent class. Who can decide how much of the poverty and its attendant high death-rate and disease is due to the improvident and far too early marriages among the working classes? Let us hope that the recent decline in the national marriage-rate and birth-rate, which has been almost as marked as that of the death-rate, instead of being entirely due to commercial depression, may in part be attributed to a form of national prudence and thrift, which may not be without its effect upon the death-rate of children, and will certainly moderate the rate of increase of population, which, in some quarters, is viewed as a source of political danger.

BETTER explanation has long been needed of the circumstance that in every outbreak of disease due to infected milk some only of the milk drinkers have been attacked, while others, and that often a large proportion, have escaped. This unequal incidence of attack is doubtless due in part to a difference in the susceptibility of individuals, but this has long been seen to be insufficient to account for the facts observed. Quite recently Dr. KLEIN, in his report on the etiology of foot-and-mouth disease, commented on a "very puzzling" point which was observed in the feeding of certain sheep with the streptococcus of this malady—viz., that the process had to be repeated three times before one of them became infected; and he referred his readers to experiments made some years ago by Dr. BURDON SANDERSON and Mr. DUGUID, who found it necessary to rub hay steeped in the saliva of a diseased cow several times over the mucous membrane of the mouths of the animals which were the subjects of his experiments before the infecting process was complete.

Mr. W. H. POWER, in his report on the recent outbreak of diphtheria at Yorktown and Camberley, which the Local Government Board have just issued, has thrown considerable light on the conditions which affect the capability of milk to produce disease. It is necessary to refer briefly to the main facts contained in Mr. POWER'S report to enable his argument to be understood. The inquiry, it will be recollected, resulted from the desire of the inhabitants of the invaded locality to have further investigation of an outbreak which the local medical officer of health had attributed to infected milk—a conclusion which Mr. POWER fully confirms. The possibilities of drainage, water-supply, and deposits of river mud being concerned in its production were fully examined by Mr. Power and set aside, as well as all chance of articles of food other than milk being implicated. The evidence that milk was responsible for the occurrence is to be found in the fact that in a given area containing 176 houses, 94 of which received milk from the infected farm and 82 of which derived their supply from other sources, 48 of the former and but 9 of the latter were invaded by diphtheria or throat illness, and the inmates of some proportion of these 9 houses had either been exposed to infection from other cases of diphtheria, or had, away from home, consumed some of the suspected milk.

The chief interest in Mr. POWER'S story lies in what follows. The milk drinkers did not receive the same quantities of milk. There were, in fact, in this locality two classes, a rich and a poor; the former, who were supplied with larger quantities, suffering from threefold to fourfold as much as the latter, whose use of milk was limited to its consumption in tea. Mr. POWER shows that the number of opportunities for infection in one and the other class were practically forty in the richer to twenty in the poorer; but the difference observed in the incidence of the disease was even greater than could be explained by any consideration of the quantity consumed, and even amongst households alike receiving large quantities of milk there was an unequal incidence of diphtheria in accordance with the manner in which the milk was treated. In certain households it was the custom to "set" milk for cream, and the skim milk which thus came to be subsequently consumed was evidently responsible for an exceptionally large amount of diphtheria amongst its drinkers; cream itself did not appear to give rise to increased illness, for although families receiving cream direct from the dairy suffered heavily, they were, it is noted, those who consumed large quantities of milk, and they did not suffer more severely than other families, also large milk drinkers, who were not supplied with cream. One other point of interest is dwelt upon in the report: the quantity of milk consumed by individuals who were infected does not appear to have had any influence upon the severity of their disease when judged by the number of severe cases which occurred amongst the total number attacked, for two-thirds of the attacks among large consumers of the milk and one-half of the attacks among small consumers were severe—a difference, as Mr. POWER observes, not sufficient to connect intensity of attack with the amount of milk consumed.

The investigation failed to show the manner in which the milk acquired its infective property. There was no opportunity, as at Hendon, for comparing the relative infectiveness of milk from one cowshed and from another, for the milk of all the cows on the farm was intimately mixed before its distribution. That it was infective before leaving the farm is proved by the fact that it was distributed on four milk-walks, and each supply produced the same result. So, again, no explanation could be found for the circumstances under which cessation of infectiveness occurred, for the reason that nearly all the farmer's customers left him when the disease became prevalent.

The best use has undoubtedly been made of the opportunity for inquiry, and some lessons learnt which ought to be turned to practical account by those upon whom devolves

Digitized by Google

the duty of dealing with milk, both before and after it is supplied to a household. We fear it will be long before the necessity for boiling milk is generally recognised by those who are still unwilling to adopt this simple precaution; but the teachings of Mr. POWER'S report are worthy of serious consideration—that the amount of risk from drinking infected milk depends upon the manner in which it is treated after its entry into a house.

IT almost seems as if there was a slight abatement in the rush into the medical profession. Whether young men are deterred by fear of the examinations, which have been growing in stringency or of the increasing cost of medical education and examination, or by the prospect of poor pecuniary rewards, we cannot say. But there are some indications in the newly issued "Medical Students' Register" of more caution in entering on medical studies. This annual publication[1] of the Medical Council contains a good deal of interesting information. It gives the list of examining bodies whose examinations meet the requirements of the General Medical Council in Preliminary Education. Another list of great interest is that of the Places of Medical Study whereat students were registered in England, Scotland, and Ireland, and in India and the colonies respectively. On another page the regulations of the Medical Council are given for the examination and registration of medical students. Then there is the Register itself—for medical students have their register as well as medical practitioners.

The chief points of interest to us are the summary of the numbers commencing the study of medicine in each of the three divisions of the kingdom and the list of the chief seats of medical study. On page 12 is a table giving the number of students registered during each year from the commencement of students' registration in 1865 to the end of the year 1886. The number of students registered as commencing their studies last year was 1904—quite enough, it might be thought, to supply an annual waste by death of 600 or 700. As we know, there is a great falling off in these when the examinations are reached, and, roughly speaking, little more than two-thirds ever enter the profession. But what we notice is that if we compare the numbers registered as commencing study in the last five years with the numbers in the preceding five, there is an actual falling off. Of course from year to year the number fluctuates. But we find the number in the five years 1877 to 1881 to be 9669, or an annual average of, say, 1934; whereas, in the five years 1882 to 1886 the number was 9390, or an annual average of 1878. In the first quinquenniad the number exceeded 2000 in three years, the largest number being in 1881, 2171; whereas in none of the last five years did the number reach higher than 1957. There need, however, be no fear of an abundant supply to meet the waste of the profession; for the average mortality of the profession, though larger than it should be, is scarcely found to exceed for the last three years 600, whereas the average actual registration of practitioners on the Medical Register for the same years is 1373. This influx of double the number that are lost to the profession by death affords some explanation of the excessive competition which obtains in many parts, and leads to occasional breaches of those traditions as regards professional conduct which have long regulated medical men in their intercourse with each other, and in their bearing towards the public. An excess of over 700 a year may well lead those who think of entering the profession to pause. If they do so from the love of it, well and good; but those who wish for an easy road to fortune will do well to seek some other way.

The chief seats of medical study come out in the list of schools. The commencement of medical study by *pupilage* to a practitioner obtained in 177 cases—namely, 142 in England, 4 in Scotland, and 31 in Ireland. Besides these instances, many date the commencement of study from a provincial hospital. Of the 1908 students registered in 1886, 915 were registered in England, 626 in Scotland, and 367 in Ireland. The London schools scored 433 of the students, the Edinburgh University 280, and that of Glasgow 137.

A MISUNDERSTANDING, at which no one can wonder, has arisen between the two well-known engineers, Sir JOSEPH BAZALGETTE and Mr. BAILEY DENTON. Considering how diametrically opposed their views on sewage disposal have always been, it would be strange if they did not sometimes mis-read each other's words. Sir JOSEPH, in his evidence before the Select Committee of the House of Commons on the Pollution of the River Lea, advised that the sewage should be treated chemically as at Crossness, but with a considerably larger proportion of chemicals. As the sewage is to be discharged into the Thames at a point about one mile from the Barking outfall, and as therefore it is only the Thames that can be injured, it is certainly difficult to understand why the treatment considered sufficient for Crossness and Barking should not be sufficient for the Lea valley. In Sir JOSEPH'S opinion the more moderate system, which has been tried on a large scale and is about to be adopted at the great outfalls, is not only sufficient but "very satisfactory." He only advised the more expensive system, it appears, in deference to the opinions of others and to "conciliate opposition." Sir JOSEPH evidently thinks now, as he has always thought, that all this talk about river pollution and sewage disinfection is mere nonsense, that raw sewage does not pollute the Thames, and that Mr. DIBDEN'S valuable and carefully executed experiments at Crossness are quite unnecessary. He expressed his opinion that the chemicals used will soon be curtailed in quantity, and perhaps believes that they will before long be dispensed with altogether.

It is needless to say that we dissent entirely from the views to which the Metropolitan Board of Works has most unfortunately committed itself. The Board has done great and good work for London; and the drainage of the metropolis, accomplished by the skill of Sir JOSEPH BAZALGETTE, has been one of the greatest of its labours. But Londoners cannot cease to resent the injury done to their river, or the obstinate and persistent manner in which that injury has been defended. It is true that, tardily, reluctantly, and under compulsion, the Board is preparing at great cost to diminish the evil, but they do so with the worst grace and in the worst way. Their new works, executed in defiance of the unanimous advice of Lord BRAMWELL'S Commission, involve enormous expense, and cannot settle the question. We do not object to the works, which, as far as the limited

[1] To be had of Spottiswoode and Co.

Digitized by Google

nformation afforded to the public enable us to judge, appear well designed, but we must once more object most strongly to their site. Everyone except the Board and its immediate supporters is convinced that the sewage of London can only be properly disposed of at a much greater distance from the City than at present. All the expense about to be incurred at the Barking and Crossness outfalls, including the steamers required to carry the sludge to the sea, will, we are certain, be found after a very short time to have been money wasted through mere blind obstinacy.

Annotations.

"Ne quid nimis."

NEW REGULATION OF THE EXAMINING BOARD OF ENGLAND.

AT a meeting of the Committee of Management of the Examining Board in England of the Royal Colleges of Physicians and Surgeons on the 25th inst., it was resolved: 'That to enable students who commenced their professional education before Oct. 1st, 1884, to pass a qualifying examination for the purposes of registration, students who shall have completed four years of medical study to the satisfaction of the Committee of Management, and who shall have passed such first and second examinations as that Committee shall approve, may be admitted to the final examination of the Examining Board in England, which is a 'qualifying examination' for the purposes of registration under the new Act." Students desirous of taking advantage of this resolution of the Committee of Management must make application, in writing, to the secretary of the Examining Board in England, giving full particulars of any examinations passed by them at the two Colleges or elsewhere. This regulation is obviously of the greatest importance to students who have passed the first and second examinations under the old regulations at either of the two examining bodies.

THE SCOTTISH UNIVERSITIES AND REPRESENTATION IN THE GENERAL MEDICAL COUNCIL.

ONE of the warm questions in the Scotch Universities is that of the right to elect representatives in the General Medical Council. Hitherto the Senatus has assumed and exercised the power of electing the representative. But a powerful and somewhat pugnacious party exists now which claims the right and power of electing for the Council of the University. Our readers will remember that this subject was raised by Dr. McVail at the last meeting of the Medical Council, and that he challenged the validity of the election of the Scotch University representatives returned by the Senatus of their Universities. The question has been raised in the Council of the University of Edinburgh, on a motion by Mr. Vary Campbell reflecting on the Senatus for illegal action, and asking for a clause in the University Bill to secure the right of election for the Council. Sir William Turner warmly resented the censure of the Senatus, and insisted that any alteration of the law should be in the shape of an amendment of the Medical Acts, rather than in the University Bill. He carried an amendment asking that the consideration of the interpretation of the Acts bearing on the question be referred to the University Court. Whatever may be the truth in this dispute, we caution reformers against expecting any speedy relief from a reform of the Medical Acts. Statesmen have had enough of Medical Acts lately, and have ended in a very poor legal achievement; they will not, therefore, be likely to meddle with the subject again in a hurry.

RELATIONS BETWEEN THE THYROID AND CEREBRAL CIRCULATION.

THE impetus which the description of the condition known as myxœdema has given to the study of the thyroid gland has received an additional illustration in a note by Professor Waldeyer (*Berl. Klin. Woch.*, No. 14), calling attention to the arterial supply of that organ and its apparent relation to that of the brain. He points out that Stahel recently showed that the superior thyroid artery bore in the degree of its development a constant relation to the "bulbus caroticus internus" (Krause), whereby the amount of blood transmitted through in the internal carotid in its winding course along an osseous channel could be regulated. Now the vertebral artery, in its course to the base of the brain, has a somewhat analogous disposition, both as regards tortuosity and relation to bone, as the carotid, and it is justifiable to infer that a similar relation to the above obtains between the inferior thyroid and the vertebral. This idea implies that the thyroid body can act as a sort of reservoir for blood, protecting the carotids and vertebrals from too great an influx. The great vascular supply of the thyroid is remarkable; in proportion to its size, it receives large arteries and has a plexus of veins which are in close connexion with the great venous trunks. The capillaries of the thyroid are also peculiarly disposed for the rapid removal of blood. Comparative anatomy lends support to the doctrine, the general fact being that in most mammals the brain is chiefly nourished by the internal carotid, and that in these animals both superior and inferior thyroid arteries arise from the common carotid trunk. Professor Waldeyer disputes the statement that the thyroid is exceptionally rich in lymphoid tissue, and refers its abundant nerve-supply to the large number of bloodvessels it contains.

THE STUDY AND TRAINING OF CHILDREN.

IT may appear to some superfluous that we should speak of the great importance of systematic training for young children. A matter of this kind must, we admit, be fairly understood by a great many responsible persons in the present age of the world's history. It is likewise very evident that, if we interfere too much with a process so natural as that of development, the artificial product will hardly realise all that we expect to find in adult manhood. We would strongly deprecate any interference which has this tendency. What is wanted is a plan or plans of school and household discipline which will be regulated, not merely by the maxims of past practice, but by an understanding of the signs of aptitude in children, and a knowledge of their physical, mental, and moral requirements, which cannot but vary with the advance of time and the growth of human experience. It has been sufficiently demonstrated, for example, that our ordinary methods of school education are not perfect, that the rapid cramming system is no more adapted to mind-culture than inordinate feeding accords with good digestion, and must therefore give place to a more deliberate process of instruction. Children must be studied as types and as individuals if we would train them and shape their future course aright. Such a study does not entail any elaborate investigation, and it is one which will repay parents and teachers by the success of its results when applied in practice. In this connexion we may draw attention to a series of six lectures, now being delivered by Dr. Francis Warner at the request of the Froebel Society, on "The Children: How to Study them."

THE PROPOSED NEW CHARTER OF THE ROYAL COLLEGE OF SURGEONS.

AT a meeting of the committee of the Association of Fellows of the Royal College of Surgeons of England held on April 23rd the following resolutions were passed and ordered to be sent to the Council of the College:—(1) "That the President and the Council of the Royal College of Surgeons be requested to convene a general meeting of Fellows and Members to consider and discuss the proposed draft Charter about to be presented to the Privy Council." (2) "That the Council of the College be requested to sanction the issue of copies of the proposed new Charter to those Fellows and Members who may apply for them." The committee also approved a letter to be sent to the Lord President of the Privy Council begging that the proposed Charter shall not be approved until the Association of Fellows has had an opportunity, by means of a deputation, of stating and explaining its defects.

FLOATING SPLEEN OR KIDNEY (?)

THE diagnostic difficulty that is sometimes encountered in respect to abdominal tumours in the left hypochondrium is well illustrated by an interesting case reported by Dr. Shattuck, of Boston. The case had been related by him in 1878 as one of "floating spleen." The patient was a young man of eighteen, who complained of severe pain in the above region after a sprain received in lifting a barrel, where examination detected a mobile tumour, which was agreed to be splenic rather than renal. Dr. Shattuck now (*Boston Med. and Surg. Journal*) comes forward to state that he was mistaken. Last year the patient was admitted into hospital with cancer of the skull, vertebral column, and ribs, leading to paraplegia from myelitis, and to cystitis and pyelonephritis. The abdominal tumour had remained unchanged. At the necropsy, besides the malignant disease, which also involved the liver and the left kidney, the spleen was found almost in its normal position, and was of usual size. The left kidney, however, was represented by a three-lobed mass of the size of two closed fists, and was provided with a mesonephron, which made it freely movable. It was in great part destroyed by malignant growth. It is an interesting point as to whether the fact of the organ being misplaced had anything to do with its becoming the seat of malignant disease. The patient had been liable to recurrent attacks of hæmaturia for five years before death, which may have been due to temporary strangulation of the ureter.

DRINKING-WATER AND DISEASE.

MR. WILLIAM P. MASON, of the Reusselaer Polytechnic Institute, Troy, N.Y., has contributed to the *Chemical News* an interesting observation on the production of disease by water polluted by normal sewage. About two months ago a family in Albany were, within a few hours, struck down with symptoms varying "from intense nausea to great, if not dangerous, prostration." It is unfortunate that the record of these symptoms is not a little more detailed. They lasted in the worst cases for over a month. On examination, it was found that the cistern which supplied the house had received most serious pollution from the private sewer of the house. When analysed, it was found to contain in grains per gallon—free ammonia, 1·05; albuminoid ammonia, 0·196; and chlorine, 3·22; with traces only of nitrates. Every single member of the household, which appears to have been a large one, and to have included several children who were on a short visit, was attacked, with the exception of one lady, the only person who had not drunk the water. Nothing apparently could be clearer than the evidence, which so far is very similar to much with which we are familiar. But now comes the real point of the story. "Up to the time of the outbreak none of the household had suffered from diarrhœa or kindred troubles, nor could I obtain any history of recent disease of any kind." Of course, as Mr. Mason points out, the sewage, although apparently not old, need not have been quite recent. It seems probable enough that sewage matters in a certain stage of putrescence, and swarming with bacteria, may become acutely poisonous, as meat is known to do under certain conditions. The general lesson is evident. We must not assume that a polluted water is safe because no pathological conditions can be proved to exist in the polluting matter.

THE TOXTETH PARK POISONING CASE.

THE adjourned inquiry into the above case was resumed on April 15th before Mr. Brighouse, county coroner. The deceased, Mary Jane Hamilton, aged eleven years, a child of weak intellect, "died somewhat suddenly after a violent illness." She had for several years been subject to fits. It was proved in evidence that her brother had brought home some sulphate of copper and sulphate of iron for the purpose of making experiments, and it was suggested that deceased had accidentally swallowed some of the mineral salts which had been dropped on the floor. The symptoms which for three or four days preceded death were mainly vomiting and retching, "stiffening of the hands" and "turning in of the feet." Dr. Shaw, who treated the deceased on one occasion during her last sufferings, made a partial post-mortem examination, and found what he believed to be a ragged perforation of the stomach, the result of the action of some irritant poison, and acting on this belief he gave a certificate, but declined to state the cause of death. Subsequently an official necropsy was performed by Dr. Rentoul, by order of the coroner. He discovered some green fluid in the abdominal cavity, and a perforation in the walls of the stomach, but whether this was caused by poison, or by the use of the knife at the former examination, he was not able to determine. The stomach and intestines were "more or less inflamed." From these reports it is absolutely impossible to draw a positive conclusion as to the nature of the perforation of the stomach. No mention is made, in the newspaper accounts of the case, of the facts by means of which one would endeavour to form a differential diagnosis between perforation (1) by incision, (2) by a corrosive agent, and (3) from post-mortem digestion. We lay no stress one way or the other on the absence of corrosion of the œsophagus, because if the sulphate of copper were swallowed in the solid form we should scarcely expect to find marked lesion of the gullet. A chemical analysis of the vomit, of the contents of the stomach, and of the fluid found in the abdominal cavity would certainly have given valuable information, and was indeed imperatively called for, but for some reason unknown to us no such analysis was performed. From the information before us, we can but consider the investigation was singularly faulty, and fully warranted the jury in returning an open verdict. Such a conclusion of the inquiry is to be regretted, especially as the means to render the latter complete were ready to hand. Unfortunately, too, there seems to have been a good deal of misunderstanding between the coroner, the medical men engaged in the case, and the police. Without going into these details, we may safely lay down one or two rules for the future guidance of practitioners called upon to investigate cases similar to that now under discussion. In the first place, we hold that whenever a medical man suspects that death is not due to natural causes, or even when he has no grounds for forming an opinion, he would act wisely in communicating with the coroner, and so shifting the responsibility upon the person the law designs should bear it. Further, a *partial* post-mortem examination is to be deprecated under any circumstances, and doubly so where the death is not

Digitized by Google

free from suspicion of "violence." Clearly, too, whenever a post-mortem examination is made by an independent person, the doctor who had charge of the patient should be informed of the fact, and given the opportunity of being present. The coroner for Central Middlesex invariably encloses with his order for the necropsy an intimation to this effect addressed to every medical man concerned in the inquiry.

THIRIAR ON VARICOCELE.

DR. THIRIAR of Brussels, in a clinical lecture on the Surgical Treatment of Varicocele, after mentioning that numerous methods of operation were in former times proposed and practised—such as castration, the section of the vas deferens, and the ligature of the arteries of the cord, which necessarily interfere with the functional activity of the testis,—spoke of the modern or therapeutic method as consisting essentially in the arrest of the circulation in the venous plexuses surrounding the vas deferens. Until quite recently, however, so many accidents—some of them fatal—followed operative procedures of this kind that many surgeons objected to resort to them for an affection which, however trying to the patient, cannot be considered as dangerous to life. Since the adoption of antiseptics the danger of these operations has been reduced almost to *nil*. The operation practised by Dr. Thiriar is the combination (proposed by Guyon) of Sir A. Cooper's plan of excising the skin with the old method of excising the varicose veins themselves; Heurteloup's plan of excising a flap of skin from the posterior surface of the scrotum he does not approve of, following Guyon and other surgeons in believing that the varicose condition is usually in the anterior plexus. His plan is as follows. An elliptical flap of skin is excised from the front of the scrotum and the bundle of veins dissected out and tied in two places, the intermediate portion being excised if the tumour is considerable. The dissecting out of the veins is a somewhat difficult matter, as there are several fibro-cellular layers to divide or tear through; the artery has to be carefully separated from the veins, a proceeding which up to the present time Dr. Thiriar has not found attended with difficulty. The wound is washed with a corrosive sublimate solution, and the lips united by a continuous suture, which is the form Dr. Thiriar prefers as a rule; antiseptic dressings and compress bandages are applied, and in a few days the patient is discharged permanently cured.

DISPOSAL OF REFUSE.

"Dust and Ashes: How to Deal with them," was the subject of an interesting lecture given last week by Mr. Alfred Fryer at the Parkes Museum of Hygiene, in which the lecturer discussed the most economical and effectual way of getting rid of the contents of ashpits. His argument that the use of fire for this purpose was an absolute necessity was well supported by those who took part in the discussion, and he adduced considerable evidence to show that this method could be adopted in large centres of population, quoting among other places Whitechapel, where there is a destructor which belongs to the vestry of that district, and Lett's Wharf, near Waterloo-bridge, where the Corporation of the City of London have erected a similar furnace. He referred to the alarm which had been created by a recent proposal to construct a furnace at Kensington, and to the unfortunate decision of the House of Commons in rejecting the Kensington Bill on its third reading—a Bill which, by the way, we recently inadvertently stated had passed this stage. This decision is the more to be regretted seeing that Londoners have now ample opportunity for correcting any erroneous impressions as to the amount of nuisance which the destructor creates, but evidently the work of education must progress further before the method of destruction by fire is generally accepted. The Council of the Parkes Museum have therefore done well in inviting Mr. Fryer to relate his own experience of the working of the destructor in other towns where it has been in use for many years.

THE PURIFICATION OF WATER.

IT has long been known that water may be clarified by the formation in it of a precipitate which, as it falls, will carry down mechanically the lighter, and of course the more dangerous, portion of the suspended matters, which otherwise are very slow in separating. In Clark's well-known process for softening water a sufficient quantity of lime to combine with the free carbonic acid is mixed with the water. The precipitate of carbonate of lime—if we may still use the familiar old name for the calcium carbonate of modern chemists—carries down with it all suspended matters, including bacteria, and the water remains not only softer but very much purer. Carbonate of soda is an even more powerful precipitant, as it removes permanent as well as temporary hardness. In either case the deposition is, however, somewhat slow, and to avoid the use of depositing tanks a filter press was used in the Porter-Clark process, which was shown in action at the Health Exhibition. An American contemporary, the *Boston Medical and Surgical Journal*, reports that Prof. Dobroslavine of St. Petersburg advises as a good precipitating agent a solution of perchloride of iron followed by a solution of carbonate of soda. Simple and devoid of inherent novelty as the suggestion is, it is very sensible. Translated into English weights and measures, the quantities used are about three grains of perchloride of iron and four grains of soda crystals per gallon of water. The precipitate is said to settle in about forty-five minutes and to leave the water perfectly clear. The quantity of carbonate of soda is not sufficient for the complete decomposition of the iron salt, but would convert it into a heavy, insoluble, basic chloride, which would doubtless settle easily. So simple an experiment is well worth trying. It is noteworthy that by slightly increasing the quantity of carbonate of soda the water could be softened. We have often wondered that the softening of water for domestic uses is not more frequently practised in private houses. The addition of a very small quantity of carbonate of soda to the water in a cistern will remove even excessive hardness in a few hours at an almost inappreciable cost. If the cisterns are used in pairs the white deposit from one may from time to time be removed by flushing with water while the other is in use. The troublesome furring of boilers and hot-water apparatus might in this way be avoided.

THE JUGULAR HUM.

THE unreliability of the well-known "bruit de diable," or jugular hum, as a sign of anæmia, which was pointed out by Weil, whose objections have been disputed by Guttmann, has been again proved by Dr. Reinhold Apetz (Virchow's *Archiv*, Bd. 107, Hft. 3) upon the results of the auscultation of 660 individuals, of whom 115 were anæmic, 161 "barely" anæmic, and 384 "not anæmic." The murmur was detected in the proportion of 51 per cent. of the first class, 46 per cent. of the second, and 39 per cent. of the third. Without following the writer through his analysis, which corresponds fairly closely with the similar observations of Weil, it may be interesting to cite the conclusions at which he arrives. These are to the effect—1st. That venous murmurs detected in the internal jugular vein under all circumstances depend in the first place upon the age of the affected individual, the murmurs becoming less frequent with advancing age. 2nd. That venous murmurs detected by turning the head to the other side are of no value in the diagnosis of anæmia, but have

Digitized by Google

only a physiological importance. 3rd. That some pathological importance specially belongs to the true murmurs detectable when the head is kept straight in the upright position, when they occur loud and continuous in individuals at middle age (twenty to sixty years); yet they are generally too insignificant to be of value in the diagnosis of anæmia. 4th. Under no conditions does the venous murmur have any special diagnostic value for chlorosis and other anæmic states.

STOPPAGE OF WATER-SUPPLY FOR NON-PAYMENT.

THERE can be no question as to the serious inconvenience occasioned in a household by the stoppage of its water-supply. A frequent result of continued cold weather, and an occasional but not infrequent consequence of non-payment of dues, it is at any time a source of much annoyance, and, what is more important, of a train of diseases which are bred and fostered by uncleanliness. We need not dwell on the connexion between sewer air and infectious fevers, on the absolute necessity of water, under our present system, for the removal of excreta, and for flushing freely and fully all waste-pipes, on its utility for cooking purposes, and its natural place as a beverage. All these are matters of common information. It is well to note, however, that the consequences of a want of water are not necessarily limited to the house which is primarily affected by it. If, for example, the sewage arrangements of that house be thrown out of working order, those of neighbouring buildings are not unlikely to become indirectly involved. Thus, one focus of disease readily becomes a parent of others. It is with a view to the prevention of such risks as these that certain members of the House of Commons have brought forward a proposal that water companies should be restrained in future from cutting off the water-supply of any house in default of payment of the water-rate, and should be allowed as compensation a preferential claim on the revenue derivable from the said house. The plan, as drafted on paper, seems as if it would work well, though perhaps it might be objected on behalf of the companies that it does not cover a number of cases where houses are let to a very poor class of tenants, whose payment of rent or of any dues whatever is a very precarious possibility. It may well be doubted, however, if their present power of stopping the supply is of much use to the companies in such cases. In so far as it is wont to be applied, the local authorities might perhaps be induced to meet them in the public interest on the question of payment, in order to prevent its application. At all events, the proposal to which we have referred is one worthy of consideration, and if it can be effectively carried out will do something to limit the spread of disease.

ARTIFICIAL AND HYPER-ALIMENTATION IN PHTHISIS.

IN an account of the effects of artificial and hyper-alimentation, as practised in Professor Pel's wards in Amsterdam, Dr. van Eeden states that the meat powder treatment introduced by Débove (which he had had an opportunity of studying in Paris) is always of service in phthisis when the disease is not very far advanced, and when it is not of a "malignant" nature. The cases which do best under this treatment are those in which there is no hereditary taint and where the disease has progressed regularly, with a not very rapid loss of strength, and with only slight hectic, anorexia, anæmia, and emaciation. The chances of successful treatment are slight where the disease has made rapid progress, with a continuous high temperature. The existence of a considerable degree of pyrexia is, however, no contra-indication to the use of the treatment. If diarrhœa and gastric irritation are produced by the artificial alimentation, it is best to discontinue it. In order to accustom the stomach to the meat powder, small quantities only should be given at first—not more than about half a pound during the twenty-four hours; this amount may gradually be increased to one pound and a half. The use of the œsophageal sound for the introduction of the food is considered by Dr. van Eeden as advisable in all cases, and imperatively necessary in hyper-alimentation. Quantities exceeding three pounds of meat powder per diem, however, are not by any means always required, and should only be given when smaller amounts do not succeed, and where the patient bears the treatment well. The method must be diligently and patiently practised, and the weight of the patient accurately noted. Dr. van Eeden remarks that so little is known of the way in which hyper-alimentation controls the development of tubercle, that whoever attempts to practise Débove's treatment must be prepared to meet with many difficulties and disappointments. Notwithstanding this, however, he has witnessed some surprisingly good results from its employment.

EXPLOSIVE SODA-WATER BOTTLES.

THE yearly increasing consumption of temperance drinks, particularly of aerated waters, is on the whole a matter for congratulation. It is also a fact which renders the more necessary some precaution lest the greater demand should itself entail certain public disadvantages which might with some forethought be avoided. With regard to cost, for instance, recent experience has shown that there is in many quarters a tendency to unjustifiable extortion in the retail sale of these very simple drinks. A warning of a different kind has lately been communicated through the daily press with reference to the imperfect filling of soda-water bottles. A fault of this description is little, if at all, less blameworthy than that to which we have already referred. It is necessary for the safe use of aerated waters that the water itself should be in a due proportion to the gas which it is intended to absorb. If it is not, the excess of gas may cause, and repeatedly has caused, an explosion, sometimes with serious consequences. How far in such cases of accident the result was due to some flaw in the bottles themselves is doubtful. The one apparent fact is an excess of the charge of gas. It is easy to understand how in a warm atmosphere this would suffice to cause an explosion, and it is as necessary as it would be profitable to makers that sufficient care should be taken in the preparation of these beverages to minimise the chances of accident in the future.

THE DUSTMAN AND THE WIND.

DURING the late high winds and the general dryness of everything, many Londoners must have suffered from that absurd and dangerous pest of the metropolis, the present system of dust removal. Turning a corner the other day, in the teeth of a strong east wind, we were confronted suddenly with the grim apparition—cart, ladder, basket, and all. Flight was impossible. We had barely time to shut our eyes and mouth when what appeared to be about half the savoury contents of the basket deluged us. The cart was already over-full, and in another moment a foul simoom of dirt was careering down the street. Could anything be more disgusting or more dangerous? Who can tell that infectious disease was not present in the very house from which the last basket was carried? Why do Londoners tolerate the nuisance? There are many known ways of disposing of house refuse; but we are convinced that the very worst, the most stupid and dangerous, is that which seems to be immortal in London—the open cart and the rotten basket.

DR. BALFOUR, F.R.S., HONORARY PHYSICIAN TO THE QUEEN.

WE were extremely gratified at a late announcement in the *Gazette* to the effect that Surgeon-General Balfour, M.D., F.R.S., late of the Army Medical Department, had been appointed one of the Honorary Physicians to Her Majesty. Dr. Balfour is a man of deservedly high scientific reputation; he is, in addition to this, a Fellow of the Royal Society, and a Vice-President of the Statistical Society of London. He was Secretary to Lord Herbert's Commission after the Crimean War, and did excellent and original work as head of the Statistical Branch of the War Office; in fact, he organised that branch, and laid down the lines of our military statistics on a better basis even than they are at present. Dr. Balfour has the reputation of having been an excellent administrator, and, as principal medical officer at Netley and Gibraltar, he was most popular and successful.

GASEOUS RECTAL MEDICATION.

THE remarks on gaseous rectal injections by Dr. Burney Yeo which appeared in THE LANCET on the 16th inst. will serve to give more prominence and emphasis to a method of treatment which may have "something in it," but which cannot be said to have yet had a fair trial at the hands of English practitioners. At the same time, it is hardly correct to say that the method has been met with derision, if not contempt, for it has been systematically, though not extensively, practised by Dr. Heron at the Victoria Park Chest Hospital, and it is now some time since Sir Andrew Clark invited a number of medical *confrères* to a demonstration of the apparatus employed in the method by M. Bardet. Further, American physicians appear to have taken it up, and apparently with considerable success. With Dr. Burney Yeo, who appears to us in this matter to adopt the attitude most in accord with true therapeutic science, we do not think it necessary to suppose that the sulphuretted or other gas must act after the fashion of a true germicide or antiseptic; using the latter term in its widest sense, as Dr. Yeo would probably employ it. If we admit that the methods of rectal gaseous medication are antiseptic in their action, it does not necessarily follow that the antiseptic agent acts in a germicidal fashion on the causes of septicity, or that the gas neutralises the effects or products of the action of the germs; for it may be that the value of the treatment, supposing it to have any, consists in improving the nutritive powers of the tissues, in increasing their vitality, thereby rendering them more able to cope with deleterious influences, or with the germs, by affording an unsuitable soil for the activity of the latter. It is not, however, with the mode of action and scientific *rationale* of gaseous rectal medication that we are now principally concerned; what we would urge is a more extended trial of the method for which so much has been claimed in France and America. Already the evidence is forthcoming that the treatment has been followed by many signs of improvement, in at least some of the patients, and perhaps chiefly in those whose affections are not of an altogether irremediable nature, such as local affections of the pulmonary tissues and various forms of chronic bronchitis; whilst the rapid forms of phthisis and other acute febrile pulmonary processes do not seem to be benefited by this treatment, which, though it may be tolerated by the system, is certainly not always borne with equanimity by the patient. It is clear that the day has not yet arrived when rapid phthisical processes may be surely arrested by therapeutic and hygienic art. This much must be said, because a notion has been getting abroad through statements circulated in the lay press that rectal injections are certainly curative of consumption. It does not seem to be sufficiently appreciated by the public that cases of genuine consumption are being, have been, and doubtless will be cured by the resources already at the command of the profession. To say that all consumption is curable is to make as untrue a statement as to say that all consumption is incurable. Some cases are amenable to treatment; the bulk, perhaps, are not. To be able to say that the universal affirmative proposition is true is a consummation devoutly to be wished, and it is in this spirit of hope that we would recommend a fair trial of the new method of treatment, the details of which are carefully described by Dr. Yeo in the lecture to which we have referred.

ATTENDANCE BY UNQUALIFIED ASSISTANTS AT CHEAP DISPENSARIES.

A BAD case in point is reported in the *Newcastle Daily Chronicle*—that of John Potter, aged thirty-one, who suffered from pain in his side and a severe cough. The father of the patient sent for "Dr. Hardy of Shields-street, Shieldfield." The person who attended was not Mr. Hardy, but his unqualified assistant, who told the father that his son's heart was much affected. Dr. Arnison was called in the day before death, and pronounced the case one of double pneumonia. When the patient died they went to Mr. Hardy's for a certificate. He had never seen the case, but filled up a certificate, saying that he had attended the case and seen it on April 20th, and that the cause of death, to the best of his belief, was acute nephritis. The coroner reflected severely on Mr. Hardy's action in certifying in a case which he had not seen, and in which the diagnosis of his unqualified assistant seemed to have been as much at variance with the fact as the statements in the certificate. The coroner intimated that he would refer the facts to the Registrar-General. He very properly said that the rectification of such irregularities should not rest with the medical profession. It concerns the public and the Registrar-General. We hope the Registrar-General will investigate the facts, and, if necessary, refer them to the Medical Council.

MOORISH PRISONS.

AN agitation has been raised, chiefly through the instrumentality of Mr. Jose Perdicaris, a wealthy and philanthropic American gentleman residing at Tangier, concerning the brutal treatment of Moors imprisoned for debt. Financial, and to some slight extent political, questions are involved in this movement, and with these, of course, we are not concerned; but we are free and anxious to join in the general protest made against the barbarity prevailing in Moorish prisons. The new consul representing the United States of America recently fitted out an expedition which went to the towns of Alkazar and Laraiche to release seventeen individuals imprisoned on so-called American claims, and they found that no less than three out of this number had died in prison. A correspondent, who has had opportunities of visiting each of these prisons, testifies that the only wonder is that such pest-houses do not prove even more fatal. The stench arising from the want of closet accommodation is simply appalling. Overcrowding is constantly allowed, and when fever breaks out, no precaution whatever is taken to prevent the disease spreading. The prisoners for the most part are covered only by a few dirty and torn rags swarming with vermin. They are also generally put in irons, and no food is provided. The prisoners are allowed, but not compelled, to work at making cords and fancy baskets, which they try to sell, to enable them to buy bread. But this resource is so slender that, unless the prisoner has food brought to him by his friends or relatives outside, he runs every risk of dying of starvation. Several cases of this kind are known to have occurred, and the prisoners were not criminals, but untried

Digitized by Google

debtors. Now, so far as American *protégés* are concerned, the movement, successfully conducted by Mr. Perdicaris, assisted by Captain Rolleston, has resulted in the liberation of the prisoners and the abolition of protection. Henceforth men will no longer be incarcerated at the bidding of an American *protégé* who avails himself of his privileged position to refuse his debtor the right of trial. The trade of the usurer will thus become more difficult. But, while applauding the abolition of such abuses, we venture to go a step further. We make bold to claim, even for the hardened criminal, a more humane treatment. There are thirteen foreign legations at Tangier. The Sultan of Morocco knows that he has no army, no material means of resisting the demands of any civilised power. If he has held his own so long, it is not his own strength but the jealousies of the rival powers which have saved Morocco from sharing the fate of Algeria or of Tunis. Nevertheless, these various diplomatic agents might agree to unanimously demand reforms in the condition of the Moorish prisons. This is no political question; it does not affect the delimitation of the frontiers. The rights advocated are the abstract rights of humanity to humane treatment, combined with the necessity of preserving the public health. Moorish gaols are centres of epidemic disease; they are a standing menace, not only to the lives of the prisoners, but to the health of the free men who live without their walls. These latter comprise, in such a town as Tangier, a considerable number of Europeans. Tangier also is becoming yearly a more popular health resort, therefore the foreign diplomatic corps could easily find good reasons to interfere on behalf of the Moorish prisoners and obtain some sanitary improvements in the condition and management of the gaols.

SUDAMINA IN TYPHOID.

THE occurrence of sudamina is fairly common in typhoid fever. Murchison observed them in about one-third of his cases, but attributed no special significance to them. M. Baradat de Lacaze (*Rev. de Méd.*, April, 1887) discusses the subject in some detail, especially from the point of view of prognosis. He concludes that the appearance of such eruptions (sudamina or miliaria) after the third week in a severe case is of favourable omen, and that within a day or two the temperature will fall. But the same meaning does not attach to the like eruptions that appear in some cases before this time—e.g., in the second week. Prognosis in typhoid fever is admittedly very uncertain, and any sound facts to guide in forming it must be received with attention. In addition to these critical eruptions connected with the sweat glands, the writer cites M. Chauffard's opinion that the occurrence of multiple abscesses and of polyuria is also an indication of a favourable termination of the disease.

CONSUMPTION IN AUSTRALIA.

A CORRESPONDENT writes to us from Sydney (New South Wales):—"The propriety of sending consumptive patients to the Australian colonies is a question which the medical profession in England must necessarily take great interest in. I therefore venture to enclose an article from the Melbourne *Age* of March 3rd bearing upon the subject. I am not a medical man, but from my experience of the climate here and in Victoria, especially near the coast, I should say there is not a more treacherous country in the world. It is most common for the thermometer to show variations in the temperature within a couple of hours of from 40° to 50°." The article from the *Age* deals with the proposed consumption hospital for Melbourne, and points out the urgent need for it, owing to the rapid increase of the disease in the colony of Victoria. The above facts are already well known to us. Consumption is common in Australia, and is increasing with rapid strides. The idea that the Australian climate is in general either a sure prophylactic or a certain cure for the disease is a common but baseless error. It is, in point of fact, an unpardonable looseness of speech to deal with the climate of Australia as a definite and invariable entity. There are many climates in Australia—coast, mountain, plain, and desert; and some of them, especially the coast climate—to which, unhappily, for obvious reasons the consumptive too commonly resorts,—are most injurious in chest affections. On the other hand, the reputation won by Australia in the treatment of consumption is not a myth or a mistake. Many parts of the interior have an admirable climate—dry, bright, sunny, exhilarating, and fairly equable; the chief drawback being the hot summer. The other seasons are delightful, and the consumptive who goes inland to one of the sheep "stations," and lives the primitive out-door life which there prevails, stands a good chance of recovery, or at least of a great prolongation of life.

TONSILLITIS AND DIPHTHERIA.

IN a paper on Follicular Amygdalitis (*Medical Record*, Nov. 1886) Dr. A. Jacobi points out that this term is misleading, inasmuch as it covers a variety of conditions—catarrhal, purulent, fibrinous, and diphtheritic; and that the last-named form especially is liable to be mistaken for the other non-contagious varieties. The catarrhal and the diphtheritic are the most frequent. Acute catarrh of the tonsil is not unilateral when produced by cold, and is accompanied by the universal hyperæmia of the larynx. "Whenever there is an acute attack of *unilateral amygdalitis*, the latter *is the result of either trauma or infection*," is the dictum which he proffers. The distinction between the catarrhal and diphtheritic forms of follicular tonsillitis rest mainly in the character of the membranous deposit in the latter form, the small patches of whitish or whitish-grey colour being very adherent, and sometimes becoming confluent. Albuminuria is not necessarily present in the diphtheritic form, and it occurs in the catarrhal when there is high fever. Nor is fever a necessary concomitant of the infectious variety; its occurrence depends rather upon the extension of the morbid process to deeper parts. The whole tenor of Dr. Jacobi's paper is to deny the assertion of Fraenkel that "angina lacunaris" is a perfectly distinct disease from diphtheria, but that many cases of the former are examples of mild diphtheria, capable of transmitting the disease by infection, and therefore to be guarded with as rigid precautions as the well-marked cases of diphtheritic infection.

SANITARY PROGRESS AT LEEK.

IN his last annual report on the sanitary condition of the town of Leek in Staffordshire, Mr. J. J. Ritchie, the medical officer of health, draws attention to some interesting points in connexion with the results of the sanitary progress which has been made. Thus, the statistics compiled show that for the years 1881 to 1885 the mean expectation of after-life from birth of persons in Leek was twenty-two years more than would have been the case had things remained as they were during 1851-60, before any attempt was made to grapple with the unhealthy conditions of the town. Mr. Chadwick, C.B., having made inquiry as to what was the money value to the community during the twenty-five years 1861-85 of the important increase in longevity and freedom from sickness which had been brought about, the following particulars showing the saving effected were collected for him: Maintenance of sick (including medical and other attendance at 5*s.* per week) amounted to £35,560; money saved on productive labour (10*s.* per week for males and 5*s.* per week for females), £25,784; money saved on cost of funerals, at £5 each, £10,320; total money saved, £89,464, which sum is equal to a direct saving of

Digitized by Google

£3586 per year. It was further shown that during the same period the deposits in the Savings Bank had increased twentyfold, and the capital of the Friendly Societies threefold; that the receipts in the Leek and Moorland Building Society had risen from £8421 in 1861 to £54,858 in 1885, and those of the Leek United Building Society from £905 in 1863 to £29,898 in 1885; and these sums, it is believed, have been materially influenced by the state of things above referred to. Incidentally, it may be added that the freedom of the town from fatal infectious diseases has been largely brought about by the almost immediate isolation which is secured in the sanitary hospital which has been provided and has been long in use.

MICROBES AND SUPPURATION.

A. ZUCKERMANN (*Centralbl. f. Bacteriologie u. Parasitenkunde*, No. 17) relates his experiments upon suppuration, which have led him to these conclusions: That no chemical, mechanical, or thermic influences can excite suppuration if they are wholly free from microbes; and in cases where these causes apparently act it is probably through some pyogenic microbe. For substances chemically pure may be mycotically impure; thus some disinfectants are not always free from microbes. The varieties of microbe known to cause suppuration are staphylococcus pyogenes aureus, albus, and citreus; streptococcus pyogenes; and in fætid abscesses, bacillus pyogenes fœtidus. Inoculations with staphylococcus and streptococcus produce fatal results if injected in large amount into animals, or lead to suppuration if death do not occur. The pyogenic microbes must have a very general distribution in nature; they may enter the body through the air-passages, the intestinal canal, and especially the skin, and by means of small wounds or the orifices of the cutaneous glands. Staphylococcus is more frequent than the streptococcus pyogenes.

VACCINATION OFFICERS' ASSOCIATION.

WE note with pleasure the continued development of the Association of Vaccination Officers, which has just published its third annual report. Subjects of much interest have been discussed during the year, and a paper by Dr. Cory has been issued. There are probably no officers who can derive more benefit from combination than those engaged in the enforcement of the Vaccination Acts. Their duties are of a nature to require considerable information, and every officer must frequently feel the necessity for consultation with his fellows. Ample opportunity for this purpose is given by the Society, and it would be well if the fullest advantage were taken of it by all. The work of the vaccination officer is of great importance to the public, and everything which tends to create efficiency in its performance deserves sympathy and encouragement.

THE SHARP SPOON IN ABORTION.

DR. A. R. FISHER, assistant in Professor Slavianski's clinic in St. Petersburg, relates, in the March number of the *Russian Obstetrical and Gynæcological Journal*, his experience of an operative procedure recommended by Boeters, Mundé, and Fehling in cases of abortion, where the embryo is not expelled naturally. The patient is placed on the back, the knees being separated by assistants. Anæsthesia is not required. The vagina is well washed out with a disinfecting solution, and then the cavity of the uterus is similarly irrigated by means of a double-current catheter, which is passed after the cervix has been drawn down with forceps. A sharp spoon is then introduced into the os uteri, which it is not necessary to dilate with tents, and the cervical canal scraped out, after which the instrument is made to sweep round the entire cavity of the uterus, scraping off the deciduous mucous membrane close to the muscular layer. When this is reached a peculiar grating feeling is experienced, which is very characteristic, and which serves to denote that the scraping has been carried far enough. If the contents of the uterus are considerable in quantity, the operation is broken off two or three times for disinfectant irrigations through the double-current catheter. At all events, the uterus is well washed out with an antiseptic liquid at the conclusion of the operation. An iodoformized plug is then inserted into the vagina, and a good dose of ergot given. The results of this operation are stated to have been most satisfactory, but the author does not recommend it in cases which have been left too long to themselves, where more or less putrefaction must have taken place. Nine cases are reported, in only one of which was any unfavourable complication observed; this was a slight amount of parametritic effusion, and it was not certain that it was due to the operation.

THE CABINET AND THE PROFESSION.

As it is probable that the action of the Ministry may be required to be influenced by the profession in the matter of some impending legal questions of great importance to medical men, it may be worth while mentioning that three members of the Cabinet are connected through their ancestors with the profession. Lord Cadogan is descended from Sir Hans Sloane, the celebrated physician. The estate the family holds in Chelsea was the produce of the fortune Sir Hans made as a physician. Both Sir Henry Holland's father and grandfather were well-known medical practitioners. Mr. Matthews, the Home Secretary, is descended from a physician both on his father's and mother's side. Dr. Munk in the Roll of the College of Physicians, vol. ii., says—"John Matthews was born in Herefordshire; was M.D. at Oxford in 1782, Fellow of the College of Physicians in 1783, physician to St. George's Hospital in 1781; resigned that office in 1783, when he relinquished the practice of his profession, became colonel of the Herefordshire militia, and died at his seat, Belmont, in that county, in 1826." The Home Secretary's father (the author of a well-known work, "The Diary of an Invalid") married a daughter of Dr. Blount, who practised as a physician for some time in Hereford.

LIGATURE OF THE FEMORAL IN POPLITEAL ANEURYSM.

IN an article on "Popliteal Aneurysm" by Don José A. Esteves, published in the *Revista Argentina de Ciencias Médicas*, it is stated that Dr. Pirovano employs in the Buenos Ayres Clinical Hospital in these cases the ligature of the femoral artery, intermittent compression being practised by means of Broca's compressor for some time previously for the purpose of developing the collateral circulation. The operation itself is carried out with antiseptic precautions and local anæsthesia. Twenty cases, some of them of aneurysms of very considerable dimensions, have been thus treated, with entirely satisfactory results in every instance.

A "JUBILEE" COOKERY BOOK.

THE fiftieth year of Her Majesty's reign is likely to be remembered in time to come, not only because of the interest proper to it, but perhaps equally as having been the parent of innumerable undertakings and productions, great and small, which inherit from it a nominal dignity. Of these, one of the latest and smallest, though, perhaps, not the least useful, is a "Jubilee Penny Cookery-book." This little book, by the authoress of "Cookery for our Sick and Invalid Poor," aims at introducing among the many to whom the cost of food is a serious consideration ready methods of cooking, with hints as to the choice of materials, which, if rightly applied, should furnish a diet as varied

Digitized by Google

and palatable as it is simple and inexpensive. We cannot altogether agree with an introductory statement in it, which deals with the relative nutritive value of certain kinds of food: where, for example, herrings are preferred to beef and mutton; and a shilling's worth of cheese, without regard to its digestibility, is said to have more "stay" in it than the same money value of meat. The numerous convenient recipes here collected are not, however, affected by the imperfections of the prefatory notice, and form together a body of information which must be useful to the frugal housekeeper.

A PRACTICAL COURSE OF BACTERIOLOGY IN LONDON.

A COURSE of instruction in Bacteriology will be given this summer at King's College. The object of the class, as set forth in the syllabus, is to afford an opportunity for gaining a practical knowledge of the more important species of micro-organisms, and to give instruction in the methods of cultivation as well as the special histological methods employed for detecting bacteria in the tissues. The work each day will be preceded by a short lecture illustrated with diagrams and typical microscopical preparations. The class will meet on May 16th, and will be taken by Mr. Crookshank, who has just returned from visiting the laboratories at Turin, Rome, and Berlin. This course will supply a felt want, and no doubt medical officers of health and many senior students and practitioners who have been unable to study in the laboratories abroad will avail themselves of this opportunity for learning the new biological methods, and for gaining access to cultivations of micro-organisms and the necessary material and apparatus for following this interesting and valuable line of research.

THE RED CROSS IN ITALY.

THE recent military events in Africa have given a much-needed stimulus to this society for the relief of the sick and wounded in war. Several communes throughout the peninsula which had previously failed to contribute to it have now come forward handsomely, if tardily—Rome subscribing towards it 5000 francs (£200); Milan founding a fund for an annual donation to it of 500 francs (£20); Turin, through one of her societies, giving 1000 francs (£40); and other cities and towns, mainly in Upper Italy, subscribing according to their ability. The Central Committee of the Italian Red Cross, thus reinforced as to means, has lost no time in sending to the front supplies of medicines and comforts, so that the military hospitals in the garrisons westward of Massowah are now much better off as regards these requisites than, to the discredit of the Government, they have yet been since the beginning of the campaign.

"ADDED WATER" IN MILK.

A CASE curiously illustrative of some remarks we made in a recent article is reported. A county analyst reported that a certain sample of "babies'" milk—that is, milk from a single cow—contained 10 per cent. of added water. He was afterwards requested to witness the milking of the cow, and to draw a sample for himself. The second sample, when analysed, was found to contain more "added water" than the first, and was, the analyst believes, the worst sample of genuine milk on record. What, then, is to be done? Is the already low limit of purity to be made still lower, or is the public analyst to continue to report the presence of added water when he knows that possibly no water has been added? Either alternative is undesirable, but perhaps in the public interest the second is the least so. The case, however, confirms our previous opinion, that the difficulty can only be avoided by an alteration of the law. In the next Adulteration Act let the law do for milk and some other articles what it has already done for spirits—viz., provide a definition, and fix a limit below which the vendor must not pass. The limits upon which public analysts, including the chemists of Somerset House, base their calculations are necessarily founded on very poor samples, and in a new Act it is possible that they might be slightly raised without injury to honest traders and with manifest advantage to the public. But even such low limits as 8·5 per cent. solids not fat, 2·5 per cent. fat, and 0·7 per cent. ash, would ensure the public a trustworthy, if not a rich, milk, and would remove all ambiguity from the interpretation of the law. Some important drugs might, and in our opinion certainly should, be treated in a similar manner.

INTER-COLONIAL MEDICAL CONGRESS.

IN accordance with the circular issued last year by the Provisional Committee, to which we drew attention at the time of its publication, a general meeting of subscribers to the fund of this congress, which is to be held at Adelaide, has taken place. Dr. Verco was chosen president, and an influential executive committee was appointed. The governors of seven colonies have expressed their approval of the project, and intimated their wish to become patrons of the meeting. The congress will, as is usual, be carried on in sections, thirteen of which have been defined. The days of meeting will extend from August 30th to September 2nd, both dates included; and, notwithstanding the great distances to be traversed by the majority of intending visitors, and the existence in the same month of a counter attraction in the United States, it is hoped by its promoters—and, so far as we can judge from the reports we have received, justly so—that the federal nature of the gathering and the opportunities it affords for the discussion of subjects common to the interests of practitioners throughout Australasia will combine to secure a large and representative attendance.

THE AFFILIATION OF HOSPITALS AND DISPENSARIES.

THE following resolutions were passed by the committee for organising medical attendance on the working classes at its meeting on Tuesday: "That in the opinion of this committee the out-patient department of hospitals should be brought into consultative relation with the provident dispensaries and medical men of their respective neighbourhoods, and that the governing bodies of hospitals should grant priority to all out-patients who bring recommendations from provident dispensaries or medical men." Sir Spencer Wells presided. The subject of the affiliation of hospitals and dispensaries will be continued at the next meeting, on Tuesday, May 10th.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Carl E. Miriam, formerly Professor of Physiology at Kieff, at the age of seventy-five.—Dr. Nathaniel Lieberkühn, Medical Privy Councillor and Professor of Anatomy in Marburg University, at the age of sixty-five. The deceased professor was the son of the discoverer of Lieberkühn's follicles, and was a disciple of Johannes Müller, and a fellow-student of Dubois Reymond, Helmholtz, Ludwig, and Virchow. His own researches, which were numerous, were mainly connected with development. He was formerly Prosector of Anatomy in Berlin.—Dr. Joao Silva, Professor of Pathology in Rio de Janeiro, and chief of the Faculty of Medicine in that University.

SANITARY DEMONSTRATIONS TO MEDICAL MEN.

WE would call the attention of medical practitioners to a series of sanitary demonstrations which have been organised at the Parkes Museum at 5 P.M. on three consecutive Mondays next month, and to which admission is free to all members of the profession. The first demonstration will take place on Monday, May 9th, and will be conducted by Professor Corfield, M.D.; on Monday, May 16th, Mr. Rogers Field, M.Inst.C.E., will give a demonstration; and the last demonstration will be held by Mr. P. Gordon Smith, F.R.I.B.A., of the Local Government Board. In this way the medical, engineering, and architectural aspects of the question of the sanitary arrangements of dwellings will be successively brought under notice; and we expect that the number of medical men who are interested in the subject is such that the Museum authorities will find that the arrangements they have made will secure appreciative attendances.

THE DUKE OF WESTMINSTER ON THE JUBILEE.

THE Duke of Westminster in a letter to *The Times*, says the hospitals of London in this Jubilee Year should certainly not be neglected; our own view is that they should be the chief objects of favour. It seems to be very much feared that many of the ordinary charities will suffer from the Jubilee movement tending to divert funds. Surely no one will do the Jubilee such dishonour as to withdraw any established subscription from a worthy cause! The best way of celebrating it will be to make additions to ordinary subscriptions, especially in favour of the general hospitals.

MEDICAL PRACTITIONERS AND DENTISTS.

A QUESTION is raised by a correspondent of the *Journal of the British Dental Association* as to the propriety or taste of medical practitioners charging full fees where they are asked to attend dentists. Our opinion is strong that medical men who owe so much to dentists will find it highly agreeable to be of any service in return. Who that has had a tooth saved, or even a tooth skilfully extracted, and who knows the extent to which dentists are consulted by medical men and their families, and the unfailing kindness which is experienced in this way at their hands, will have a doubt that in treating dentists as we should treat medical men we are acting on the best instincts of human nature, as well as on the best traditions of the profession? We have, however, always maintained that dentists should hold a surgical as well as a dental qualification, in which case the question need not have been raised.

LONG PEPPER AS AN ADULTERANT.

THE magistrates of Lancaster have properly decided that what is known as long pepper is not what the public understand by the word pepper, and that as it is cheaper than the cheapest pepper, and is, moreover, coarse and disagreeable in smell, its admixture with genuine pepper is an adulteration. It was stated by Dr. Campbell Brown that long pepper, an article of very small commercial importance, was the fruit of a plant which grows wild in the water courses of India, whereas true pepper comes from a perfectly different plant, which is carefully cultivated. Long pepper is chiefly used for pickling purposes.

THE COCCUS OF GRANULAR LIDS.

DR. E. SCHMIDT is stated to have succeeded in finding the micro-organism described by Sattler in granular lids (trachoma), which, he says, is very similar to staphylococcus pyogenes. By cultivating this coccus he succeeded in inducing granular lids in dogs and cats.

THE ANATOMICAL SOCIETY.

THE foundation meeting of the Anatomical Society will be held on Friday, May 6th, at 5 P.M., at the Medical Society's rooms, 11, Chandos-street, Professor Humphry in the chair. All those interested in the movement are invited to attend.

FOREIGN UNIVERSITY INTELLIGENCE.

Florence.—A bronze statue to the great Italian medical jurist, Francesco Puccinotti, has just been unveiled.

Halle.—Professor Kaltenbach, of Giessen, has been offered the vacant chair of Midwifery.

Kazan.—Up till recently Dr. Skalosuboff, the professor of nervous diseases, has been obliged to confine his demonstrations to such patients as could attend at the out-patient department, having no beds assigned to diseases of this nature. Now, however, a small clinical establishment has been allotted to his chair, so that students will enjoy more extended opportunities of study.

Königsberg.—Dr. Carl Brandt, *privat docent*, has been appointed by the Minister of Education to carry on the duties of the vacant chair of Zoology up to the end of the next winter session. Dr. Brandt was formerly assistant in the Zoological Station at Naples.

Leipzig.—The Anatomical Society, which has just held its first meeting here under the presidency of Professor Kölliker of Würzburg, now numbers 190 members, including 78 foreigners.

Würzburg.—Dr. K. Rieger has been appointed Extraordinary Professor of Psychological Medicine, and Senior Physician of the Julius Hospital.

EFFORTS are being made to procure the insertion in the Theatres Bill which is now before Parliament, and which it is expected will be read a second time about the middle of June, of a clause to the effect that all exit notices should be in luminous paint. This would greatly facilitate exit, by pointing out the readiest way, especially in cases of total darkness, as when the gas is turned off at the main, which was the cause of the late catastrophe at the Jewish club in the East-end, when seventeen lives were lost in a few minutes. Herr Stehle, the Government inspector of the Royal Bavarian Court Theatre at Munich, where this system is in force, gives high testimony to its efficiency. The insertion into the Bill of such a clause could only be beneficial, and we wish success in their endeavours to those who are advocating it.

THE vigorous measures recently adopted by the authorities with the view of stamping out the serious epidemic of rabies among the deer in Richmond-park have already produced good results. It has been found necessary to slaughter only four animals during the past week, and it is believed that the disease is gradually dying out.

DR. LLOYD ROBERTS has been elected a vice-president of the Obstetric Section, and Dr. Batty Tuke, of Saughton Hall, Edinburgh, has been nominated one of the vice-presidents of the Psychological Section, at the forthcoming International Medical Congress to be held at Washington.

WE learn that an outbreak of typhus has taken place in Carlisle, and that an inspector from the Medical Department of the Local Government Board has, in consequence, visited the town.

ON the 27th inst. a barque arrived in the Tyne from Mobile Bay, the captain and several of the crew of which had died during the voyage from yellow fever.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Barnsley Urban District.—The Barnsley death-rate presents materials for serious consideration. The general rate was for 1886 as high as 29·14 per 1000; that from the seven principal zymotic diseases was no less than 6·16 per 1000; and the deaths under one year of age were at the rate of 205·9 per 1000 of the registered births. Scarlet fever during the past three years has caused 221 deaths, and during last year fifty-three fatal attacks of diarrhœa occurred. With regard to scarlet fever some difficulty was experienced because one large school remained open when the order to close schools under the Education Code was issued. We assume it was not a school receiving any grant of public money, and if so the mischance could not, in the existing state of the law, be avoided. But if it can be shown that under such circumstances the failure to close voluntarily supported schools defeats the objects for which other schools have been compelled to submit to closure, the time will probably come when it will be necessary to ask for more stringent legislation in this matter. But, apart from this, it is not creditable for the borough of Barnsley to be without any means for isolating scarlet fever, especially after the experience they have had as to small-pox. There were twenty-five small-pox deaths in the three years before the present hospital was built; in the fourteen years that have since elapsed there have only been four such deaths, the hospital having served to check the spread of the disease when imported. Some attempt was made to utilise the hospital two or three years ago for a scarlet fever patient, but the result was that small-pox was contracted; the institution, which only has beds for six acute cases, being adapted for the reception of one disease only. It is curious how authorities, who will readily spend the rates in providing means of isolation for small-pox, against which another means of protection is available, cannot see their way to do the same for scarlet fever, which is even more deadly. Compare, for example, the 14 small-pox deaths in three years which led to the provision of a small-pox hospital, and the 221 scarlet fever deaths in the last three years, which have produced no corresponding result. Dr. Sadler recommends public subscriptions to fill up this serious gap in the sanitary defences of Barnsley. In connexion with the grave diarrhœa mortality, we would urge much more rapid action as regards the present dangerous and filthy ashpit system. Warm weather does not necessarily kill children with diarrhœa, but children inhaling the disgusting emanations from receptacles containing stored refuse, which tends to saturate air and soil, are those, above all others, who are subject to such premature death. Barnsley has made substantial sanitary progress, but this last year's heavy death-rate has indicated the need for further action in more directions than one.

Stafford Urban District.—After a careful estimate of the present population, Dr. Milnes Blumer puts the birth-rate for 1886 at 35·5, and the death-rate at 17·7 per 1000. The deaths under one year were at the rate of 120 to every 1000 births registered. During a measles epidemic the plan of requiring school closure was not followed, the alternative of prohibiting the attendance of children from infected houses having been regarded as better calculated to effect the desired object, and it is stated that when the step was resorted to the disease began to subside. In connexion with the tub system, it had been suggested that in order to deal with the nuisance accompanying the collection of tubs the carts should go round at night instead of in the daytime. We do not believe this is right in principle. Tub collection can be arranged with a minimum of nuisance if proper carts and tub-covers are provided; and under any circumstances nuisance will not be remedied by doing the work under cover of darkness. There is no need to do the work in the busy hours of the day, but it should not be commenced until about sunrise. A good deal of excellent sanitary work is being steadily carried out in the district; substantial progress has been made with the new waterworks, which will shortly be in operation; and such places as bakehouses, common lodging-houses, and slaughter-houses, are both looked after and dealt with when the need for action is shown.

Belper Rural District.—Mr. J. Allen has the satisfaction of reporting a steady diminution in the rate of mortality, which stood at its highest point—namely, 17·5 per 1000—in 1879, and is now 13·8. There are, however, points to which attention is needed in the district. One relates to infant mortality, and Mr. Allen significantly refers to the relation of this mortality with those assurance companies which, by way of a grim joke, are locally known as "Death" clubs, the death so often being associated with neglect. He also urges the need for hospital provision, especially in the interests of the working classes, who, when infectious disease prevails, are unable, like their more wealthy brethren, to leave the district for a time. Holbrook and Kilbourne are still without a system of drainage, and this tells on the death-rate of the former place. One sewage outfall nuisance which had led to bitter feelings between two contending sets has been satisfactorily dealt with through the judicious handling of Major Tulloch of the Local Government Board. The voluntary system of notification of infectious diseases which is in force bids fair to break down. It is hinted that this may be due to the inadequacy of the fee offered. The usual fee in most parts of the country is half-a-crown per certificate granted, and it should not be less in the Belper district.

Crickhowell Rural District.—Powers have been granted for supplying the town of Crickhowell with a water service, and Mr. Philip Hill makes some apt remarks on the principles which should govern the authority in their action in this matter. He has more than once brought under notice the grave state of the sewer outfall, and the greasy, black, and foul mud which results, to which attention was recently drawn by Mr. Spear, of the Local Government Board. Slaughter-houses, cow-houses, and adulterations under the Food and Drugs Act are all receiving attention, and special reference is made to the unhealthiness of many dwellings by reason of dampness, excessive cold from draughts, and impurity of air from closet and other effluvia. The death-rate was high in 1886—namely, 22·7,—even if allowance is made for the fact that the workhouse deaths included several non-residents which it was not possible to allow for with accuracy.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6428 births and 3825 deaths were registered during the week ending April 23rd. The annual rate of mortality in these towns, which had been 20·5 and 20·9 per 1000 in the preceding two weeks, further rose last week to 21·6. During the first three weeks of the current quarter the death-rate in these towns averaged 21·0 per 1000, and was 2·6 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 14·9 in Birkenhead, 15·7 in Leicester, 15·8 in Nottingham, and 16·3 in Brighton. The rates in the other towns ranged upwards to 27·7 in Halifax, 27·9 in Cardiff, 28·7 in Liverpool, and 36·4 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the ten preceding weeks from 340 to 510, further rose last week to 558; they included 291 from measles, 134 from whooping-cough, 47 from scarlet fever, 40 from diarrhœa, 24 from "fever" (principally enteric), 21 from diphtheria, and only 1 from small-pox. These zymotic diseases caused the lowest death-rates last week in Portsmouth, Wolverhampton, and Halifax; and the highest rates in Norwich, Salford, and Manchester. The greatest mortality from measles occurred in Norwich, Huddersfield, Salford, Liverpool, and Manchester; from whooping-cough in Norwich, Birmingham, and Nottingham; and from scarlet fever in Blackburn. The 21 deaths from diphtheria in the twenty-eight towns included 14 in London, 3 in Liverpool, and 2 in Derby. Small-pox caused 1 death in Greater London, but not one in any of the twenty-seven large provincial towns. Only 7 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; 2 new cases were admitted to these hospitals during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding four weeks, from 509 to 363, further fell last week to 337, and were 74 below the corrected average. The causes of 22, or

Digitized by Google

2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Leicester, Portsmouth, and Derby. The largest proportions of uncertified deaths were registered in Preston, Sunderland, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·9 and 23·7 per 1000 in the preceding two weeks, declined to 22·0 in the week ending April 23rd; this rate exceeded, however, by 0·4 the mean rate in the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 11·5 and 12·3 in Leith and Greenock, to 25·8 in Glasgow and 29·9 in Paisley. The 550 deaths in the eight towns last week showed a decrease of 43 upon the number in the previous week, and included 36 which were referred to whooping-cough, 30 to measles, 10 to diarrhœa, 9 to scarlet fever, 8 to "fever" (typhus, enteric, or simple), 2 to diphtheria, and not one to small-pox; in all, 95 deaths resulted from these principal zymotic diseases, against numbers declining in the preceding four weeks from 127 to 91. These 95 deaths were equal to an annual rate of 3·8 per 1000, which exceeded by 0·7 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 31, 33, and 36 in the preceding three weeks, were again 36 last week, of which 14 occurred in Glasgow, 6 in Edinburgh, 5 in Dundee, and 5 in Aberdeen. The 30 deaths from measles showed an increase of 2 upon the number in the previous week, and included 18 in Aberdeen and 11 in Glasgow. The fatal cases of scarlet fever, which had been 11 and 10 in the previous two weeks, further declined last week to 9, of which 4 occurred in Dundee, 3 in Edinburgh, and 2 in Glasgow. The 10 deaths attributed to diarrhœa showed an increase of 3 upon the low number in the previous week, and exceeded the number in the corresponding week of last week by 1; they included 4 in Glasgow and 3 in Aberdeen. The deaths referred to "fever," which had been 8 and 6 in the previous two weeks, rose to 8 last week, and included 3 in Glasgow and 2 in Dundee. The deaths from acute diseases of the respiratory organs in the eight towns, which had been 110 and 126 in the preceding two weeks, were 124 last week, and exceeded by 24 the number in the corresponding week of last year. The causes of 57, or more than 10 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 30·0 and 34·1 per 1000 in the preceding two weeks, declined again to 31·3 in the week ending April 23rd. During the first three weeks of the current quarter the death-rate in the city averaged 31·8 per 1000, the mean rate during the same period being but 18·7 in London and 19·3 in Edinburgh. The 212 deaths in Dublin last week showed a decline of 19 from the number returned in the preceding week; they included 6 which were referred to measles, 4 to "fever" (typhus, enteric, or simple), 3 to diarrhœa, 2 to scarlet fever, 2 to diphtheria, 2 to whooping-cough, and not one to small-pox. Thus 19 deaths resulted from these principal zymotic diseases, against 15 and 22 in the preceding two weeks; they were equal to an annual rate of 2·8 per 1000, the rates from the same diseases being 2·4 in London and 2·0 in Edinburgh. The 6 fatal cases of measles showed a decline of 1 from the number in the previous week, and those of scarlet fever, whooping-cough, and "fever," were also fewer than those returned in the previous week. The deaths from diarrhœa and diphtheria, on the other hand, showed an increase. The deaths of infants showed a marked decline, while those of elderly persons showed an increase upon recent weekly numbers. Five inquest cases and 2 deaths from violence were registered; and 56, or more than a quarter, of the deaths occurred in public institutions. The causes of 39, or 18 per cent., of the deaths registered during the week were not certified.

AT a vestry meeting held at St. Mary's, Reading, on the 19th inst., it was resolved that an address be presented to Mr. Isaac Harrinson, in recognition of his efforts to improve and beautify the town.

THE SERVICES.

Deputy Surgeon-General J. B. C. Read, C.B., has joined the Home District for duty.

Deputy Surgeon-General J. Tulloch, M.D., has assumed the duties of Principal Medical Officer at Woolwich.

Deputy Surgeon-General R. A. Chapple has been appointed Administrative Officer, Mhow Circle.

Surgeon-Major W. Taylor, M.D., has been appointed to the Staff of the Commander-in-Chief in the East Indies, and has been placed on the Supernumerary List.

WAR OFFICE.—Surgeon-General Thomas Graham Balfour, M.D., F.R.S., retired pay, to be Honorary Physician to the Queen, vice Surgeon-General W. Rutherford, M.D., C.B., deceased (dated April 23rd, 1887).

ARMY MEDICAL STAFF.—The undermentioned Surgeons to be Surgeons-Major (dated March 31st, 1887):—Henry Charlesworth, John Cotter Dorman, M.B., George Herbert Le Mottée, M.D., William Litchfield Chester, M.B., and Edward Arthur Mapleton, M.B.

ADMIRALTY.—The Greenwich Hospital pension of £50 a year for fleet and staff surgeons, vacant by the death of Dr. Gerald Yeo, has been awarded to Fleet Surgeon William G. J. Ayre.

Deputy Inspector-General of Hospitals and Fleets John Fisher has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet (dated April 1st, 1887); Fleet Surgeon Henry Frederick Norbury, C.B., has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet (dated April 1st, 1887).

In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Eugène Victor de Méric has been placed on the Retired List of his rank.

The following appointments have been made:—Surgeon Alfred T. Rimell, to the *Rattlesnake* (to date from 28th inst.) Fleet Surgeon Henry S. Lander, to the *Impregnable*; Staff Surgeon M. Fitzgerald, to the *Triumph*, for Esquimault sick quarters; Staff Surgeon O. P. Browne, to the *Caroline*; and Surgeon C. D. D. E. Chamberlain to the *Rattler*.

ROYAL NAVAL ARTILLERY VOLUNTEERS (London Brigade). Edmund Distin Maddick, Esq., to be Honorary Surgeon (dated April 20th, 1887).

YEOMANRY CAVALRY.—Oxfordshire: Surgeon Frederick Taylor resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the Regiment on his retirement (dated April 27th, 1887).

ARTILLERY VOLUNTEERS.—1st Caithness: James Leith Waters, M.B., to be Acting Surgeon (dated April 27th, 1887).—8th Lancashire: Surgeon T. F. Morrish resigns his commission (dated April 27th, 1887).—Newcastle and Sunderland: Henry S. Baumgartner, M.B., M.S., M.R.C.S., L.S.A., to be Acting Surgeon.

RIFLE VOLUNTEERS.—3rd Cheshire: Theodore Fennell, Gent., to be Acting Surgeon (dated April 27th, 1887).—1st Volunteer Battalion, the Duke of Cornwall's Light Infantry: Acting Surgeon E. S. Angove resigns his appointment (dated April 27th, 1887).—6th Lanarkshire: William Brown Moir, M.D., to be Acting Surgeon (dated April 27th, 1887).—1st Renfrewshire: Acting Surgeon T. Philip, M.D., to be Surgeon (dated April 27th, 1887).

THE VOLUNTEER MEDICAL STAFF CORPS.—The London Division: John Adam Watson, Gent., to be Surgeon (dated April 2nd, 1887).

THE VOLUNTEER MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—I regret to be obliged to point out to you an alteration now necessary in regard to a statement in your annotation in THE LANCET of a recent date on my paper on "The Volunteer Medical Service in Peace and War."

I have just been officially informed that the permission granted me last November to join the School of Instruction at the Medical Staff Corps Depôt at Aldershot under the usual regulations as to allowances &c. has been rescinded, and that such permission will not in future be granted to regimental surgeons, but only to surgeons of the Volunteer Medical Staff. I regret the matter the more because it seems to me that one of the difficulties most strongly deprecated by the promoters of the Volunteer Medical Staff Corps is now arising by the drawing of a most invidious distinction between the officers of that corps (and, indeed, all other commissioned officers) and the surgeons carried on the Regimental Lists. I am, Sirs, yours faithfully,

W. P. MEARS, M.D.,
Surgeon, Tynemouth Artillery.

Newcastle-on-Tyne, April 25th, 1887.

Correspondence.

"Audi alteram partem."

THE MANCHESTER *VERSUS* THE LONDON SCHOOLS OF MEDICINE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 26th there is an editorial annotation dealing with the question of degrees for London medical students, in which the following remark occurs: "It is difficult to understand the position of the Colleges [of Physicians and Surgeons] in putting into the foreground of their claims the advantages and superiority of clinical teaching and clinical opportunities in London, if some residential period is not insisted on." Beyond what appears in this statement in your own columns, I must confess that I am ignorant of any such claim to superiority having been advanced in favour of the London schools. Nor is the precise meaning which the words are intended to convey to be found on the surface. If it be that throughout the length and breadth of London there are to be found clinical teachers and material for clinical instruction which, if they could be focussed and made available for the instruction of all London students, would be superior to any to be found elsewhere, then we of the provinces can afford, with much complacency, to admit that it is so. If, on the other hand, it means that, as the London schools are at present constituted and the teaching at present carried on, this same superiority over provincial schools is to be recognised, then I think it will be admitted that there are good grounds for provincial jealousy being aroused and for a wish to hear something further on the subject.

It happens that a few weeks ago I made some remarks at the close of a clinical lecture which were curiously at variance with any such idea, and your article thus immediately arrested my attention. Of other provincial schools I cannot, of course, speak; but so far as that of Manchester is concerned, as a teacher of clinical surgery in it, I feel strongly disposed to controvert the alleged contention of the Colleges in respect of every individual subject of clinical study. I believe it would be possible to show that, whether in the mere passing the tests of the examining boards, in the competition for prizes, or in general equipment for the responsibilities of practice, the Manchester student holds his own with the Londoner; and, further, in respect of clinical opportunities, that there is scarcely a school in London which can provide such a fullness of material as our own, whether in general medicine and surgery, or in the special departments of fever, insanity, ophthalmology, or the diseases of women and children. It would entail some little trouble, however, to go into this fully, and, after all, I wonder very much whether any such claim on behalf of the London schools as that referred to has ever been seriously made. I can scarcely think it possible that so much ignorance of the resources of Manchester as this would represent really exists in the Councils of the two licensing Colleges. I will therefore content myself at present with a few data which are at once accessible to me, with a view to giving a little information to those concerned, whether that information be really needed or not.

Two allegations are contained in your article: firstly, that the clinical teaching in the London schools is superior to ours; and, secondly, that the clinical opportunities are likewise superior. With regard to the first of these, it is perhaps difficult to adduce direct proof without making references which might appear invidious. A fair test, however, of the quality of the teaching may be found in the achievements of the pupils, and probably the results of competitive examinations would be as good an indication as could be obtained did the students from the schools concerned enter for such examinations in equal proportions to their total numbers. The honours examinations of the University of London would afford an excellent example for our purpose, were it not that it is undoubtedly more a matter of course for a London student to prepare for these than it is for a Manchester student, and therefore a larger proportion of the total number of the former probably enter than of the latter. Still, this is the only examination which seems to give any indication of the required information, and as it has been somewhat fashionable of late years for our men to read for the London degrees, I propose to accept this as the test we are in quest of. For this purpose I asked Dr. Wm. Thorburn, the surgical registrar of the Royal Infirmary, himself one of our most distinguished students, to look out for me the results of the honours division of the pass examinations for the last six years. Unfortunately those for 1886 are not yet published, but he has been good enough to furnish me with those for the previous five years. I need not give the several years separately, but will sum them up, and the result appears as follows:—

Second M.B. Examination (Honours).

MEDICINE.		OBSTETRICS.		FORENSIC MEDICINE.	
Manchester.	All other schools.	Manchester.	All other schools.	Manchester.	All other schools.
11 ...	77	3 ...	54	6 ...	71

At this examination, during the same five years, fifteen scholarships were given, of which Manchester obtained three, and fifteen gold medals were given, of which Manchester obtained six. At the B.S. examination in 1884, the only one of these years in which honours were given in surgery, Manchester obtained two out of six, and also took both the scholarship and gold medal, no other men being in the first division. At the M D. examination Manchester took the gold medal in 1882. When it is borne in mind that the total proportion of students in Manchester to those of London alone is as one to eleven, I think it will be admitted that this record is one that we may be fairly satisfied with. How many of the London schools can equal it?

Then, with regard to the second allegation, that of superiority of the London schools in clinical opportunities, a little trouble in the collection of figures would probably show that very few of the London hospitals can compare with Manchester in richness of material. But knowing so little of the circumstances under which the claim alluded to has been brought forward, and therefore of the importance to be attached to it, I am unwilling to engage in what is always to me an ungrateful task. At the risk of appearing egotistical, I therefore propose to limit myself almost entirely to the work of my own wards, as illustrating the work of the whole surgical department of our infirmary. Probably, without entering into tedious statistics, a fair criterion of the "clinical opportunities" of a surgical hospital is to be found in an examination of the operations performed in it. My house-surgeon, Mr. Seville, has accordingly supplied me with the following information. Since I became full surgeon, or rather since November, 1882—say, four years and a half,—1054 operations have been performed in my wards, about five every week. These were operations such as have usually to be performed in the theatre, as distinguished from small operations done in bed; but as an indication of their nature I will specify particularly those of the past month of March. They were as follows:—Scraping of lupus (2), amputation of leg, ditto of breast, excision of knee (2), ditto of hip, ditto of lymphatic glands (2), ditto of cystic thyroid, ditto of sebaceous cysts, ditto of necrosed bone (2), fistula in ano, Dupuytren's contraction, aspiration of diverticulum of knee-joint, rhinoplasty, cleft palate (2), compression for popliteal aneurysm, extraction of catheter from bladder, division of adherent ulcer, resection of ribs for empyema, suturing wounds of face, reduction of dislocated hip, taxis for strangulated hernia, vesico-vaginal fistula—a good month's work, but, happily, not encountered every month of every year. Yet, at the same time, where there is so much to be seen, one frequently meets with "runs" of cases affording excellent opportunity for teaching purposes. For example, in my last "accident" take-in week we admitted six cases of fracture of the femur, one of dislocation of the hip, and one of bruise of the hip simulating fracture of the neck. Again, some eighteen months ago I had on one operation day five cases of possible amputation in the thigh. Three were so amputated, in one excision of the knee was performed, and one was declined (senile gangrene). Once more, a short time ago one of my colleagues had three cases of lithotomy in one morning.

The above represents less than one-fourth of the in-door surgical work of our infirmary, for besides three colleagues with the same number of beds as myself, the two assistant-surgeons have some beds at their disposal. Then, in addition to all this, there is the vast field of observation in the out-patient and accident rooms, in which no fewer than 14,000 cases were treated during the year ending June, 1886. The former of these departments, under the charge of the

Digitized by Google

assistant-surgeons, is, indeed, a mine of instruction and experience to the student, of which the value can scarcely be over-estimated. The simple fact is that in every department of the hospital there is always a plethora of material for teaching purposes, and the veriest glutton, hungering and thirsting after knowledge, can only partake of a portion of what is daily set before him.

So much for surgical work only. Possibly, with your permission, some further information may at another time be given as regards our clinical opportunities in other departments. The present instalment will, however, demonstrate on what substantial grounds we may contest the claim adduced on behalf of the metropolitan schools.

I am, Sirs, yours truly,

Manchester, April, 1887. JAMES HARDIE.

THE MEDICAL STAFF AND RANK.

To the Editors of THE LANCET.

SIRS,—My chief reason for now addressing you is the underlying inference of your recent annotations and the letter of a recent correspondent that the medical staff in asking for rank is departing from its proper status as a professional body; and if you will allow me, I will try to make our views (or, at least, those of a section) plain. The question is admittedly not one of personal likes or dislikes, but rather what is necessary to honestly and efficiently carry out the duties entrusted to us. In itself we care nothing for military rank, and to anyone so inclined it can be reached through the ordinary portal for the combatant officer far easier and with less expenditure of brains and money than through the doubtful and indirect mazes of the medical staff; it is not that we regard our profession as secondary to any other, but rather that, valuing it highly, and seeing how, in developing, its threads ramify through all the segments of the military machine, we desire reasonable freedom and a defined position for our labours. There are many among the older members (and I am myself among the number) who viewed with personal dislike departures ultra-professional taken step by step, until now we have work to do identical with that of the combatant officer; but we cannot but acknowledge that this is the normal sequel of unification, and the logical and necessary outcome of our present duties is *rank*. If anyone suppose that, as at present placed, we are merely medical men charged with care of sick, let him run his eye over the medical regulations of the army detailing also sanitary work, charge of stores, command of Medical Staff Corps, which embraces duties as essentially military as any that a combatant officer can be called upon to do. These are the duties which during peace, and doubly so during war, call for a defined status for the responsible individual; one not liable to disturbance through the jealousies of the combatant ranks, or by personal interpretations of orders and warrants, and whittlings and twistings to meet a given end. It was utter absence of all trust and faith in the acts of the military towards the medical staff which constituted the motive power in the recent outcry over relative rank, and it is this which now makes us look with more than doubtful eyes over the proposed amendment of the paragraph which almost word for word repeats the preceding paragraph on honorary rank, while stopping short of the logical step of granting the latter.

The present disturbance is not our act, it has been thrust upon us; and now that the Secretary of State for War has told us (much to our astonishment) that relative rank is a meaningless phrase, we cannot but see in our present state a condition fraught with misunderstanding and friction with other segments, and with probable failure when next tested in the field. We seem to have come to the parting of the ways; the better we are professionally the less we feel the possibility of contentedness; and what we now ask for is that the War Office should know its own mind and give us fair play. If our work is to be limited to purely professional topics, we can regard our then position as medical men in Government employ with complacency. What suffices for the chaplains will suffice for us, with stripping of our trappings and gaudy uniforms, spurs, swords, and salutes, the complements of different military ranks—all a pure mockery to rankless men and an obstacle in attendance on sick men. If, however, unification is to normally evolve, we cannot but be an integral part of the military machine, and our status must be defined in it on the only recognised method—rank; and experience has now shown that this system carried out to its logical conclusions contains elements of the greatest value to the Army, State, and even also to the medical profession. It entails ultra-professional duties, and necessitates a designation embracing them; but the latter need not disturb our peace of mind, as it already exists in three of our present grades. Moreover, in a department complete in itself, some of us think we see an escape from the blot, which you so forcibly put forward in your issue of the 23rd instant—award of honours for service centred in the military head; and you do us a kindness in giving it prominence. To speak plainly, it is nothing short of a disgrace, it saps all loyal feeling towards our departmental superiors, it stifles the growth of all professional culture and progress. But will not unity, strength, and proper recognition of us as *military* medical officers performing multiform duties carry also proper and due authority and influence of our head among the other heads of the army sections, and a dominant (if not sole) influence in the internal economy of the department, including promotion as well as rewards? and will not division of our present work into professional and ultra-professional, with outside men and officers to carry on the latter, by so much deprive us of weight in the military sphere, and equally reduce the influence of our head on the points mentioned? The present blots are relics of the past, of a time when our duties were more strictly professional than they now are, and when the head possessed a lessened importance; and it seems to some of us that our present position without rank and the misplaced power over awards and promotion await the same solution—emancipation from the unreasonable supremacy in our affairs of the military caste. I am, Sirs, yours truly,

April, 1887. ONE OF THEM.

*** We have much pleasure in inserting the above letter from a distinguished officer of the Medical Department, though we cannot quite agree with the writer on some of the points he advances.—ED. L.

THE LUNACY BILL, 1887.

To the Editors of THE LANCET.

SIRS,—The new clause inserted on Feb. 22nd last into the Lunacy Bill of the present year, at the instance of Lord Monkswell, to the effect that "when any officer is transferred from one county asylum to another his service in all such asylums shall count for the purpose of computing the pension or superannuation allowance," is good so far as it goes. But there are officers who have served a sufficient number of years to earn a pension whose service has not been confined alone to county asylums, who have transferred their services from one of the county asylums to one of the borough or metropolitan district asylums, or *vice versâ*. Those gentlemen will naturally be of opinion that, in fairness, the operation of the clause in question ought to be extended to them. It will not, I venture to say, be contended that the work in the borough or district asylums is less anxious, onerous, and responsible than it is in the county asylums, and, moreover, probably one effect of the exclusion of the officers serving in them from this pension clause would be to deter the best men at present serving in the county asylums from offering themselves for such appointments in future.

I am, Sirs, your obedient servant,

Malling Place, Kent, April 23rd, 1887. JAMES ADAM, M.D.

THE ERASMUS WILSON BEQUEST.

To the Editors of THE LANCET.

SIRS,—I venture to think that the petitions which have been lately presented to the Council of the Royal College of Surgeons by persons desirous of the suppression of experiments on living animals place the question of the disposal of the funds which have accrued to the Royal College of Surgeons in a new aspect. Before these expressions of opinion by a section of the public, any disposition of the funds of the Erasmus Wilson bequest was a matter of interest mainly to the body into whose hands they had fallen, and in a secondary degree to the medical profession in general. The decision must now lie between the opinions of the leaders of the profession, as expressed in the largely

Digitized by Google

signed memorial presented to the College of Surgeons in March last, and the opinions of that section of the public which is opposed to experimentation on living animals under any circumstances whatever. I have not any doubt that the verdict which must be pronounced by the Council of the College of Surgeons will be favourable to the interests of suffering humanity, by affording increased opportunity for the research into the origin of disease by properly qualified experimenters. But the question has now come to be the decision of a medical corporation as to the necessity for experimental research; and should the decision be adverse to what is believed by far the majority of medical men to be essential for the advancement of medical science, I cannot but think that a blow of the greatest force will have been struck against the prosecution of experimental physiology throughout the kingdom.

I am, Sirs, yours obediently,

Oxford, April, 1887. W. TYRRELL BROOKS.

PUNCTURING THE ABDOMEN IN PUERPERAL CASES.

To the Editors of THE LANCET.

SIRS,—Dr. Priestley raises the question of puncturing the abdomen for extreme flatulent distension in puerperal diseases. The following case came under my care:—

Mrs. W—— (seen Nov. 6th, 1875) was confined to bed in the seventh month of pregnancy, with vomiting, dropsy, and albuminous urine (nearly one-half on testing). On Oct. 5th she was prematurely confined; labour natural. Vomiting persisted after confinement, and a severe febrile state followed, with flatulent distension of the abdomen as a chief symptom. This increased during the next few days, and on the night of the 12th, the distress being so great. I punctured the bowel (Mr. E. Jackson being with me) with a fine trocar. Flatus and some yellow fluid escaped. Relief was given, and the patient, after some weeks of illness, recovered, the albumen entirely disappearing. No inconvenience of any kind followed the operation, and the patient has enjoyed good health since. The distension returned after the operation; but was not so extreme, and the puncturing was not repeated. I am, Sirs, yours truly,

Manchester, April 25th, 1887. STEPHEN NESFIELD, M.D.

THE CONGRESS OF GERMAN PHYSICIANS.

(*From a Correspondent.*)

THE sixth Congress of German Physicians (Congress für innere Medizin) took place in the splendid rooms of the Kursaal, Wiesbaden, on April 13th, 14th, and 15th. Amongst the celebrities present were Virchow, Leyden, Gerhardt (Berlin), Leube (Würzburg), Curshmann (Hamburg), Binz (Bonn), Filehne (Breslau), Hitzig (Halle), Kopbach (Jena), Nothnagel (Vienna), Liebermeister and Jürgensen (Tübingen), Verstraten (Ghent), Kisch (Prague), and the late assistant of the celebrated Cohnheim, Lichtheim, now professor at Berne.

Leyden, as president, opened the meeting. Remarking on the growing importance of the Society, he urged the necessity of a union of all physicians in view of the increasing tendency towards specialism.

Dettweiler and Penzoldt spoke of the treatment of consumption, and both came to the conclusion that, in spite of the great hopes based on the discovery of Koch's bacillus, we are yet far from having discovered a remedy for the dire disease, and have still to rely on palliative measures. Kuehle laid stress upon the fact that tuberculosis is far more often originated by direct infection from mouth to mouth than is usually believed, and he even went so far as to speak of a "family tuberculosis" in this sense of propagation.

Lichtheim made some very interesting and practically important remarks on the etiology of pernicious anæmia, relating some cases in which there was a coincidence of tabes and this disease and an evident connexion with intestinal worms (bothriocephalus, filaria).

Rindfleisch of Würzburg advanced a new theory with regard to tabes dorsalis, basing it on a very ingenious experiment. According to this observer, the thickening of the pia mater is the primary affection, having for its effects the compression and degeneration of the posterior cords, which are more liable to be compressed than the other parts of the medulla.

Vogel (Munich) and Hagenbach (Basel) spoke of the treatment of whooping-cough, and, reviewing the various belauded remedies, they recommended a larger recourse to morphia as an antispasmodic, besides quinine (as many decigrammes as the child has years), and the local irritation of the nose advocated by Michael of Hamburg according to the experience of Hauck. But they regretted that in statistics connected with the effects of remedies there is not taken into due account the age of the child, the prognosis in no disease being so much influenced by the age as in whooping-cough. So with regard to the mortality, which, according to Vogel, is as follows: under one year 25 per cent.; from two to five 4·8 per cent.; and over five years only 1·1 per cent.

Nothnagel and Naunyn (Königsberg) were the exponents of the difficult question of the localisation of brain diseases, more especially with regard to the cortex. The latter could confirm the observations of Wernicke and Kussmaul concerning aphasia.

Litten (Berlin) laid stress upon the fact that diseases of the stomach are very often associated with malposition of the right kidney (seventeen out of his thirty-two cases), and not exclusively in women. He considers the gastric dilatation as the primary cause, and has obtained excellent results by washing out the stomach.

Adamkiewicz (Cracow) stated that he had cured several acute cases of neuralgia (supra-orbitalis) by employing a combination of chloroform and the galvanic current, and explained its immediate effects by the way of kataphoresis. This experiment is certainly worthy of attention.

Very interesting were the observations of Finkler upon a typhoid fever epidemic in a small town near Bonn, where he could trace most accurately the path of the infection. After this Professor Fraenkel of Berlin drew attention to the long vitality of the typhoid fever bacilli of Gaffky in the intestine, and he explained by this circumstance the occurrence of late infection and of relapses. Rossbach made some observations on chyluria and leucocytosis. He also exhibited a chair for the use of asthmatics and patients suffering from emphysema (*Athmungsstuhl*), invented by a patient of his, by means of which the expiration is aided by an elastic compression very easily manageable.

Cahn, assistant at Strassburg, denied the assertions of Riegel that in the carcinomatous stomach hydrochloric acid does not exist, but proved that in certain cases there is carcinoma with HCl., and yet the reaction of methyl violet, or congo, or tropæolin may be wanting.

Of very far-reaching and undoubtedly also practical importance will prove the experiment of the young professor, von Mehring, of Strassburg, who produced diabetes on fasting dogs by large doses of florhidein, an extract of the roots of the plum-tree, and who expressed his conviction that the sugar is formed solely by decomposition of albumen. These researches and operations seem worthy of special notice, as they are calculated to profoundly modify the views held of this disease. Leube congratulated von Mehring, and gave expression to the hope that we might now succeed in getting animals continuously diabetic.

Franz spoke of a question which is in Germany very much discussed, and has, indeed, become a burning one since the suggestions of Oertel—viz., whether rest or exercise is to be recommended for patients with heart disease. Leyden took part in the discussion, stating that many practitioners go too far in their anxiety for the safety of such patients, and he referred to the reports of Sir Andrew Clark, who has seen in his practice more than 600 cases of heart diseases without any bad symptoms during five years. In conclusion, Leyden expressed the hope that the next Congress, which will meet again in the beautiful queen of German watering-places, may be equally well attended.

Weisbaden, April, 1887.

THE GERMAN HOSPITAL.—On the 27th inst. the forty-second anniversary festival of this institution, which is situated at Dalston, was held at the Hôtel Métropole, the Duke of Cambridge in the chair. During the evening the secretary announced donations and subscriptions amounting to £3409, including £200 from the Emperor of Germany, £50 from the Emperor of Austria, £20 from the Chairman, and £105 from the Corporation of the City of London.

LIVERPOOL.

(From our own Correspondent.)

HOSPITAL SATURDAY.

SATURDAY, May 7th, is to be our Hospital Saturday this year, and two circumstances combine to give great interest to this year's collections. The first is the steadily growing practice of making weekly collections among large bodies of working men, the aggregate of which is realised on Hospital Saturday. The second is the honest rivalry in this good work which it is believed will be manifested this year among the workmen belonging to the different trades. The two circumstances will be enhanced by the improvement which has been observed in some branches of trade, of which it is hoped that the hospitals may feel the benefit.

THE LOCK HOSPITAL.

The hospital has been closed against all venereal cases, it being required temporarily by the committee of the Royal Infirmary, under whose management it is while the present infirmary is being taken down and a new one erected. Meanwhile many greatly needed repairs and alterations are being effected, and when the new infirmary is completed the surgeons of the hospital will be enabled to return to it with increased comfort to themselves and their patients.

ANOTHER SWING-BOAT FATALITY.

An inquest was held at St. Helens on the 25th inst. on the body of a boy who was killed accidentally by a swing-boat. It appeared that on the previous Saturday (23rd inst.) he, with a large number of other children, were playing on some land where were a number of whirligigs and swing-boats. One of the occupants of a swing-boat which was in motion having dropped his cap, the deceased ran to pick it up, when he was struck on the right side of the head by the boat and picked up insensible with a fractured skull and part of the brain protruding. He was attended by Dr. Reid, but died the following day. The deputy coroner remarked that "accidents of this kind were so common that wherever swing-boats went coroners had to follow." Some of the jury suggested the putting of a rope or fence round the boats, but the deputy coroner thought that the latter should be suppressed altogether, in which opinion the jury concurred.

SAD RESULT OF VIEWING A BODY.

A young man residing in Warrington went on the 24th inst. to view the body of a woman which had been found floating in the Saukey canal, under the impression that it might be that of his mother, who had been from home for a week attending to a sick relative. He was much excited and impressed with what he saw, and, being somewhat weak in mind, he became quite delirious and almost unmanageable. In spite of every precaution, he escaped from the house, and subsequently was found drowned in a clay-pit near.

A FATAL FOOTBALL ACCIDENT.

An inquest was held at Widnes to-day on the body of a boy aged twelve, who died on Saturday last from the effects of a kick on the shin, received while playing football on the 11th inst. He did not complain until the following day, and medical advice was not sought until the 19th inst.

Liverpool, April 26th.

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY GENERAL COUNCIL.

THE statutory half-yearly meeting of the University Council held last week was of a more than ordinarily interesting character. Of late there have been evidences that this body, composed of the graduates of the University, is increasingly anxious to assert its right of forming an integral part of the University polity, and of exercising such powers as legally belong to it in shaping the course of academic development. As it was understood that questions affecting these subjects were to be discussed at the meeting, the attendance was a large one; the professoriate in particular, showing much greater interest than usual in the proceedings, was largely represented. The first business of the meeting was a communication to the Chancellor from the Prince of Wales in regard to the Imperial Institute scheme, placing its advantages before the members of the University, and bespeaking their personal interest in its support. A resolution was unanimously adopted that a loyal address should be presented to the Queen, congratulating Her Majesty on the jubilee of her accession about to be happily celebrated. The next business was the appointment of an assessor to represent the General Council in the University Court, the supreme governing body of the University. This office is now vacant through the lamented death of Dr. Rutherford Haldane. Sir Alexander Christison and Dr. Heron Watson were nominated for the office, and a division was at once taken. There voted for the former 70, and for the latter 63; but the result of the vote was challenged by Dr. Watson's proposer, who requested a poll of the whole constituency. This was agreed to. After a discussion on some proposed changes in the system of arts graduation, an important question touching the representation of the University in the General Medical Council was raised, and very warmly discussed. It was contended, and put in the form of a recommendation to the University Court, that the Court should memorialise the Government that the term "University," as used in the Medical Act in regard to the election of a representative on the General Medical Council, should signify the "Council," including all University graduates, and not the "Senatus," as it has been till now interpreted. A somewhat stormy discussion ensued, in which Sir William Turner appeared as the champion of the interests of the Senatus. In a somewhat melodramatic scene, in the face of considerable dissent and interruption, he iterated and reiterated the statement that "the Senatus Academicus is the administrative body of the University under the Universities Act." By a reference to the mode of representation of other bodies, he showed that all analogy was in favour of the election of the representative by the Senatus. Ultimately his amendment to the original motion recommending to the Court the consideration of the sound interpretation of the Universities and Medical Acts in the point raised was accepted by the Council.

THE COUNCIL ASSESSORSHIP IN THE UNIVERSITY COURT.

Owing to the nomination of two candidates for this important office, an active canvas in behalf of both is now proceeding, and the voting papers have been already issued. The election ends on May 10th, before which date the ballot papers must be returned to the University registrar. Both Sir Alexander Christison and Dr. Heron Watson are so well known and widely esteemed, and each in many points of view is so well qualified for the office, that the contest is fraught with an unusual degree of interest, and public opinion is strongly divided in the matter. The question of general politics fortunately does not enter into the contest, nor is there any element of rivalry as between two of the learned professions, as both candidates are distinguished graduates in medicine; but the issue at stake is for the most part one of the balance of power between two bodies in the University, for Sir Alexander Christison is as closely identified by his antecedents and in his nomination and support with the Senatus and an oligarchical system of university administration, as is Dr. Heron Watson by his position as a successful extra-mural teacher and his advocacy of an expanded system of professional education with the University Council Association and with university reform. This issue is, of course, one that has long been pending, and one in which increased interest has been from time to time developed by passing events; but it is brought into special prominence at the present time by the fact that the new Universities Bill is now being drafted and will shortly be before Parliament, whence the absolute importance to all parties of as strong a representation as possible of their specific requirements at the governing board of the University.

GOVERNMENT AID FOR SCIENTIFIC RESEARCH.

During a recent visit of Lord Lothian, the Secretary for Scotland, to Edinburgh, he was interviewed by a deputation of scientific men representing the Royal Society of Edinburgh in regard to the position of science in this country, and the almost complete absence of Government subsidies for its support. Sir William Thomson introduced the deputation and spoke on the general question of Scottish

Digitized by Google

claims, pointing out the extraordinary inequality in the grants under the present system as furnished to Scotland and England. To put the matter practically, he suggested that his lordship should claim an annual grant of £2000 for Scotland, one-tenth of the sum annually administered in London. He was supported by Mr. John Murray and Professor Chrystal, who drew particular attention to the establishment of the Ben Nevis Observatory under the auspices of the Edinburgh Royal Society, and to the unique and valuable work that it has accomplished. Lord Lothian, in reply, admitted the very reasonable nature of the request, and he asked them to prepare a memorandum setting forth their views on the matter, which might be of service to him in approaching the Treasury on their behalf.

UNIVERSITY GRADUATION CEREMONIAL.

The Annual Graduation Ceremonial in the Faculties of Arts, Law, and Divinity took place on April 20th, when, after a number of honorary degrees had been conferred and the new graduates capped by the Vice-Chancellor, Professor Campbell Fraser delivered an address to the graduates on "Recent and Prospective Reform in the Faculty of Arts." His historical sketch of the progress of the University during the last quarter of a century was the tale of one who has studied and largely aided in the unfolding of each stage of the development that he now narrates. In looking to the future, he trusts that the proposed commission will inaugurate an epoch of still further development, and he indicated ways in which this might be aided, in an expansion of the Arts curriculum.

Edinburgh, April 26th.

DUBLIN.

(*From our own Correspondent.*)

DUBLIN HOSPITALS COMMISSION REPORT.

THIS report has at last become public, and is a voluminous one, extending to over fifty pages. It enters fully into the constitution and management of a large number of the Dublin hospitals. The annual Parliamentary grant amounts to £15,850, and of this £7600 is allocated to the Richmond Hospital. This sum was originally granted on the recommendation of a former commission, on account of its great educational advantages, and because a medical school was attached. The latter, however, has been removed, while other hospitals now provide students with means of clinical instruction. The Commissioners consider that there is great urgency for providing additional accommodation for the inmates of the North Dublin Union, and that in the event of their recommendation with reference to the future application of the Parliamentary grant being adopted, the Richmond, which would cease to be a State-supported institution, should be appropriated for the purposes of the Union. They consider Steevens' Hospital to be well managed, and the nursing arrangements to be exceptionally good. As regards the Meath Hospital, the power exercised by the physicians and surgeons to elect to vacancies on the staff was only conferred formerly on the medical staff in consideration of certain rights which were relinquished, and the hospital being a county infirmary, there should be no distinction made between it and other county infirmaries in this important particular of management. They also state that the grant of £600 was fixed by the Select Committee on the condition that it should be devoted to the support of fever beds; and on these grounds they recommend that the grant should be withdrawn. The report speaks of the world-wide reputation of the Rotundo Lying-in Hospital; but states that the subscriptions, which are chiefly from the Protestant portion of the community, might be capable of considerable expansion if a larger proportion of Roman Catholics were on the Board of Governors. They consider the limiting the master's tenure of office to seven years as radically bad; while they disapprove of the practice of exacting a fee from the assistant master, which obliges him to purchase his post. The charter of the Coombe Lying-in Hospital limits the governors to 21, and it appears that several members of the present board do not subscribe anything to the funds of the institution. Here, also, as in the Rotundo, the assistant masters pay the master for the appointment. There is only one assistant, the fact being, they assume, that there are very few willing to pay the fee which the master requires. The Commissioners do not think the grant will be continued to the Westmoreland Lock Hospital, and observe that there are but two ways in which it can be supported by private charity or local rates. They consider that the grant (£2500) to Cork-street Fever Hospital cannot be defended from the point of view from which the institution must be regarded ever since legislation has imposed upon local bodies the responsibility of providing against the spread of infectious disease. The Commissioners also consider that the grant to the Hospital for Incurables cannot be justified, as institutions of the kind have no claim for support at the hands of the general taxpayer. The purchase system for posts on the medical staff which exists in Jervis-street Hospital is condemned, and the nursing arrangements are not satisfactory. In Sir Patrick Dun's the arrangements for the isolation of fever cases are very imperfect, but the general state of the hospital is one of high efficiency. The purchase system which exists at the City of Dublin Hospital is referred to, while the nursing arrangements are stated to be admirable. In reference to Mercer's Hospital, the Commissioners state that the existing corporation has practically been confined to the medical staff, who seem to have regarded the lay governors as merely lay figures. As a result the purchase system in its worst possible form exists in this institution. The Commissioners do not consider in detail the voluminous evidence to which they were obliged to listen, because the replies which had been furnished to their queries had never been considered by the board, and were often upheld by one witness and contradicted by another; while, in the next place, the evidence as a whole presents such a melancholy picture of the relations subsisting between certain members of the medical staff, as well as of the internal organisation of the institution, that no good will result from making them more public than they have been made by the evidence itself. I hope on another occasion to refer to the conclusions of the Commissioners, and the various suggestions put forward by them in distributing the Parliamentary grant on more equitable principles than those at present adopted.

ROYAL COLLEGE OF SURGEONS.

As pointed out on a previous occasion, those candidates going in for the First Professional Examination next July have been very anxious to find out whether they will be classed for examination under the scheme which has up to this been in operation, or by the proposed conjoint scheme between the two Colleges. It is not altogether the subjects but the curriculum that has puzzled candidates, for under the conjoint scheme candidates require courses in practical chemistry, practical pharmacy, and materia medica, none of which are necessary under the ordinary scheme of the College. The Council have seen this difficulty, and last week passed a resolution recommending that students should be admitted to the First Professional Examination next July, on the present curriculum of the College. This must of necessity be ratified by the College of Physicians and the Managing Committee of the two Colleges, but it is expected that it will be carried out. I am informed that Mr. Austin Meldon will be a candidate for the vice-presidency of the College in June, 1888. Mr. C. H. Robinson, at present an examiner in materia medica, has intimated his intention of being a candidate for an examinership in anatomy at the annual election of examiners, which usually takes place on the first Monday in May.

BANQUET BY SIR WILLIAM STOKES.

The banquet given in celebration of Her Majesty's Jubilee, by the President of the Royal College of Surgeons in Ireland, on Saturday evening last, was in every way a decided success. About 120 gentlemen sat down to a sumptuous repast in the Albert Hall of the College, which was handsomely decorated with flags and flowers. The various toasts were given by Sir William Stokes with his usual eloquence and good taste, and all present were charmed with the manner in which he discharged the onerous duties appertaining to the position of host. The *ménu* cards contained a portrait of Her Majesty and the arms of the College, and were in every way appropriate to the occasion.

THE ROYAL UNIVERSITY.

A petition from the graduates and undergraduates to the Senate, to allow this year's Pass in honour of Her Majesty's Jubilee, will shortly be presented. It is, I believe, only intended for Arts students, and as the University of Dublin

Digitized by Google

has already granted this concession, it is felt that the Senate of the Royal University may very fittingly agree to the prayer of the memorialists. From the fifth report, which has just been presented to Parliament, I learn that during the past year the total number of persons who presented themselves for examination at the Royal University was 2933, or an increase of 43 over the previous year. Lady students obtained various distinctions, 9 taking degrees and 4 honours. The Senate draw attention to the subject of the maintenance of the buildings which have been partly purchased and partly erected by the State, and which they consider ought not to be chargeable from the endowments which are for certain academic purposes. Owing to failure of revenues, the "Dr. Hutchinson Stewart" Scholarships cannot be awarded this year.

ACADEMY OF MEDICINE IN IRELAND.

A meeting of the Fellows was held on Tuesday last, Dr. McDonnell in the chair. It was resolved, by a majority of fifty-four to three, that the title of the Academy should in future be "The Royal Irish Academy of Medicine"; and it was decided to present an address to Her Majesty congratulating her upon the celebration of her Jubilee.

FRACTURE OF THE SPINE.

At a meeting of the Surgical Section of the Academy of Medicine in Ireland last week, Mr. Edward Hamilton exhibited two cervical vertebræ which presented peculiar characters. A young man had fallen over a wall of about twelve feet into the soft mud of the river Liffey, and died twenty-one hours after removal to hospital. On post-mortem examination the fourth and fifth cervical spines were found fractured, and also the bodies of the same vertebræ in a vertical direction. That such extensive injuries should have occurred by a fall from such a trifling height on to soft, muddy ground appears unaccountable. At the same meeting Sir William Stokes showed a girl who had been operated on by lateral thryoidectomy.

Dublin, April 26th.

PARIS.

(From our own Correspondent.)

ANTIPYRIN AS AN ANODYNE.

AT a recent meeting of the Academy of Sciences, Professor Germain Sée made a communication upon "The Treatment of Pain by Antipyrin." This substance, which was discovered by Knorr in 1884, was first employed, as its name implies, for lowering the temperature, and it was expected that it would prove useful in typhoid fever, articular rheumatism, and other acute affections. It has not, however, been as satisfactory in its action as was anticipated, and if the temperature can be by its use lowered at will, it does not seem to exercise much effect upon the process of disease. But according to M. Germain Sée, antipyrin is the remedy, *par excellence*, for pain, and far superior in every way to antifebrine. In fifteen cases of subacute rheumatism, or hydrarthrosis, treated unsuccessfully by salicylate of soda and ignipuncture, the pain and swelling disappeared in a few days, and, the medicine being continued, there was no relapse. The same effect was observed in cases of acute gout, both primary and secondary to chronic gout with chalky deposits. Antipyrin, to the extent of from 60 grs. to 90 grs. a day, removed both pain and swelling in from two to four days without any bad effect either on the heart or kidneys. But it is, above all, in nervous pain that its action is most remarkable. A first group comprises four cases of facial neuralgia, one of which was inveterate, six of migraine, with one failure, and four headaches. In a second series are classed five cases of sciatica, one of simple neuritis, two of diabetic neuritis, and two of neuritis with zona (one failure). Cases of lumbago and muscular rheumatism make up a total of eighteen. The third category relates to five cases of locomotor ataxia, in four of which the pains were removed by antipyrin. In the fifth instance it failed, as did also antifebrine. The last group comprehends those affections of the heart, aorta, and coronary arteries in which angina is a most painful symptom. In six patients with cardio-aortic disease, and in three others with aneurysm, the painful manifestations disappeared entirely, without any evil effect being caused by the medicine on the strength or regularity of the cardiac pulsations. The dose given by M. Sée is from three to six grammes daily. If too much is given at one time, nausea and giddiness may supervene, but when the whole amount is divided into small repeated doses of half a gramme, no disagreeable effects are observed. Antipyrin may be given and continued for a length of time with but little risk. Antifebrine, on the other hand, is dangerous when administered in doses exceeding one gramme. It causes hæmoglobin to pass into the condition known as metahæmoglobin, and the blood losing part of its oxygen becomes of a chocolate colour, cyanosis and collapse being the consequences. From laboratory experiments it is found that reflex excitability to electricity is diminished by antipyrin, and the sensory perceptivity of the cord is lessened.

TREATMENT OF DIABETES.

A few weeks back M. Martineau created a sensation in the medical world by the publication of the results obtained by him with his "specific" for diabetes, and since then we have all been prescribing arsenicated lithia water. Dr. Le Blond now makes known a rival treatment, which, if not precisely new, is novel in its mode of application, and from which he has obtained some remarkable results. The administration of oxygen in the form of peroxide of hydrogen has often been tried, but, although it would seem theoretically to be the ideal treatment for glycosuria, results have not been sufficiently constant to popularise it. M. Le Blond has reopened the question, and advises the administration of an aerated water which has been manufactured in Paris for the last few years, and which only differs from the familiar *siphon* in that it is gaseous from oxygen instead of carbonic acid. Three cases are reported, in which the treatment caused the total disappearance of sugar from the urine; in a fourth the partial failure was due to imperfect oxidation from chronic bronchial catarrh.

M. PASTEUR'S TREATMENT.

M. Pasteur has returned to Paris in good health, and was warmly welcomed by his colleagues at the last meeting of the Academy of Sciences. On this occasion a communication was made concerning two stablemen in the employ of M. Charles de Lesseps, one of whom had been licked by a mad dog, and cured by anti-rabic inoculation. His fellow-servant was bitten, and having neglected this precaution, died of rabies. In my account of the case of Hamyan the dose of pilocarpine given daily is reported to be fifteen grains. This is a misprint for one-fifth of a grain.

MORPHINOMANIA IN MONKEYS.

Experiments have hitherto tended to show that animals did not acquire the so-called morphia habit. Rabbits to which morphia is administered for months in enormous doses, as much as eight grains per day, bear the sudden suppression without any evidence of discomfort. But it would appear from a memoir sent by Dr. Jammes of Cambodge to the Academy of Sciences that this is not the case with monkeys. When these live with opium-smokers, and have become accustomed to a medicated atmosphere, they acquire a taste for the poison. One monkey, for instance, would wait until its master had laid aside his pipe, and would then take it up and smoke what remained. If not allowed to do so for several days, it would fall into a state of depression and stupor, which disappeared as soon as the stimulant was supplied. I dare say some of your readers will remember a monkey at the Zoological Gardens which had been taught by the keeper to smoke tobacco.

TREATMENT OF GRAVE EPISTAXIS.

M. Verneuil, who, although one of our most eminent surgeons, makes frequent incursions into the domain of pure medicine, read a communication at the Academy of Medicine upon the treatment of certain forms of epistaxis by counter-irritation over the region of the liver. M. Verneuil began by stating that he had at first thought that the method was entirely his own, but from bibliographical research it turned out that he had been anticipated to a certain extent by Galen, who says that large cupping glasses applied to the hypochondria arrest nasal hæmorrhage. In the first case related by M. Verneuil, the epistaxis was probably symptomatic of cirrhosis of the liver. Quinine, ergotine, and digitalis had all been tried in vain. The hæmorrhage continued to recur at intervals. The second patient had suffered from nasal hæmorrhage, which seemed to have been caused by the shock of a kick from a horse. In this

Digitized by Google

case plugging had failed. The third was the subject of chronic nephritis, with secondary affections of the heart and liver, and the cavity of the nose had been plugged without effect both with ergotine and perchloride of iron. M. Vernenil's treatment, which was immediately and permanently efficacious, consisted of the application over the region of the liver of a large blister.

Paris, April 27th.

ROYAL COLLEGE OF PHYSICIANS.

A COMITIA of the College was held on Thursday last, the 28th inst., the President, Sir W. Jenner, Bart., in the chair. The chief business was the election of new Fellows. The following were chosen:—George Oliver, M.D. Lond., Harrogate; Robert Cory, M.D. Cantab., Lambeth Palace-road, S.E.; Henry Radcliffe Crocker, M.D. Lond., Welbeck-street, W.; Frank Buszard, M.D. Lond., Northampton; Robert Saundby, M.D. Edin., Birmingham; Charles James Cullingworth, M.D. Durh., Manchester; Wm. Julius Mickle, M.D. Toronto, Bow, E; George Allan Heron, M.D. Glasgow, Harley-street, W.; James Anderson, M.D Aberdeen, Wimpole-street, W.

There were also admitted as Members—D. Burgess, M.B., Jas. Calvert, M.D., Thos. Johnstone, M.D., and T. F. Pearse, M.D.

Licences were granted to the ninety-two candidates who had passed the recent examination.

Communications were read from students of the Westminster Hospital, of Charing-cross Hospital, and the London Hospital, containing resolutions in support of the granting of degrees by the Royal Colleges. These were referred to the Committee of Delegates.

The text of the address to Her Majesty on the occasion of her Jubilee was read and approved.

The Quarterly Finance Committee submitted their report, which contained a recommendation that the stipend of the Registrar be raised to the sum of 500 guineas. The proposal, moved by Sir E. Sieveking, seconded by Dr. Hare, and supported by Dr. Quain and the President, was received with much applause; and the President expressed the sense of the College in stating that neither money nor thanks could repay the debt which the College owes to Sir Henry Pitman. Sir Henry acknowledged the vote in feeling terms, and took occasion to present the College with a volume which he had compiled, to replace the only volume of the College annals (viz., 1771 to 1781) that is missing from the long series.

Obituary.

ALFRED MEADOWS, M.D., F.R.C.P.

WE briefly adverted last week to the death of this well-known obstetrician, which took place at the early age of fifty-five, after a short illness. A familiar figure will be missing from our midst. A name which designated a physician especially esteemed by the public drops from the roll of contemporary practitioners.

Dr. Meadows was born at Ipswich, and received his medical education in King's College, London, where his energy and zeal in the study of his profession were early recognised. He speedily took an advanced place amongst the students of his year, and filled the office of resident obstetrician at the hospital with distinction. He early showed considerable literary ability, and as a student edited the Transactions of the King's College Medical Society. He took the M.B. Lond. in 1857, the M.D. in 1858, and became F.R.C.P. in 1873. The appointments which he held at various periods of his career were numerous, including that of physician-accoucheur to the St. George's and St. James's Dispensary, assistant-physician for diseases of women and children at King's College, physician to the Hospital for Women, Soho-square, and physician-accoucheur to the General Lying-in Hospital. At the time of his decease he held the appointment of physician-accoucheur to St. Mary's Hospital, an office to which he had been elected without competition on the resignation of the late Dr. Tyler Smith. His death has occasioned a profound feeling of regret amongst his colleagues at the hospital, who fully appreciated his ability, and have received a great shock from his sudden and untimely end. Besides being an honorary member of numerous foreign societies, Dr. Meadows obtained a Commandership in the Order of Wasa of Sweden, and in his own country was made a justice of the peace for the county in which he possessed a country house—Poyle Manor, Colnbrook, Bucks.

Dr. Meadows was distinctly a man of exceptional ability. Not only did he achieve a great success in the department of practice which he had chosen whilst yet a student, but in various directions he evinced power of no ordinary kind. Early in his career he published a "Manual of Midwifery," which has been widely read. This was followed by the "Prescriber's Pharmacopœia," a pocket companion of a handy kind. About the year 1860 or 1861 he commenced to edit a monthly journal of medicine called the *London Medical Review*, which enjoyed a considerable success for a few years. It was characterised by a great spirit of fairness, and the articles, which were contributed by many old friends and fellow-students of the editor, were in advance of the more usual examples of critical composition.

Besides enjoying a lucrative practice, Dr. Meadows was also, at least in the more recent part of his career, possessed of good private means. This circumstance, far from interfering with his energy, appeared to intensify his zeal for the profession to which he was passionately attached. With a strong religious bias, he lost no opportunity of endeavouring to forward the interests of the Guild of St. Luke, in the formation of which he took the most prominent part. Dr. Meadows was also well known as an energetic Freemason. He was a past officer of the Grand Lodge of England, and was connected with several private lodges. He took one of the most active parts in founding the University of London Lodge, and it was largely due to his influence that so many members of our profession joined it. After serving in the Wardens' chairs he became the Master of the Lodge, which post he held at the time of his death. At his country house he showed great artistic taste in the decorations and furniture, whilst the completeness which distinguished all his arrangements for comfort and elegance proved the untiring energy which he was accustomed to throw into every subject which engaged his attention.

Dr. Meadows had a good address. He was of kindly nature, hospitable, strongly Conservative in politics, and much attached to his patients. He was a good operator and an ingenious mechanician. Unlike so many members of his profession he was an excellent man of business, and as chairman of a meeting he was unsurpassed by any of his contemporaries in our ranks.

Dr. Meadows leaves a widow and a daughter. He was buried on Saturday last at Colnbrook, his funeral being attended by a very large concourse of friends.

CHARLES JAMES BRACEY, M.B.

WE record with regret the decease of Mr. C. J. Bracey, of Birmingham, which occurred on April 21st at the residence of a relative near London, in the forty-ninth year of his age. Mr. Bracey was the son of an esteemed Birmingham surgeon. He pursued his studies at the Queen's College and General Hospital, Birmingham, and subsequently at King's College, London, and in Paris. He took the M.B. of the London University in 1861, and carried off the University Exhibition and Gold Medal in Surgery, taking in addition high honours in Medicine and Midwifery. Returning to Birmingham, he was medical tutor at the school for two years, and afterwards house-surgeon at the General Hospital. He subsequently became Professor of Anatomy in Queen's College, surgeon to the Children's Hospital, and surgeon to the Hospital for Women. At this time no surgeon in Birmingham stood so well for attaining the first position as a consultant, for which by education, by experience, and by address Mr. Bracey was so eminently fitted. But the state of his health, never very robust, warned him about ten years ago that he must give up public work and the anxieties and responsibilities of operative and consulting practice. Mr. Bracey then devoted himself to his practice, which was of the highest class, and even then he had to recuperate by rest and frequent sea voyages.

The deceased gentleman had for the last eighteen months suffered from retention of urine, due to prostatic disease, and a few weeks ago he decided to go up to London to place himself under the care of his friend Mr. Page of

Digitized by Google

Mary's Hospital, who successfully removed a large mber of prostatic calculi. The operation was most isfactory, and for three weeks he seemed to go on ourably, and, the wound having healed, he was removed m town and went to stay at the residence of a relative paratory to taking a voyage to the Canary Islands. He, wever, suffered from increasing vomiting, which had been re or less troublesome since the operation, and sank from haustion nearly a month after its performance.

The charm of Mr. Bracey's disposition and manner, the lture of his mind, and the tenderness of his heart will long held in loving memory by the circle of friends o knew him intimately—a circle limited by the require- nts of his health only, for no professional man in rmingham would have been more welcomed by every se. By his professional brethren and by his patients he s held in the deepest respect and closest affection, and s early death has caused a blank in the profession in rmingham.

THE CHEVALIER FELICE GALLONE.

THE Royal Household of Italy has just lost an old and usted medical adviser in Dr. Gallone, who died in Rome April 21st, in his seventy-third year. He qualified in the Summi in Medicinâ Honores" in the University of Turin, d at once devoted himself to the practice of his profes- on. In 1854, when the cholera epidemic was numbering any victims in the sub-Alpine capital, he exerted himself ith so much courage, skill, and success, that the then King ictor Emanuel decorated him with the Cross of SS. Maurice d Lazarus, while he also received the gold medal for good service in the cause of public health." Following e Royal household to Rome in 1870, he there continued e practice of his profession, winning the esteem of all his lleagues and earning the gratitude of the august *clientèle* which his official connexion with the Court introduced him.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF DINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS F GLASGOW.—At the April sittings of the examiners, held Glasgow, the following candidates passed the final examination for the triple qualification:—

Adie, Alfred A., Glasgow.
Brodie, James, Edinburgh.
Bowker, C. S., Appleby Magna.
Clark, George A., Southsea.
Cooper, W. F., Birmingham.
Davis, George W., Liverpool.
Huntley, Edith Ara, St. Albans.
Kapadia, S. A., London.
M'Lean, Alfred Jos., St. Helens.
Marquis, A. F. C., Glasgow.
Rutherford, V. H., Newcastle-on-Tyne.
Smith, Henry, Glasgow.
Williams, W. A. G., Carmarthen.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on April 21st:—

Hensley, Arthur Egerton, Parkham Rectory, Bideford.
Harris-Liston, Llewellyn, Cambridge House, St. John's.

On the same day eleven others were admitted to examination, of whom three passed in Surgery and seven passed as Assistants.

THE Prince of Wales has intimated his intention of visiting Great Yarmouth on the 18th prox., when the foundation stone of a new hospital is to be laid.

THE annual Hospital Sunday demonstration of the Grantham Friendly and Trade Societies has been fixed for the 15th prox.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Dr. Charles Mercier has been appointed to give a course of lectures on "Neurology and Alienism" at this medical school in the winter session.

THE foundation stone of the Merthyr Tydvil General Hospital is to be laid on June 21st, and the Marquis of Bute will be invited to perform the ceremony.

AT the last meeting of the Hospitals Committee of the Manchester City Council, it was resolved to accept a tender for the erection of an infectious diseases hospital for the sum of £13,937.

PRESENTATION.—On the 16th inst. Mr. J. F. Little was presented with an illuminated address and an oak casket on the occasion of his leaving Ilkley for the south of England.

THE City Council of Worcester have adopted, by 30 to 8 votes, a scheme of sewage disposal by means of precipitation works at Digles, prepared by Mr. Thomas Hawkesley. The estimated cost is about £40,000.

LEGACIES AND DONATIONS.—A legacy of £50, bequeathed by the late Mr. Joseph Borman, has been received by the treasurer of the Lincoln County Hospital.—The late Mr. Benjamin Lancaster of Bournemouth, who died on the 16th ult., has bequeathed £1000 each to St. George's Hospital and the Brompton Cancer Hospital, and £500 each to the Middlesex Hospital, King's College Hospital, the Consumption Hospital, Brompton, and the Hospital for Incurables, Putney.—Mr. R. A. Newbon of Islington has given £1050 to the Great Northern Central Hospital, with the object of endowing a bed in the new establishment. In order to complete the building a sum of £45,000 is required; only £10,000 has as yet been subscribed.

AT a meeting of the subscribers to the Dartmouth Jubilee Cottage Hospital scheme on the 22nd inst., regret was expressed at the smallness of the support afforded to the project, but it was ultimately agreed to hire a building and commence operations, the expenses of the hospital being limited to £150 annually.

THE ABUSE OF MEDICAL CHARITIES.—The Glasgow Medical Charities Committee, appointed at the public meeting of practitioners in the Faculty Hall on the 30th ult., met on Friday, the 22nd inst., and, having appointed Professor James Morton, M.D., chairman, and Dr. Edward McMillan vice-chairman, and the other office-bearers and members of the executive, proceeded to consider the initial steps of dealing with the whole question of the abuse of medical charities. Professor Gairdner strongly advised a conference with the Charity Organisation Society, as being in possession of the best possible information regarding the abuse of charitable institutions and the most successful means of dealing with it. He was of opinion that while the out-door cases should be seen for the first time, the services of that Society might be obtained for the purposes of investigation. Dr. Erskine spoke of the importance of introducing the lay element into the committee, and it was proposed to invite the managers of the various medical charities to confer with the committee and become members of it. Other important points were afterwards considered. The Secretary (Dr. Robb, Carlton-place), who was desired to obtain information from other towns in England and Scotland where reform of charitable medical institutions has been effected or is under consideration, will, we understand, thankfully acknowledge all such which may be addressed to him.

THE LEVÉE.—The following members of the medical profession were presented to the Prince of Wales at a *levée* held on the 25th inst. at St. James's Palace by His Royal Highness on behalf of Her Majesty:—Surgeon-Major W. R. Brunton, 1st Surrey Rifles; Dr. T. Vincent Dickinson; Dr. James Ellison, surgeon to Her Majesty's Household at Windsor; Surgeon Alfred Thomas Irvine Lilly, Army Medical Staff; Dr. David Nicolson, superintendent of the State Asylum, Broadmoor; Dr. C. V. Stanford; Sir James Sawyer; Surgeon W. Henderson Starr, Army Medical Staff; Surgeon Walter Tytheridge, 12th Middlesex (Civil Service) R.V. Also the following members of the Naval Medical Service:—Surgeon J. E. Coad, M.B.; Surgeon W. J. Colborne; Surgeon G. F. Collins; Surgeon G. T. Collingwood; Surgeon C. Dickinson; Surgeon E. Griffin, M.D.; Surgeon H. St. D. Griffiths; Surgeon R. Hardie, M.B.; Surgeon J. D. Hughes; Surgeon H. Holyoake; Surgeon J. A. Moon; Surgeon J. D. Menzies, M.B.; Surgeon R. Miller, M.B.; Surgeon J. Moore; Surgeon Charles Strickland; and Surgeon J. W. O. Underhill, M.B. The following members of the medical profession also attended:—Drs. James H. Aveling, Argyll-Robinson, T. B. Christie, C.I.E., Grainger Stewart, C. A. L. Robertson, J. Wickham Legg, D. F. Phillips, P. Heron Watson, and Messrs. Berton (Acting Surgeon) and T. J. Haran (Inspector-General, R.N.). [The above list, though carefully compiled, may possibly not be quite complete. Any names which may have been inadvertently omitted will, however, be published in our next, if intimation be given to us to that effect.]

Digitized by Google

THE Prince and Princess of Wales will open the new buildings of the London Hospital at 5 o'clock on the 21st prox.

UNIVERSITY COLLEGE HOSPITAL.—A public dinner in aid of the funds of this charity was held on Wednesday last, the Right Hon. G. J. Goschen, M.P., in the chair. After the usual loyal toasts had been honoured, Mr. B. L. Cohen proposed "The Houses of Parliament," and Mr. R. G. Webster, M.P., responded. Mr. Goschen, in proposing the toast of the evening, was very happy in his comparison between the nation and the institution; both alike had debts and liabilities, and an inelastic revenue. Dr. Russell Reynolds proposed "The Hospital and Medical Committees," which was replied to by Captain Douglas Galton and Dr. G. V. Poore. The dinner was successful, £1885 having been announced by Mr. N. H. Nixon, the secretary, as the amount of subscriptions.

UNIVERSITY OF OXFORD.—The following notice to candidates intending to offer themselves for either of the examinations for the degree of Bachelor of Medicine has just been issued by the Regius Professor of Medicine, Sir Henry W. Acland:—(1) The Final Examination to be holden in Trinity Term next will by statute, and under the Medical Act, 1886, be an examination qualifying successful candidates, first, for the degrees of Bachelor in Medicine and of Bachelor in Surgery; and, secondly, for the registering of a complete qualification in Medicine, in Surgery, and in Midwifery. (2) That the Final Examination for the degrees of Bachelor of Medicine and Bachelor of Surgery will begin in the first week of Trinity Term—i.e., on Tuesday, May 31st. (3) That an examination for the degree of Master in Surgery will be holden during the same week. (4) That the First Examination for the degree of M.B. will begin at a later date during the Trinity Term—viz., on Monday, June 27th. Also the Secretary to the Boards of Faculties has given notice that, in accordance with the statute, names of candidates for the Second or Final Examination for the degree of Bachelor of Medicine must be sent in to him not later than May 14th; and for the First Examination for the same degree not later than June 11th. All candidates, in giving in their names, are required by the statute to pay the fees for admission and to produce the required certificates.

MEDICAL NOTES IN PARLIAMENT.

The Pasteur Treatment.

IN the House of Commons on the 25th inst., Mr. W. M'Laren asked the Secretary of State for the Home Department whether it was a fact that a constable of the Nottinghamshire police, and two constables of the metropolitan police, were sent to M. Pasteur for treatment last year; whether any of them were sent at the public expense; whether, considering the number of deaths that had attended M. Pasteur's treatment, he would use his influence to prevent any more public servants being subjected to it, or public money being spent upon it, until the Buisson Vapour Bath system, which could be obtained in England, had been thoroughly investigated; and whether, as a Committee had been appointed to investigate M. Pasteur's system, he would appoint another Committee to investigate the Buisson Vapour Bath system of preventing hydrophobia.—Mr. Ritchie, in reply, said that the Nottingham constable was sent at the cost of the county rates, and the metropolitan police at a cost to the public of £227. The report of the Committee appointed to inquire into the Pasteur system had not yet been received. It was not proposed to ask the Committee to extend the inquiry to the Buisson system, or to appoint another Committee of Inquiry.

Aberdeen Infirmary and Lunatic Asylum Bill.

On the 27th inst. this Bill was considered and ordered for third reading.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARMSON, FRANK GREASLEY, M.R.C.S., L.S.A., has been appointed Medical Officer and Public Vaccinator to the Yoxall District of the Lichfield Union, vice George Chapman, M.R.C.S., L.S.A., resigned.

BARLING, A. S., L.R.C.P.Lond., M.R.C.S., has been appointed House-Physician to the General Infirmary, Leeds.

CAREY, BASIL DE B., B.A.Cantab., M.R.C.S., L.S.A., has been appointed Clinical Assistant to the Hospital for Consumption and Diseases of the Chest, Brompton.

CARTER, D'ARCY B., M.R.C.S., L.R.C.P., has been appointed Surgeon to the Shipley and Eccleshill District of the Great Northern Railway.

DONALDSON, DAVID GILBERT, M.B., C.M.Ed., has been appointed Parochial Medical Officer and Medical Officer of Health for Dunning, Perthshire.

ELLIS, WILLIAM HENRY, M.R.C.S., L.S.A., has been appointed Surgeon to the Shipley and Eccleshill District of the Great Northern Railway.

FORSYTH, ROBERT, M.D.Glas., has been reappointed Medical Officer of Health for the Birstal Urban District.

FOX, GEORGE MARTIN, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Resident Medical Assistant to the General Hospital, Birmingham.

GRIMSDALE, THOMAS BABINGTON, B.A., M.B.Cantab., M.R.C.S., has been elected Honorary Assistant Medical Officer to the Shaw-street Hospital for Women, Liverpool.

HOLLOWAY, WILLIAM G., B.A., M.B., M.R.C.S., has been appointed House-Surgeon to the Hastings, St. Leonards, and East Sussex Hospital.

JONES, JOHN J., M.B., C.M.Glas., has been appointed Medical Officer for the Laughton District of the Rotherham Union.

LILLEY, JAMES HARRIS, M.A., M.B. Cantab., M.R.C.S., has been appointed Medical Officer for the Burghill District of the Hereford Union.

MACPHERSON, ALEXANDER, M.D.Aber., has been appointed Medical Officer of Health for Haslingden, Lancashire.

MILNER, E. T., M.A., M.B.Oxon., has been appointed Resident Medical Officer at the Convalescent Hospital in connexion with the Manchester Royal Infirmary.

NEVINS, ARTHUR E., M.R.C.S., L.R.C.P.Ed., has been appointed House-Physician to the Middlesex Hospital, vice Hedley Bartlett, L.R.C.P., M.R.C.S.

OLDHAM, MONTAGUE WILLIAMS, M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Ophthalmic and Obstetric House-Surgeon to the Queen's Hospital, Birmingham, vice T. Emery, resigned.

SMART, DAVID, M.B., C.M.Ed., B.Sc., has been elected Honorary Assistant Medical Officer to the Shaw-street Hospital for Women, Liverpool.

TOMLINSON, W. H., M.R.C.S., L.S.A., has been appointed House-Surgeon to the Oldham Infirmary.

WILLIAMS, LIONEL, M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to the York County Asylum.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

CANCER HOSPITAL, Brompton, S.W. — Assistant House-Surgeon. Appointment for six months. Salary at the rate of £35 per annum, with board and residence.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C. — House-Surgeon. Rooms, gas, and firing.—Assistant Surgeon.

CHELTENHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Salary £40 per annum, with board and apartments.

CITY OF LONDON LUNATIC ASYLUM, Stone, near Dartford, Kent.—Medical Superintendent. Salary £500 per annum, with residence, coals, gas, washing, and garden produce.

COUNTY ASYLUM, Stafford.—Resident Medical Officer and Superintendent. Salary £500 per annum, with unfurnished residence within the Asylum, and £200 in lieu of board.

DORSET COUNTY ASYLUM, near Dorchester.—Assistant Medical Officer. Salary £120 per annum, with board &c.

FARRINGDON GENERAL DISPENSARY AND LYING-IN CHARITY, Bartlett's-buildings, Holborn, E.C.—Honorary Physician.

GLOUCESTER GENERAL INFIRMARY AND GLOUCESTER EYE INSTITUTION.—House-Surgeon. Salary £100 per annum, with board, lodging, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, N. — House-Physician.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST AND THROAT, Margaret-street, Cavendish-square, W. — Honorary Visiting Physician.

LONDON THROAT HOSPITAL, Great Portland-street, W.—Dentist.

MADAGASCAR MEDICAL MISSION. — Superintendent of Hospital, &c. Salary £150 to £200 a year, house, outfit, &c.

MASON SCIENCE COLLEGE, Birmingham.—Professor of Physiology.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury. — Senior House-Physician. Salary £100 per annum. Junior House-Physician. Salary £50 per annum. In each case board and apartments are supplied in the hospital.

ROYAL ALBERT HOSPITAL, Devonport. — Assistant House-Surgeon. Board and lodging in the hospital, but no salary.

SUSSEX COUNTY HOSPITAL, Brighton.—Assistant Surgeon. Assistant House-Surgeon. Board, lodging, and washing, but no salary.

YORK FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Assistant Medical Officer. Salary £150 per annum; part accouchement fees; £20 for cab hire.

Births, Marriages, and Deaths.

BIRTHS.

ACKLAND.—On the 20th inst., at Bideford, Devon, the wife of Charles Kingsley Ackland, L.R.C.P.Lond., of a daughter.

BERRY.—On the 21st inst., at Horncastle, the wife of J. B. Berry, M.R.C.S., of a daughter.

CARTER.—On the 21st inst., at Stamford, the wife of T. E. Carter, M.B.Lond., of a daughter.

DUKE.—On the 15th inst., the wife of Maurice Smelt Duke, M.R.C.S., of Kennington-park-road, London, of a son.

FAIRBANK.—On the 26th inst., at Moulsey House, Windsor, the wife of William Fairbank, M.R.C.S.Eng., of a daughter.

FLECK.—On the 26th inst., at Frogmoor Lodge, High Wycombe, the wife of William Fleck, M.D., of a son.

GODDARD.—On the 25th inst., at Wembley, near Harrow, the wife of Charles Ernest Goddard, M.R.C.S., L.R.C.P., of a son.

JONES.—On the 19th inst., at Marylands-road, W., the wife of J. Thoresby Jones, L.R.C.P., M.R.C.S., of a son.

MCCLEMENT.—On the 19th inst., at Holles-street, Merrion-square, Dublin, the wife of F. McClement, M.D., Staff Surgeon, H.M.S. *Active*, of a son.

MCMULLEN.—On the 14th inst., at Brixton-road, the wife of W. McMullen, L.K.Q.C.P.I., L.R.C.S.I., of a daughter.

SCOTT.—On the 14th inst., the wife of Alfred Scott, M.R.C.S., German-place, Brighton, of a daughter.

SCOTT.—On the 21st inst., at Bladud-buildings, Bath, the wife of Richard J. H. Scott, M.R.C.S., of a son.

SMITH.—On the 23rd inst., at St. Austell, the wife of J. Snowden Smith, M.R.C.S., L.R.C.P., of a son.

SYDNEY.—On the 25th inst., at Pownall-gardens, Hounslow, the wife of Henry Sydney, M.D., of a son.

MARRIAGES.

ARNOLD—MUNN.—On Feb. 16th, at the Cathedral, Shanghai, Charles Arthur Arnold, M.B., C.S.Aber., of Nagasaki, Japan, to Mary Isabella, only daughter of the late Captain H. O. Munn, 7th Royal Fusiliers.

BRODIE—PETTIGREW.—On the 19th inst., at 17, Queen's-crescent, by the Rev. John Isda'e, assisted by the Rev. James Douglas, M.A., John Ewan Brodie, M.D., to Mary Stuart, daughter of Matthew Pettigrew.

CHURCHOUSE—KING.—At East Haddon, Wm. Jno. Franklin Churchouse, L.R.C.P.Ed., to Kate Emma, second daughter of George King, Esq., of East Haddon, Northamptonshire.

COURTENAY—AP-JOHN.—On the 20th inst., at St. Philip's Church, Kensington, W., Edward Maziere Courtenay, M.B., Limerick Asylum, to Alice, widow of the late George Atkins, Barrister-at-law, and youngest daughter of the late Rev. M. Lloyd Ap-John, of Linfield, and Rector of Ballybrood, co. Limerick, Ireland.

DAVIES—MCLAREN.—On Feb. 22nd, at All Saints' Church, Dunedin, N.Z., John Morgan Lloyd Davies, M.R.C.S., to Jessie Maud, third daughter of Robert McLaren, Esq., of Dunedin.

FOTHERGILL—WEATHERELL.—On the 21st inst., at the Parish Church of Elton, Notts, Thomas Prince Fothergill, M.D., to Eleanor Jane (Nora), eldest daughter of the late Robert Weatherell, Rector of Elton.

MACPHERSON—TAYLOR.—On the 20th inst., at St. Chrysostom's Church, Everton, Francis Alexander Macpherson, L.R.C.P. and L.R.C.S.E., to Florence, elder daughter of the Rev. W. F. Taylor, D.D., Vicar, Hon. Canon of Liverpool, and Rural Dean of Walton.

PATON—AUSTIN.—On the 27th inst., at 7, Moray-place, Edinburgh, by the Rev. John Stuart, D.D., Frederick Erskine Paton, M.B., C.M., of Abergavenny, Monmouthshire, to Maggie, eldest daughter of the late Rev. John Mein Austin.

POWELL—SANDERS.—On the 20th inst., at Christ Church, Lee, by the Rev. Arthur Stevens, brother-in-law of the bride, assisted by the Rev. L. A. Smith, Vicar, Lewis B. Powell, M.R.C.S.Eng., to Edith, youngest daughter of the late Thomas Sanders, of Wheatley, Oxon.

WOODS—HEATLEY.—On the 20th inst., at St. Andrew's, S.W., Frank Woods, L.R.C.P. Lond., M.R.C.S., L.S.A., to Eva Carlota, youngest daughter of the late John D. Heatley, of Higham Hill, Walthamstow.

DEATHS.

CHATTO.—On the 19th inst., at Chapel-road, Notting-hill, John Chatto, M.R.C.S., Librarian to the Royal College of Surgeons of England, aged 77.

CROFTS.—On the 25th inst., at Church Gresley, near Burton-on-Trent, William Carrick Crofts, M.R.C.S.E., &c., aged 52. No cards.

GUTHRIE.—On the 18th inst., at Brechin, N.B., John Guthrie, M.D., in his 57th year.

HALKET.—On the 17th inst., at sea, on his homeward voyage from Australia, Laurence John Halket, L.R.C.P.Lond., third son of the late David Halket, of Newcastle-on-Tyne, formerly of Perth and London. Australian papers please copy.

HINGESTON.—On the 25th inst., at Lyme Regis, William Hingeston, M.R.C.S.

ILIFF.—On the 25th inst., at Kennington-park-road, S.E., William Tiffin Iliff, M.D. Lond., Medical Officer of Health for St. Mary, Newington, aged 63.

PATER.—On the 24th inst., at Oxford-terrace, Hyde-park, William Thompson Pater, M.R.C.S., late Medical Superintendent of the County Asylum, Stafford, aged 52.

TREVOR.—On the 25th inst., at Beaumaris, N. Wales, Arthur Tudor Humphreys Trevor, M.R.C.S., L.R.C.P.Lond., formerly of Iquique, West Coast of S. America, aged 42.

VARENNE.—On the 22nd inst., at Kelvedon, Essex, Ezekiel George Varenne, M.R.C.S., aged 75.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, May 2.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL INSTITUTION.—1.30 P.M. Annual Meeting.

SOCIETY OF ARTS.—8 P.M. Mr. J. M. Thomson: The Chemistry of Substances taking part in Putrefaction and Antisepsis.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Mr. F. Henri Weiss: On the Destruction of a Permanent Tooth Pulp by an Alveolar Abscess attached to a Deciduous Molar.—Dr. St. George Elliott will show a New Hot-air Motor.—Mr. E. Lloyd Williams will exhibit a Hot-air Syringe.—A paper by Mr. Humphreys.—Mr. W. Hern: Cocaine as a Local Anæsthetic in Dental Surgery.—Dr. Geo. Cunningham: The Physiological Action of Cocaine.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Sir William Mac Cormac will deliver the Annual Oration, after which the President will hold a Reception, and a Conversazione will follow. The String Band of the Royal Artillery will be in attendance.

Tuesday, May 3.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

ROYAL INSTITUTION.—3 P.M. Prof. W. E. Ayrton: Electricity.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Report of Morbid Growths Committee on Dr. Edmunds' Specimen of Horny Papilloma of Hand.—Mr. Hutchinson: Destructive Arthritis of Knee without Suppuration.—Mr. T. Smith: Senile Arthritis.—Mr. Hutchinson, jun.: Sarcoma (?) of Knee.—Dr. Pitt: Carcinoma of Spine and Liver.—Dr. Coupland and Dr. Pasteur: Diffuse Sarcoma of Spinal Pia Mater (two cases).—Dr. Maguire: Interstitial Aneurysm of Inter-auricular Septum.—Mr. R. W. Parker: Cases of Sarcoma in Children.—Mr. Lawson Tait: Tubal Pregnancy.—Dr. Payne: Multiple Neuro-fibromata in connexion with Molluscum Fibrosum.—Mr. Leopold Hudson: Tumour of Prostate. Card Specimens:—Mr. Fenwick: Urinary Tuberculosis with Multiple Calculi.—Dr. Barlow: Renal Sarcoma in a Child.—Mr. Page (for Mr. Raven): Sarcoma of Dorsal Vertebræ.—Mr. Shattock: Tubercular Arthritis (six cases).

Wednesday, May 4.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M. Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M. Saturday, same hour.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. Doran, Dr. John Phillips, Mr. Barton, Mr. Lawson Tait, and others.—Dr. Matthews Duncan: Hæmorrhagic Parametritis.—Dr. Lewers: On the Frequency of Pathological Conditions of the Fallopian Tubes as determined by Post-mortem Observations at the London Hospital.

Thursday, May 5.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The Chemistry of the Organic World.

HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. Hugh Owen Thomas: The Physical Signs of Disease and Recovery of the Hip-joint, with a Demonstration of the Mechanical Fixation of the Joint.—Dr. Stephen Mackenzie: Some cases of Hysteria.—Mr. A. Q. Silcock: A fatal case of Hysteria.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Living and Card Specimens at 8 P.M. Messrs. Critchett and Juler: (1) Guttate appearance of Fundus; (2) Peculiar Pigmentary Degeneration of Choroid.—Mr. Ernest Clarke: Improved Artificial Eyes. Papers:—Mr. W. Lang: (1) A fatal case of Meningitis after Excision of a Suppurating Globe; (2) On the Insertion of Glass Globes into Tenon's Capsule after Excision of the Eyeball.—Mr. Nettleship: (1) Three cases of Night-blindness, with peculiar Retinal Changes; (2) Two cases of Quinine Amblyopia.—Dr. Brailey: Recurrent Choroido-retinitis in region of Macula, probably an early stage of "central guttate choroiditis."—Mr. Mackinlay: Complete Self-enucleation of Eyeball.

Friday, May 6.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—9 P.M. Dr. Brunton: The Element of Truth in Popular Beliefs.

Saturday, May 7.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. R. Von Lendenfeld: Recent Researches on Sponges.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

ELECTION EXPENSES FUND OF B. W. RICHARDSON, M.D., F.R.S.

ROBT. J. BANNING, M.D., } Hon. Secretaries.
CHAS. WELLS, M.D., }

Quebec Institute, Baker-street, W.

P.S.—The expenditure would have been somewhat larger had not Dr. Richardson defrayed some preliminary expenses and Dr. Danford Thomas kindly given £10 worth of stamps in addition to their subscriptions.

Mr. James Oliver.—The paper, if forwarded, shall have consideration.

M.B.—No.

OBSCURE NERVOUS AFFECTION.

To the Editors of THE LANCET.

SIRS,—Could any of your readers assist me in a case that has resisted all the ordinary forms of treatment for many months, and which is getting worse, in spite of iodide of potass., bicarb. potass., brom. potass., colchicum, Donovan's sol. of arsenic, &c. The patient, a lady over sixty years of age, is of a gouty family, but of active and very temperate habits. Her general health is good. About four years ago she was seized with numbness of the toes, which afterwards extended over the whole sole of one foot. Then the other foot became affected in the same way, and latterly the uppers of both feet as well as the soles. She feels as if walking on soft cushions, not pins and needles. Her walk on rising up is at first rather unsteady, and she kicks one foot against the other. But the knee-jerk is perfect in both, and she can walk or stand quite well with eyes closed. Moderate warmth makes them easier; but cold, or much heat, makes them feel more painful. Any hints as to treatment will be thankfully received by

Yours truly,
April 20th, 1886. PUZZLED.

REGISTRATION AND THE NEW MEDICAL ACT.

IN reply to numerous correspondents we may say that the new Act is not retrospective, and will not therefore affect gentlemen in respect of any qualifications already registered.

Massage is referred to an annoucement in our issue of April 16th, p. 44 of advertisement sheet.

Dr. A. A. Smith.—The instrument lies at our office.

HOSPITALS FOR INFECTIOUS DISEASES.

Mr. E. Turner (Stourbridge).—It has been held that one bed per thousand of the population forms ample accommodation for the permanent wants of a district. But in every case sufficient land should be taken to admit of extensions, whether temporary or permanent, owing to emergencies or to increase of population. This estimate is, of course, only a general one, and the proportion of beds to population would have to be varied according as a large or small number of the inhabitants have such dwelling accommodation as admits of reasonable facilities for isolation. The handbook relating to this subject is the Supplement by the medical officer to the Tenth Annual Report of the Local Government Board—"On the Use and Influence of Hospitals for Infectious Diseases." This can be obtained as a Parliamentary paper. The first forty pages of this Report contain a summary of the whole volume. Another useful paper is one "On the Planning and Construction of Hospitals for Infectious Diseases," by the Architect of the Local Government Board, which is contained in the Transactions of the Epidemiological Society, New Series, vol. ii. (Shaw and Sons, Fetter-lane). A copy of the diagram of an isolation pavilion, recently issued, should also be procured by application to the Local Government Board.

Mr. J. Gowans.—Cassell's Domestic Medicine would probably answer the purpose.

"EXTIRPATION OF RUPTURED UTHRUS."

To the Editors of THE LANCET.

SIRS,—Referring to the very interesting case described in your issue of April 23rd, in which Dr. Andrews performed abdominal section to enable him to deal with a rupture of the uterus and the hæmorrhage consequent thereon, allow me to endorse his comment that "such an operation ..... gives a chance to an otherwise hopeless case, and that it should be undertaken without hesitation under such circumstances." Dr. Andrews opened the abdomen, removed "a very large quantity of blood" from the peritoneal cavity, dealt with the rent in the uterus by removing the organ with its appendages, and completed the operation. But the patient barely survived the procedure, and unquestionably, as Dr. Andrews observes, the "hæmorrhage was the fatal factor in the case." My object in venturing to address you is to assert my belief that the fatal factor in such cases as these may be absolutely obviated by injecting about a pint of warm water (with or without the addition of a saline powder) into the veins. If circumstances permit the transfusion of blood, so much the more favourable will be the prognosis; but the intravenous injection of water or of saline fluid at 100° F. may generally be trusted as an efficient means of combating acute anæmia (the hæmorrhage having been arrested), in proof whereof allow me to refer to my paper on "Transfusion for Hæmorrhage in Military Surgery, published in THE LANCET of Jan. 15th, 1887.—I am, Sirs, your faithful servant,

Upper Brook-street, W., April 23rd, 1887. CHAS. E. JENNINGS.

LANGMORE DEFENCE FUND.

A SUM of about £103 is still required to settle the costs incurred by Dr. J. Wreford Langmore in defending this action, most unjustly brought against him. Further subscriptions are consequently needed, and may be paid to Mr. George Eastes, M.B., 69, Connaught-street, Hyde Park-square, London, W.

Third List.

A Very Old Subscriber.—The M.B. of Dublin University is not a licence to practise surgery and midwifery. It is a qualification in medicine only. The University supplements it with licences and degrees in surgery and midwifery.

Inquirer had better apply to some large nurseryman.

Dr. McKee is thanked, but we had already made arrangements for a report.

MALIGNANT PUSTULE AND COMA.

To the Editors of THE LANCET.

SIRS,—I have little doubt that the convulsions and coma in the remarkable case of coma due to malignant pustule, reported by Mr. Reilly in your issue of April 23rd, resulted from cerebral meningeal hæmorrhage. There were at least two amongst the fatal cases of malignant pustule at Guy's, in the year 1884, during the latter part of which I was acting as surgical registrar, in which death was preceded by convulsions and coma. The necropsy in these cases revealed extensive hæmorrhage over the cortex of the cerebrum beneath the arachnoid. Of course, in addition to this, there were other lesions discovered characteristic of death from malignant pustule. I do not think we ought to be surprised when we meet with subarachnoid hæmorrhage in these cases, considering how frequently we meet with extravasations of blood under other serous surfaces, as the pleura, &c.; in fact, I should be inclined to look upon meningeal hæmorrhage, like œdema of the glottis, as not a very unfrequent complication which may directly induce a fatal termination in a case of malignant pustule. I am, Sirs, yours faithfully,

St. Thomas's-street, April 25th, 1887. L. A. DUNN, B.S.

THE LATE DR. CARRINGTON.

WE are asked to state that Mrs. Carrington and family desire to express their gratitude to the very many friends who have sympathised with them in their recent bereavement, and whom they find it impossible to address individually.

Mr. Charles Williams.—We cannot learn that Schwartze's Aural Surgery has been translated into English.

Mr. Strathearn (Govan).—The address of the Secretary is 25, Wynne-road, Brixton.

"FRIENDLY SOCIETIES' MEDICAL ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "M.O., F.S.M. Assoc.," who appears so contented with his lot, does not consider the bearing of his position with regard to these monopolies in relation to the profession generally. Our experience in Loughborough is that the abuse of the "medical aid" is most flagrant. It includes professional men, tradespeople, the upper classes of artisans, and, in fact, makes a clean sweep of about 6000 people, out of a population of 18,000 of all classes and conditions. For this reason the medical men of the town have refused from the first to co-operate with the medical officer. An institution which has for its aim to obtain medical services at the cheapest rate, and whose payment of their medical man would compare unfavourably with that for service under the Local Government Board, in many instances, cannot command our support, when we consider for whom it partly, if not mainly, exists, not the poor of the labouring classes, but the thrifty and well-to-do artisans, the prosperous tradesmen (small and large), and professional men, not to mention a large number of the publicans. Your correspondent may, from his commercial point of view, consider that his political economy is good, but I beg to suggest that the lowering of our fees to the rate of 2*d.*, 3*d.*, or 4*d.* for a consultation in the case of people such as I have indicated is not good either for the medical profession or the general public. It is defrauding the really necessitous in the interest of the mean, who in their saving do not consider how they save. Than this no subject, to my mind, is more urgent. We wish for equal titles for medical men, and for conjoint examining boards, but the "battle of the shops" is quite secondary to the question of whether general practice is to be swamped in a co-operative medical store. If the Council would take up the questions of medical charity, provident and otherwise, and friendly societies' associations, and make some effort to prevent the great abuse at present existing, it would be doing more useful work than altering regulations as to preliminary education. And I believe that a commission instituted by THE LANCET to investigate these matters would open the eyes of the profession to the snare which is gradually being thrown around it. If these miserable contracts become general, we shall cease to be a liberal profession, the general practitioner will be merged altogether in the "club doctor," and will become more than ever an over-worked and subservient drudge.

I am, Sirs, your obedient servant,

Loughborough, April 16th, 1887. J. B. PIKE.

To the Editors of THE LANCET.

SIRS,—The medical officer whose letter appeared in your issue of the 16th inst. is to be congratulated on his good fortune. The association I was in contained over 4000 members, and the committee were composed of working men who appeared to have no respect whatever for the surgeons. The work was heavy. The hours at the surgery were 9 to 10 A.M., 1 to 2 and 6 to 8 P.M., and all know how patients rush in at the last and keep one at work long after the time for leaving. Visiting was done between times. One of the worst faults of this system is the liberty people with a morbid faith in medicine have to come and demand a bottle of medicine whenever they like. For advice they care nothing, and the surgeon is reduced to little better than a puppet. If "M.O., F.S.M. Assoc." had his members increased to 4000 and the committee of that peculiar democratic character that tries to raise itself by degrading others, and with no increase of salary, he would form a very different opinion of such places. The life of an assistant with a general practitioner is better, as far as social position goes. In an Association one's social position is sacrificed; but if abuses were cleared out, all fees given to the surgeon instead of to the committee, and patients taught to respect a surgeon and his house, life would be vastly preferable there than in a position where you have to please two parties—viz., the principal and the patients—and be at the mercy of the whims of both. I cannot see sufficient reason why all fees subscribed by members for the surgeon should go to the committee, and only a portion be handed over to the surgeon. The surgeon should receive all fees, supply drugs, and the clubs should pay the expenses of management. The present club system is disagreeable and wrongly based, as members, when once a surgeon is chosen, are bound to go to him, however much they may dislike him, or pay another, and the surgeon is obliged to attend to many who he knows would rather not have him. This makes club work almost unbearable at times, and often leads to such bickerings and quarrels that many surgeons look forward to the day when they can get quit of clubs and others refuse to have them. A much better plan would be for each club to have a list of surgeons willing to take club members, each member to choose for himself. A surgeon would receive from the various clubs his list of members. This would give more freedom to both parties and do away with three-quarters of the present causes for bitterness and complaints.—I am, Sirs, yours sincerely,

April, 1887. M.B.

THE FOOD OF PARIS.

THE last municipal report relating to the sale and consumption of food in Paris contains an estimate showing the average consumption per head of the population, and from this it would appear that each inhabitant eats 169 lb. of meat, 9 lb. of "triperie" (which includes calves' head, tongue, kidneys, &c.), 26 lb. of fish, 25 lb. of poultry, 8 lb. of oysters, 17 lb. of butter, 5 lb. of cheese, and 15 dozen eggs. The report does not give the quantity of bread eaten by the population of Paris, but the average price of it during 1886 was as nearly as possible, allowing for the fractional difference of money, 3½*d.* per lb. The total quantity of meat consumed during last year in Paris was about 150,000 tons weight, this representing 302,894 head of cattle, 188,595 calves, 1,979,526 sheep, and 352,001 pigs, while in addition to this nearly 4000 tons of horse, mule, and donkey flesh were sold in the city, at the average wholesale rate of 3*d.* per lb. The quantity of fish sold was considerably in excess of the total for the previous year, the increase being most marked in the oyster trade, the total weight being greater by 1720 tons.

Sigma (Ostend).—The International Congress of Hygiene will be held between Sept. 26th and Oct. 2nd at Vienna. The first day's sitting will be signalised by a paper on the Mode of Propagation of Abdominal Typhus, by Dr. P. Brouardel, Dean of the Medical Faculty of Paris.

Dr. Bell Taylor.—No.

PROPOSED ARCHITECTS AND ENGINEERS' REGISTRATION ACT.

To the Editors of THE LANCET.

SIRS,—Will you allow us to call the attention of your readers to an important movement contemplated by the architectural profession? At the present time it is open to anyone, however ignorant he may be of sanitary science and construction, to practise as an architect, to the great danger of the general health of the public. In order to put an end to this unsatisfactory state of matters, the Architectural Federation Committee (a body elected for the special purpose at a public conference of architects held in April last) are endeavouring to obtain for the profession an Act of Parliament, such as the Medical Act, for the compulsory registration and proper education and examination hereafter of all desiring to enter its ranks. The proposed Bill is now drafted, and a public meeting is to be held on Wednesday, May 4th, at 4 o'clock, at St. James's Hall, Regent-street, London, W., when the principles of the Bill will be discussed. It must be well known to most of your readers that a vast amount of illness which comes under their notice is caused directly or indirectly by badly-drained, ill-ventilated, damp or otherwise faultily-constructed dwellings. It is hoped, therefore, that all who feel the necessity of architects being properly educated, especially in matters of sanitary science, of which so many are so utterly ignorant, will endeavour to attend.

We are, Sirs, your obedient servants,

HUGH ROUMIEN GOUGH, Chairman.
April 25th, 1887. EDGAR FARMAN, Hon. Secretary.

THE RED CORPUSCLES.

J. G. S. (Barrow-in-Furness).—At the last sitting of the Reale Accademia di Lincei of Rome (the Italian equivalent to our Royal Society) the following were among the "Note" presented for insertion in the "Atti":—(1) Cadaveric Alterations of the Red Corpuscles and the Formation of the Coagulum; (2) Formation of Pus from the Red Corpuscles of the Blood; (3) How Leucocytes are derived from the Red Corpuscles of the Blood; (4) Degeneration of the Red Corpuscles of the Blood. The series of "Note" were all from the pen of Prof. A. Mosso of Turin.

Mr. D. Donald.—The attention of the body from whom the gentleman derives his qualification should be drawn to the matter.

"INHALATION OF COAL-GAS AS A SOURCE OF DISEASE."

To the Editors of THE LANCET.

SIRS.—The action of coal-gas on the throat and head has been underestimated. I have had most unpleasant experience. I live in an old house, and although the gas fittings in the bedrooms were massive and good still the gas escaped. I got a clever workman to come down from London, and he told me that every joint wanted oiling; I found he was quite correct, and the rooms are free from smell. He further said that people expected the joints to remain tight for years without any attention. Another great safeguard against escapes is to have the tap on the fixed end of the bracket and not on the branches, for then the pressure of gas does not act on the joints in the bracket.

I am, Sirs, yours faithfully,

April 25th, 1887. THOS. CHRISTY.

OBESITY.

To the Editors of THE LANCET.

SIRS,—Would any of your readers be so kind as to inform a brother practitioner as to what is practically the best treatment to be adopted in a case of excessive obesity? I have unfortunately had no experience in the treatment of such cases.—I am, Sirs, yours faithfully,

April 25th, 1887. A SUBSCRIBER.

CIPRIANI THE FORK-SWALLOWER.

FIFTEEN years ago, it may be remembered, Egisto Cipriani, a journeyman printer of Florence, as the result of a bet, introduced a fork down the œsophagus into his stomach. Every method short of surgical interference was tried to extract it, but in vain, Cipriani meanwhile being from time to time so ill as to have to take to bed. Prof. Rosati, the eminent surgeon of Florence, has at length persuaded him to submit to the operation of gastrotomy, the result of which will shortly be made known.

Dr. James G. Robertson.—St. Thomas's Home, in connexion with St. Thomas's Hospital, would probably receive the patient.

Homœopathist should send the documents to a journal devoted to the advocacy of the system.

Dr. Aikman (Guernsey).—The article had been arranged for.

Mr. Stewart.—In an early number.

THE OPEN-AIR TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Dr. Burney Yeo, in his most interesting and instructive lecture upon Gaseous Rectal Medication in Pulmonary Affections (THE LANCET, April 16th, p. 761), alludes to a case which I noted in the *British Medical Journal*, Dec. 1886, p. 1098, as illustrating the value of open-air treatment of phthisis, many highly interesting papers and cases of which mode of treatment are quoted in Sections 695: 6 of the Medical Digest and Appendix. Dr. Yeo, by his remarks, seems to infer that the vast benefit derived by the open-air treatment of this case was really due to the use of antiseptics. This I am not at all inclined to admit, for in two other members of the same family antiseptic treatment alone was most carefully carried out, with, alas, unsatisfactory results; whereas my patient, living day and night in the open air, rapidly recovered, his health being at the present time most satisfactory.

I am, Sirs, yours obediently,

RICHARD NEALE, M.D. Lond.

Boundary-road, N.W., April 27th, 1887.

Mr. J. Jackson (Sowerby).—Our correspondent appears to have been rather hardly used.

Dr. Lewers.—The paper, if sent, shall receive attention.

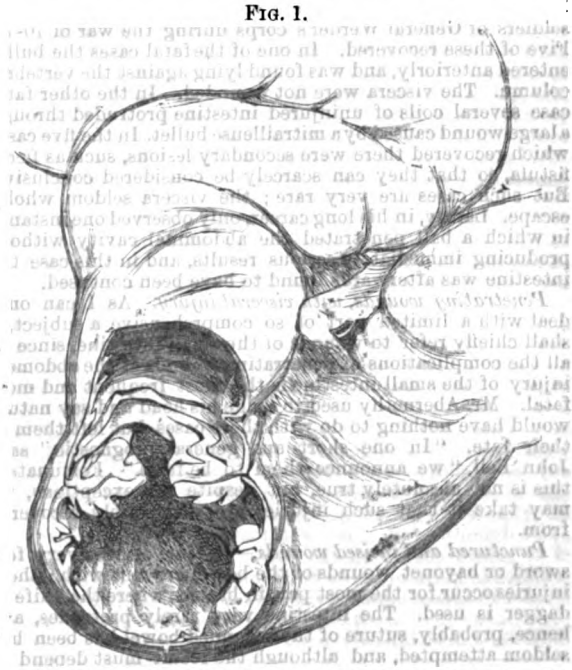
An Oration
ON
ABDOMINAL SECTION FOR THE TREATMENT OF INTRA-PERITONEAL INJURY.

Delivered to the Medical Society of London, May 2nd, 1887,

BY SIR WILLIAM MACCORMAC,
SURGEON TO ST. THOMAS'S HOSPITAL.



MR. PRESIDENT AND GENTLEMEN,—The subject of abdominal surgery is so wide that it may be said to possess a literature of its own. The condition of the kidneys, intestine, stomach, uterus, and spleen, which indicates surgical intervention has been very fully considered, and lately diseased states of the pancreas and liver. There is one class of cases, however, which has received less consideration than the rest—at any rate, in the light of our newer knowledge and experience, and that is the treatment of penetrating abdominal wounds and visceral injury. My attention has been directed to the subject by the recent occurrence in my own practice of two cases of intra-peritoneal rupture of the bladder produced by external violence. In both of these the abdominal cavity was laid freely open, the rent in the bladder closed by suture, and the peritoneal cavity effectively purified. In each instance the patient completely recovered, and two men, the subjects of a heretofore fatal injury, were restored to perfect health. Another case of the same kind has been since successfully operated upon in a precisely similar manner by Mr. Walsham at St. Bartholomew's Hospital. My colleague, Mr. Croft, has courteously placed at my disposal the record of a case which, if not in itself completely successful, points out how success is to be realised. It is so interesting that I shall give a brief account of it.

G. W——, aged thirty-four, labourer, was admitted into St. Thomas's Hospital on Sunday, March 6th, at 2 o'clock. Seventeen hours previously he had received an injury to the abdomen in a public-house row. He stated that he had been jumped upon. He had no medical advice before reaching the hospital. During the night he was in great pain and was sick two or three times. On admission the patient's temperature was 103°, and he was thought to have peritonitis. Mr. Croft was sent for. He decided at once to explore the abdomen by median laparotomy. The operation was performed eighteen hours and a half after the accident. Three lesions were discovered. The ileum had been ruptured tranversely to the extent of two-thirds of its circumference at the junction of the lower and middle thirds. The lower surface of the mesentery in the same neighbourhood presented a laceration about an inch and a half in diameter, and the omentum, above the level of the umbilicus, had a considerable rent in it. There was fæcal extravasation, and septic peritonitis had spread into the iliac, umbilical, and hypogastric regions. Enteroraphy was debated, but postponed under the circumstances in favour of artificial anus. The peritoneum was very carefully irrigated and rendered aseptic with a warm solution of boracic acid from 15 to 20 per cent. in strength. The edges of the ruptured intestine were closely attached to the parietal wound, and the rest of the incision closed in the usual manner. The operation lasted an hour and a half, and the man was kept during this time under the influence of ether. He became much exhausted. The pulse was very feeble and the hands and feet cold. He recovered satisfactorily. The symptoms of peritonitis disappeared, but a sharp attack of bronchitis ensued. This yielded to treatment, but he did not gain strength or flesh, partly by the irrepressible escape of intestinal contents at the artificial anus and partly by the local irritation established in the abdominal wall by the contact of the intestinal secretion. At the end of four weeks Mr. Croft proceeded to close the artificial anus. The patient was prepared for the operation, which was performed on April 4th by substituting rectal feeding for alimentation by the mouth, and by local irrigation of the intestine and all parts immediately concerned. The bowel was then separated from its parietal attachments, the injured portion resected, and the cut surfaces carefully united by twenty-six sutures of fine silk; twenty of these were in one row, after Lembert's manner of suturing. The operation lasted two hours and a quarter, and the patient was taking ether all that time, with the exception of a quarter of an hour, when his circulation was so feeble that the anæsthetic was discontinued and a brandy enema was administered. The patient died on April 5th, thirteen hours after the operation. The lungs were found very congested and airless. The suturing had been perfect, and the peritoneum was entirely free of any recent exudation or inflammatory products. (Fig. 1.) Had the natural force of the man been a little greater he might have made a good recovery.

Mr. MacKellar, in a case of gunshot injury of the sigmoid flexure, recently opened the abdominal cavity, but found it impracticable to apply Lembert's suture to the intestinal perforations caused by the bullet. The patient was in a state of impending collapse at the time of the operation, and died twelve hours afterwards.

Again, Mr. Croft nearly achieved success in a case of rupture of the spleen. The patient, a young man, had been

FIG. 1.

Appearance of the sutured portion of the bowel after death.

run over by a cab, but no effective assistance was rendered to him, and when brought to the hospital twelve hours afterwards the abdominal cavity was full of blood. Laparotomy was performed and the ruptured spleen removed, the peritoneal cavity being cleared of blood and purified; but the patient never rallied from the state of collapse and died the same evening.

Cases such as these are somewhat closely connected. They suggest many points of interest, and invite consideration to the large question of abdominal injury, more especially in regard to its treatment by operation. I would urge the propriety of a more frequent resort to abdominal section and exploration of the abdominal cavity and contents than has been heretofore adopted in cases of injury in—1. Incised and punctured wounds of the abdomen implicating the intestine or other viscera. 2. Abdominal gunshot wounds, chiefly as they affect the intestine. 3. Traumatic rupture of the intestine and viscera without external wound.

Stab wounds of the abdomen.—These may be either simple penetrating wounds without injury to any of the contained viscera, or accompanied by visceral injury. Simple penetrating wounds of the abdominal cavity are very rarely inflicted either by sharp or blunt weapons or by gunshot. There are upon record many apparent exceptions to this

Digitized by Google

statement, but some of them may be explained by the circumstance that the weapon or projectile has evaded the abdominal cavity which it apparently enters, or when traversing the cavity has produced an injury susceptible of repair. A sword thrust may traverse the abdomen, and the bowel, subsequently prolapsed through the wound, be found uninjured. During the American war an Apache Indian prisoner, attempting to escape, was transfixed by a bayonet and pinned with it to the ground. The weapon entered the left hypochondrium, passed directly backwards, and made its exit about two inches from the vertebral column. No bad symptom followed, and the wound had healed on the fourth day. An instance is recorded where an iron-headed arrow entered three inches to the right of the fifth lumbar spine and emerged two inches to the right by the ensiform cartilage. Circumscribed peritonitis ensued, but the patient recovered without other ill consequences. Heusen records the recovery of a soldier shot through the abdomen with a ramrod at Badajos in 1812. During the American war in 1863 a ramrod entered the left groin of Private Manypenny and emerged through the left lumbar region. The surgeon records his diagnosis as "a ramrod driven plump through the guts." There was no serious peritonitis, and the man returned to duty two months later. Beck quotes seven cases of penetration of the abdomen by bullets, without any apparent visceral injury, occurring in soldiers of General Werder's corps during the war of 70-71. Five of these recovered. In one of the fatal cases the bullet entered anteriorly, and was found lying against the vertebral column. The viscera were not wounded. In the other fatal case several coils of uninjured intestine protruded through a large wound caused by a mitrailleuse bullet. In the five cases which recovered there were secondary lesions, such as fæcal fistula, so that they can scarcely be considered conclusive. But such cases are very rare; the viscera seldom wholly escape. Larrey, in his long career, only observed one instance in which a ball penetrated the abdominal cavity without producing immediately serious results, and in this case the intestine was afterwards found to have been contused.

Penetrating wounds, with visceral injury.—As I can only deal with a limited part of so comprehensive a subject, I shall chiefly refer to wounds of the small intestine, since of all the complications of penetrating wounds of the abdomen, injury of the small intestine is the most frequent and most fatal. Mr. Abernethy used to shake his head and say nature would have nothing to do with these cases, but left them to their fate. "In one short and general prognostic," says John Bell, "we announce them to be fatal." Fortunately this is not absolutely true, but despite the exceptions, we may take it that such injuries are very rarely recovered from.

Punctured and incised wounds.—In time of war very few sword or bayonet wounds of the bowel are met with; these injuries occur for the most part in brawls, where the knife or dagger is used. The intestine very rarely protrudes, and hence, probably, suture of the wounded bowel has been but seldom attempted, and although the result must depend to some extent on the empty or collapsed condition of the bowel at the time of injury, unless the puncture be very small, there is no likelihood of recovery without suture. When extravasation occurs, peritonitis almost necessarily follows, although in a few instances a fortunate agglutination of adjacent coils may prevent it and recovery ensue.

Diagnosis.—The diagnosis of wound of the bowel is of primary importance, as upon the speedy determination of this point and prompt consequent action must almost altogether depend the success of our treatment. When the injured intestine is prolapsed through the wound, or the contents of the tube escape externally, the diagnosis is clear; but these occurrences are the exception, and the presence of a wound of the intestine in the early stage must be often mere matter for conjecture. Tympanites and discharge of blood per anum are valuable symptoms when present, but neither may appear directly after the injury. If the blood passed from the bowel be abundant and shows itself soon after the injury, it is a very valuable symptom. Emphysema, when it occurs in the wound neighbourhood, is said to be pathognomic. Shock and pain vary so much in degree as to afford no useful guidance. The amount of shock is very variable, and cannot be relied upon in any degree as diagnostic. It is often described as very trifling; at other times it may be severe. The amount of pain also offers no true criterion. The surgeon who sees the case immediately after the injury must often be in doubt as to whether the intestine be injured or not, and as to the extent of the internal damage. Probing these wounds has been very universally condemned as useless for diagnostic purposes, and harmful to the sufferer, by possibly disturbing the parts and giving rise to fæcal effusion. But this view can scarcely meet with the same consideration now in the light of modern means of treatment. If precautions be taken to exclude septic influences, the thorough examination of the wound by the probe may determine its direction and extent, and if this fail to clearly establish the fact or otherwise of penetration, the wound should be enlarged and explored to its termination, either in the parietes or more deeply. The important point to speedily determine is whether the wound penetrates the abdominal cavity, and this is perhaps the most effective manner of ascertaining it. After a short interval the occurrence of peritonitis will determine our diagnosis; tympanitic distension of the abdomen, agonising pain, ceaseless vomiting, tendency to collapse, thready pulse, and clammy surface make their appearance, and a fatal issue soon follows. When the diagnosis has been established in this way the services of the surgeon are no longer called for. Should the abdominal cavity be penetrated, the question arises as to whether the intestine has been wounded or hæmorrhage has taken place. In that event, the better treatment will be at once to make a median incision in the manner recommended for any other form of abdominal section, and not to trust to enlargement of the existing wound. Of course where the bowel protrudes and no extravasation has taken place in the interior, it will be sufficient to suture the opening in the prolapsed portion, excise after ligature any damaged portion of omentum, and return the parts, if necessary enlarging the external wound for the purpose.

Treatment.—Although the abdominal cavity has been traversed both by a bullet and sword without opening the intestine, which is presumably thrust aside, this condition of things is not to be relied upon to guide our treatment.

Enteroraphy is at the present time admittedly the best method of treatment for all punctured and incised wounds attended by protrusion, unless the parts are so damaged that an artificial anus seems preferable. In cases of stabs and gunshot wound unattended by protruaion, the common practice heretofore has been to arrest the peristaltic movements with opium and enjoin absolute rest, in the hope that adhesions may form to avert extravasation. Experience proves that in the vast majority of instances such hopes are illusory; ninety-nine times in a hundred extravasation occurs, hyper-acute peritonitis follows, and after much suffering death usually takes place within forty-eight hours.

Another practice commonly recommended is the formation of an artificial anus by attaching the margins of the wound in the gut to the skin; but where it is possible to avoid it this course is in the highest degree undesirable, and certainly unnecessary in those cases where the injury does not extend more than half-way around the calibre of the tube, or where the convexity of the bowel is wounded; probably also in all cases where the mesenteric attachment is intact; and the same may be said where the bowel is ruptured by external violence. This practice gives the surgeon a false sense of security; he thinks if his sutures give way the patient may still recover, but the evidence is very strong that the risk of fæcal extravasation is less when the wound in the bowel is completely closed and the gut at once returned to the abdominal cavity. A different practice properly obtains where the bowel is gangrenous in hernial or other forms of strangulation. An artificial anus should then be established in preference to immediate resection of the gangrenous portion of bowel with suture of the divided ends. In such cases the bowel is in an unhealthy condition. We do not exactly know the limits of the gangrenous action or of the zone of inflammatory infiltration beyond it, and therefore cannot precisely determine what amount of damaged bowel it is necessary to remove. In cases of injury, however, we shall have but half accomplished our work if we do not at once attempt to restore the continuity of the intestine. Should the patient recover, a further operation will be required to close the fæcal fistula, and this procedure is often one of great difficulty and serious risk. Besides, should the original damage be in the upper portion of the small intestine, there is a considerable probability of the individual being either starved or so weakened by the escape of nutriment that he becomes unfit to be submitted successfully to any operation whatever.

Intestinal suture.—There are three conditions required to ensure successful suture of the intestine. 1. Two adequately

Digitized by Google

broad and sufficiently wide surfaces of peritoneum must be brought into contact. 2. The mucous membrane must be excluded; for when the needle passes through the whole thickness of the gut peritonitis generally ensues from leakage taking place along the line of the thread. 3. Rapidity of execution is of extreme importance, and that form of suture is the best which can be effectively applied in the shortest time.

In 1826 Lembert introduced a method of bringing the two adjacent serous surfaces into contact, avoiding penetration of the mucous coat. It is the preferable one to employ in all wounds of the bowel. Sufficient inversion may be thus easily accomplished without causing obstruction of the lumen of the tube. When the wound is small or incised, the needle may be introduced a line and a half or two lines from the margin and then brought out at the edge of the serous coat, the same being done on the opposite side. This will suffice in clean-cut wounds, but where the edges are bruised it is best to exclude them by entering the needle about three or three and a half lines from the margin, and carrying the suture through the bowel a line distant or more from the edge. The number of stitches must be sufficient to bring the parts everywhere into accurate contact, and care taken not to tie the sutures too tightly, as it may lead to gangrene and consequent failure to procure union. Experimentally this has been found to be the most frequent cause of non-union. The ends of the sutures are cut short and the intestine returned to the abdominal cavity. When drawn together sufficiently to bring the surfaces fairly into contact, the subsequent swelling will hold the parts firmly until the rapidly formed adhesive material securely glues them together. When the omentum is much injured it is probably best to excise the damaged parts after ligature.

The abdominal cavity must be perfectly cleansed of all blood and foreign matter. Irrigation with a 3 per cent. solution of boric acid at a temperature of 100°, made with water previously boiled, is the best and gentlest method. The external wound is closed as after ovariotomy. If the operation be done shortly after the accident drainage may be dispensed with. If some time have elapsed, or if peritoneal inflammation be present, it will be best to drain. The presence of a drainage-tube in the wound certainly enhances the risk run by the patient, and it is best, therefore, to dispense with it in all cases where it appears safe to do so.

Gunshot wounds.—Gunshot wounds of the intestine are injuries of the most fatal description. They are of frequent occurrence in time of war, and far from being rare in civil practice, especially in America, where everyone carries a revolver and often uses it on small provocation. About one-tenth of those slain in battle perish from abdominal injury, but only 3 or 4 per cent. of those who come under treatment are wounded in the abdomen. These wounds are almost invariably concealed, the gut being seldom protruded. Wounds of the duodenum are comparatively rare, and usually associated with other severe injury. The jejunum is more frequently wounded; but the ileum is the most frequent seat of gunshot injury; damage to other parts is generally present, or a multiple wound of the intestine itself. Alexander relates a case occurring in the Crimea where the intestine was wounded in sixteen places by the same bullet. If this were common operative surgery would prove of little avail; but seldom more than two convolutions are perforated, or the intestine wounded in more than four places. In a few instances the bullet may perforate and lodge in the bowel; this is proved by its being voided at stool shortly after, and this happens most frequently in wounds of the large intestine. When discharged per anum at an early period, the bullet has presumably penetrated the gut; when the missile is passed at a late period it probably gained admission to the tube from some adjacent part by secondary ulceration or abscess.

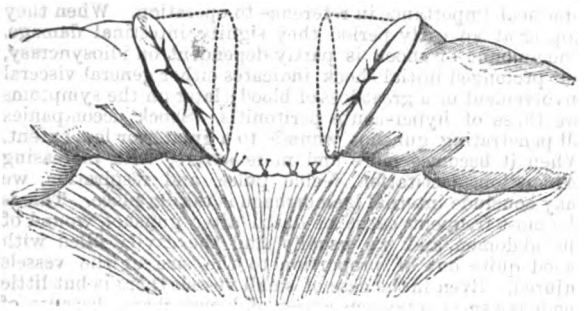
Symptoms and diagnosis.—In gunshot injuries the first question to ascertain is if the bullet have penetrated the abdominal cavity. The external wound should be carefully probed, or it may be enlarged sufficiently to explore its whole length as it passes through the abdominal wall. This adds little to the gravity of the patient's condition, and will positively determine whether the wound is a penetrating one. These injuries are attended with considerable hæmorrhage, great and prolonged shock, lowered temperature, feeble rapid pulse, restlessness, severe pain, great anxiety, and rectal tenesmus, and there is always extravasation of fæces into the peritoneal cavity, although it is very rare for any sign of them to appear externally. The absence of fæcal matter in the parietal wound is no proof that the intestine is not perforated. In none of Professor Parkes' numerous experiments on dogs did any fæcal matter emerge through the external wound, although in many instances large quantities were found in the peritoneal sac, and Gross showed that fæcal extravasation into the peritoneal cavity occurred in every instance. The mucous membrane never blocked the perforation produced by the smallest bullet so as to prevent it—a strong point in favour of active interference. Air in the abdominal cavity, causing tympanites, emphysema around the wound, a larger escape of blood than the injury to the parietes will account for, are among the symptoms which help to indicate intestinal injury. The occurrence of bloody stools is usually a late symptom, and without practical importance in reference to operation. When they appear at an early period they signify intestinal damage. The amount of shock is partly dependent on idiosyncrasy, but prolonged initial shock indicates either general visceral involvement or a great loss of blood; later on the symptoms are those of hyper-acute peritonitis. Shock accompanies all penetrating gunshot wounds to a greater or less extent. When it becomes more and more severe, with increasing exhaustion, jactitation, feeble pulse, and respiration, we may conclude internal hæmorrhage is taking place. This is the most frequent cause of death after gunshot wound of the abdomen, and we usually find the cavity filled with blood quite out of proportion to the size of the vessels injured. Even in the case of small vessels there is but little tendency to spontaneous arrest of hæmorrhage, because of the laxity of the tissues and the absence of atmospheric influence in producing coagulation. As soon as air is freely admitted by abdominal section the bleeding from the lesser arteries is speedily arrested. When a large vessel is injured the bleeding is always excessive, and a fatal result almost directly follows.

Treatment of gunshot perforation of the intestine.—The experiments on dogs prove how futile it is to expect immunity from either intestinal perforation or extravasation of fæces after a bullet has traversed the abdomen; and the same is true of man. The bowel is nearly always perforated, fæces are extravasated, and very frequently there is some other serious injury as well. It will be more reasonable, then, to submit the patient to the less serious risk incurred by abdominal section than to leave him in deadly peril from the consequences of a wounded intestine or a bleeding vessel on the mere assumption that they may possibly have escaped injury. Some degree of doubt must always exist on account of the necessary obscurity of the symptoms, except in the rare event of prolapse of the injured gut, fæcal extravasation appearing externally, or very free hæmorrhage from the wound. But although there may be uncertainty as to the extent of the lesion, it is surely better to solve the doubt by an exploratory abdominal section, which may afford the only possible means of rescue. If we await the outbreak of peritonitis, the patient's chances of recovery after operation will be greatly diminished. Operation is practically useless after twenty-four hours have elapsed, or when general peritonitis and great collapse have set in. A slight amount of peritonitis, however, by no means contra-indicates operation. If we are satisfied that laparotomy is the proper proceeding, and decide to explore the abdomen, the operation should be undertaken as soon as possible after the infliction of the injury, and performed with every antiseptic precaution. When it has been delayed, the condition of shock is so much aggravated by the necessarily prolonged operation that it may be impossible to complete the thorough disinfection of the cavity. The median incision must be sufficiently extensive to allow all parts of the abdomen to be explored; it should be large enough to admit the operator's hand, and none but his should ever be allowed to enter the peritoneal cavity. The mere enlargement of an existing wound is inadequate for the purpose of thorough exploration. The bullet wound in the abdominal wall should be explored when necessary for purposes of diagnosis, otherwise it ought simply to be disinfected and included under the general dressing. Abdominal section enables us to determine the extent of the injury and the treatment which should be adopted. The entire cavity and its contents can be thoroughly examined. An injury is less liable to be overlooked, and the suture of the bowel is more readily accomplished. The operation is incomplete unless the entire intestinal tract be examined as well as the stomach and other viscera, which, of course, entails considerable

Digitized by Google

manipulation. The intestines must be withdrawn, carefully examined, and protected as far as possible by warm cloths. The best way is to seek the cæcum first, and then trace the small intestine upwards for its entire length; in this way we shall be least likely to fail to find the injury. All bleeding points must be secured and the clots swept away. When several openings exist close together, it is better to resect the portion of intestine involved. In some instances, when the bowel wall is seriously compromised at one or more distant points, multiple resections have been made. Ingenious clamps, such as those of Rydygier, Treves, and others, have been suggested, but

FIG. 2.



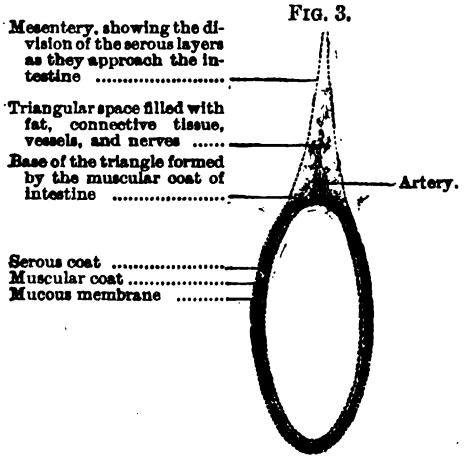


Illustration of the appearance of the resected bowel with its edges much everted previously to the introduction of the sutures. In the margins of the separated portion of mesentery four points of suture have been introduced after the vessels were secured by ligature.

When a complete resection of the bowel is performed, the margins of the opening in the gut should be divided in a slightly radiating or oblique manner, so as to remove rather more on the convex than the concave or mesenteric border. When the Lembert's suture is tied, the channel of the united portion of the bowel will thus be straighter, and there is less liability to interference with the free passage of its contents at the point necessarily narrowed by the suture. The mesentery should be cut through as close as possible to the intestine, and after all bleeding has been arrested, the two cut edges are sutured together.

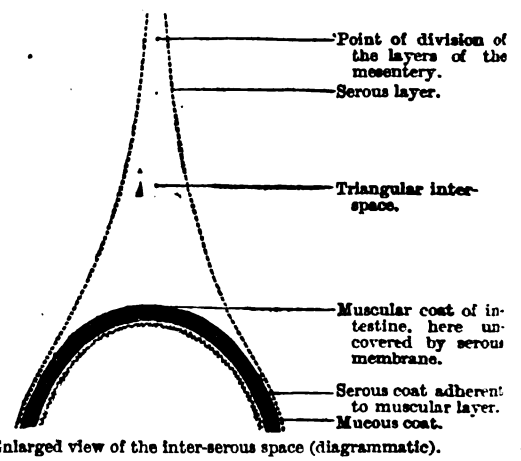
the fingers are probably the best form of instrument to prevent the escape of the intestinal contents after division of the tube. The mesentery must be detached from the part of the gut to be resected. When a large portion requires removal, a triangular piece of mesentery may have to be excised, taking care to secure separately every bleeding point. The mucous coat becomes much everted (Fig. 2), sometimes seriously interfering with the introduction of the sutures

FIG. 3.

Semi-diagrammatic section of the jejunum (natural size). The muscular layer through which the sutures are passed is comparatively thick,

and the accurate approximation of the surfaces of the bowel. It should not be excised, as it gives support, and supplies blood to the edges of the gut. In all the experiments where it was cut off by scissors the sutures gave way (Parkes). Care must be taken to insert the sutures at the mesenteric border sufficiently deep to ensure complete inversion of the intestine, and to bring the serous surfaces fairly into contact. There is a triangular interval (Figs. 3, 4, 5), filled with connective tissue and bloodvessels, between the layers of the peritoneal coat as it leaves the bowel to form the mesentery. At this place the needle must be passed deeply enough to include the muscular coat as well as the serous, otherwise extravasation will result. Three sutures should be first introduced at the mesenteric border in the manner insisted upon by Parkes. A suture had then better be placed at the convexity of the bowel, then one half-way down on each side, the others following in order in the quadrantal intervals between. Each suture should be introduced not less than a third of an inch from the divided margins, brought out just free of

FIG. 4.



Section of ileum, from the same subject (natural size).

Figs. 3 and 4 illustrate the comparative thickness of the wall of these two portions of the intestine, and show how thin the muscular layer is in the ileum.

the edge on one side, then reintroduced close to the opposite edge, and made to include about the same width of tissue. It should include only the serous and muscular layers. In cases of complete resection of the bowel it is best to include a considerable width of serous membrane. It is more difficult to pass the sutures in succession one after the other all the way round; the mucous membrane is in the way, and the sutures are apt to be uneven. Fine silk is the best material to employ, and a moderately curved needle. Czerny's double row is very tedious to apply, and as it gives no better results than the single row, including a sufficient width of tissue, it had better be abandoned on

FIG. 5.

account of the loss of time it entails, or, if used at all, it can only be necessary along the mesenteric border. The condition of the solid viscera must then be examined and any injury found in them dealt with according to circumstances. This will, however, prove a very fatal complication.

Abdominal injury without external wound.—Violent contusion of the abdomen may result in rupture of any of its contained viscera, a condition for which laparotomy has been very rarely performed.

Digitized by Google

Rupture of the intestine.—In these cases an exact diagnosis must always be very difficult, oftentimes quite impossible to arrive at, as the symptoms are obscure and common to several degrees and kind of injury. Serious hesitation must always occur when we are called upon to decide in the presence of each particular case what is the best line of treatment to adopt. One has seen many cases of severe abdominal injury recover, while many very speedily die. The most serious injury is sometimes unaccompanied by any definite diagnostic symptoms.

Symptoms and indications for operation.—The chief indications for operative interference are afforded by the mode of action and severity of the violence, the presence of prolonged and profound shock. The duration of the shock is of greater importance than its intensity. A small and quick pulse and hurried respiration, while the temperature remains either normal or subnormal, associated with acutely severe, persistent, and localised pain, increased on pressure, indicate the serious nature of the injury. Bloody vomit or stool, rapid tympany, the evidence of percussion, are inconstant signs, and help us but little. The jejunum and ileum are the portions of intestine most frequently ruptured, and the rent will generally be found just behind the part of the abdomen which has been struck—a fact which can easily be verified by experiment. In about 15 per cent. of the cases more than one loop of intestine is damaged, and in that case the injury generally occurs in super-imposed coils. It is difficult at first to distinguish the syncope induced by hæmorrhage from the shock caused by a ruptured intestine. In the early period we shall have to arrive at a diagnosis from the nature and violence of the injury and the general condition of the patient. When peritonitis is declared, an exploratory operation is urgently indicated, as collapse comes on very quickly, sometimes very suddenly, and a few hours' delay may negative all prospect of recovery.

Treatment.—Absolute rest has hitherto been the chief indication for treatment. But cases do arise in which abdominal section should be practised, and an attempt made to discover and deal with the visceral wound, arrest the bleeding, and clear away the clots and extravasated blood. We should interfere when we possess a reasonable belief that the intestine is ruptured. We may in some cases properly propose laparotomy as a means of diagnosis, and, indeed, when intestinal rupture is suspected, the operation should be performed at once to afford a good prospect of success. Exploratory laparotomy has no very serious inconvenience, and should be adopted in those cases where there are reasonable grounds for believing the intestine has been damaged, as in no other way can effective assistance be rendered to the patient. At a later period we have not only the ruptured intestine to deal with, but a septic peritonitis, which produces the most profound depression, and often necessitates an undue curtailment of some essential step in the operation, or occasions the death of the patient before its completion. Extreme collapse, a long interval from the time of the injury, or severe coexisting damage to the spleen, liver, or pancreas, of course contra-indicate operation. The incision should be made in the middle line in all cases, and at the level which will afford readiest access to the seat of the injury. It is desirable to make it long enough to permit the surgeon to reach without difficulty every part of the interior. According to circumstances, we may then decide to suture the intestinal wound, resect the injured portion of the bowel, or make an artificial anus. The same objections hold in regard to the latter that obtain in respect of artificial anus after gunshot injury. Where it is at all practicable, I believe it best to finally close the opening in the intestine and also the external wound.

THE SEWAGE OF MANCHESTER.—The Rivers Committee of the Manchester Town Council have prepared a report containing particulars of a scheme for dealing with the sewage of the city. The scheme, which is that of the city surveyor, comprises an extensive system of main drains which will carry the sewage of the entire city to Davihulme, where it will be dealt with by precipitation works on the principle of those now in successful operation at Leeds. The effluent water will pass into the river Irwell, which stream, by the means to be adopted, will be relieved of much of its impurity. The maximum expenditure to be incurred to cover works, land, easements, and all other contingencies is set down at £500,000.

A Clinical Lecture

ON THE

PATHOLOGY AND TREATMENT OF LARYNGISMUS, TETANY, AND CONVULSIONS,

ILLUSTRATED BY CASES OF THESE DISORDERS IN CHILDHOOD, AND ALSO BY A CASE OF THE TETANY OF ADULT LIFE.

BY W. B. CHEADLE, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, PHYSICIAN AND JOINT LECTURER ON MEDICINE TO ST. MARY'S HOSPITAL.

LARYNGISMUS, tetany, and convulsions are different expressions of the same constitutional morbid state, are associated especially with the first two years of life, with the period of rickets, and with the period of dentition. They are all distinguished by the occurrence of muscular spasms. In the first by a transient spasm of the laryngeal muscles, lasting only for a few seconds, and then ceasing absolutely during an indefinite period of rest. In the second by a persistent tonic spasm of the flexors and adductors of the hands and feet, varying in degree, liable to exacerbations, but never relaxing absolutely. When this is at its worst the cramps are painful. There is also twitching and fibrillar contraction to be obtained of the orbicularis and levator anguli oris on stimulating the skin by scratching over the pes anserinus[1] In the third the whole of the voluntary muscles are usually involved, and there is loss of consciousness. There may be complete relaxation between the attacks, or more or less continued rigidity of certain groups—as the flexors of the hands and feet, for example.

Laryngismus, tetany, and general convulsions are the positive, comparative, and superlative of the convulsive state in children. Convulsions no doubt occur in special circumstances apart altogether from laryngismus and tetany, and the peculiar constitutional state with which they are, as a rule, associated—as, for example, as a result of the irritation of round worms in the intestine, of undigested food, of irritation of the dental nerves; and in uræmia and in meningitis. But in the vast majority of cases there exists as a predisposing cause a special constitutional state, in which the nervous system is in an extreme state of hyper-excitability or mobility—a state of "erethism," as it is called; and in this state slight causes of irritation which would be innocuous in a condition of stability set up the muscular motor spasm of laryngismus, tetany, or general convulsions. It is my object in this lecture to demonstrate as clearly as I can in what the essence of this predisposing constitutional state consists, in order that the principles upon which these affections must be treated may be fully recognised and understood; that I may warn you against the erroneous practice which widely prevails, and enforce safe and wise treatment of these common and serious disorders, with which in the course of your career you will be frequently called upon to deal.

Let me illustrate the clinical features of the three phases of spasmodic motor disturbance by one or two examples, and first a case of simple laryngismus stridulus.

Mrs. L——'s child, a boy of one year and seven months, was brought to me in December 1883, suffering from frequently recurring attacks of spasm of the glottis, from which it had suffered for the past six months. At first the seizures were merely occasional crowing inspirations, then after a time more severe; the breath stopped until the child became black in the face and was almost suffocated. Sometimes these attacks recurred every half-hour, the child waking up in the night with them; there was always a severe one on first waking in the morning, but the most alarming seizures oc-

[1] Tetany must be distinguished from idiopathic tetanus; indeed, there is little difficulty in the diagnosis. The fact that in the one case—tetanus—the contractions commence in the jaws and the muscles of expression, extend to the trunk, and only slowly and at last to the extremities, while in the other—tetany—the contractions commence in the extremities, and only extend to the trunk in rare cases afterwards, and seldom occur in the extremities and trunk simultaneously, serves to distinguish the two; moreover, the peculiar form of the contraction of the hands and feet is in itself pathognomonic—i.e., tetanoid contractions as distinguished from tetanic.

Digitized by Google

curred during the day, when the child was excited by laughter or vexation or crying. The child was extremely rickety, the forehead prominent, the fontanelle widely opened, the ribs beaded, and the wrists enlarged, but the long bones were not curved. It had great perspiration of the head at night; frequent diarrhœa; the muscles were soft and flabby; it could not walk; it had two teeth only, whereas at this age it should have had at least ten or twelve. There was no tetany or spasm; the thumbs were not drawn in, nor the toes flexed. The child had frequent attacks of crowing inspiration as I examined it. The explanation of the rickety condition was given by the history. It was kept at the breast until thirteen months old; latterly the mother had very little milk for it, and could give it the breast twice a day only. In addition to this it had nothing but nursery biscuits—no cows' milk, no beef-tea. After it was weaned, at thirteen months, it had a pint of cows' milk, Osborne biscuits, bread, and gravy. It had frequent diarrhœa. Here was a child, then, brought up on insufficient animal food; the imperfect nutrition was aggravated by frequent diarrhœa, hence nervous instability. A source of irritation increasing the motor nerve excitability was partly the intestinal catarrh, partly perhaps the irritation of teeth slowly making their way through the gums. The immediate cause of each spasm was the emotional excitement of laughter, or crying, or a breath of cold air. The invariable attack on waking was probably set up by the crying a child indulges in so often then, or the greater activity of the reflex function on the waking state. The treatment consisted in giving four grains of bromide of potassium with one grain of chloral every six hours, to relieve the spasm. During the attack cold water was directed to be dashed in the face, or a hot sponge to be applied to the throat. To improve nutrition and remove the predisposing cause of the convulsive seizures, two ounces of raw meat pulp and wheat flour with milk; this to be the sole diet. The baby was to be kept quiet—not played with, crossed, excited, or exposed to a stream of cold air. The child took the food well; the attacks at once grew fewer and less severe, coming on only on waking or under special excitement. The treatment by chloral and bromide was omitted for a time by the parents, with the result of a return of laryngismus and two severe general convulsions. After this warning the treatment was steadily continued, and the child got well without further relapse.

In the case I have related there was no tetany, but larnygismus with general convulsions. In the next case the laryngismus was accompanied by the tetanoid condition, but there were no general convulsions.

In December, 1883, I saw in consultation with Dr. —— a child of eleven months—a thin, miserable, white-faced child, with flabby muscles, projecting forehead, widely open fontanelle, pigeon breast, beaded ribs, and enlarged ends of the long bones. It had no teeth; at this age it should have had four or five at least. It had, in fact, all the signs of well-marked rickets. It had had repeated attacks of sickness and constant diarrhœa, no food seeming to agree with it. It was anæmic, chill, its temperature subnormal. I was asked to see it, however, chiefly on account of attacks of spasm of the glottis. These were occasionally so severe and prolonged as to bring the child to the verge of suffocation. They were brought on by the smallest excitement, but were most intense on first waking in the morning, or when induced by angry crying or by laughter—a feature of the preceding case, and I think universal in this disorder. On examining the child more minutely, the thumbs were seen to be tightly drawn in to the palm, which was arched longitudinally, the fingers adducted and overlapping each other—the typical so-called "accoucheur's hand" of tetany. The feet were arched and the toes flexed. The dorsum of the foot was much swollen, as if dropsical, but there was no actual œdema, the swelling being due probably to pressure of contracting muscles, not sufficient to produce effusion, acting just as a tight bandage does. The child was constantly crying with the pain of this cramp when the spasm was most intense. Twitching of the orbicularis and levator anguli oris could be induced by scratching the skin over the pes anserinus. The attacks of laryngismus had been increasing in intensity. The family history of the patient was remarkable and highly significant. There had been five children born alive, all strong, plump, and apparently healthy; yet of these five three died. The first had general convulsions at three months, and died in an attack of laryngismus at six months. The second died at six months and a half of diarrhœa and wasting; no laryngismus or convulsions. The third is still alive and fairly well, but she was weakly as an infant, and had two convulsions when teething. The fourth had "croup" when four months old, and died at the age of a year and ten months from general convulsions. The fifth was the youngest, who came under my observation in the condition I have described. So that four out of the five children had convulsive seizures, and the one who escaped convulsions had diarrhœa and atrophy. What is the explanation of this remarkable predisposition to convulsions. Was it an inherited tendency? a congenital nervous hyper-excitability? I think not. The tendency had been acquired—developed by defective nutrition. The explanation lay in the fact that all these children had been brought up by hand. The mother, closely engaged in business, could not give time to suckle her children. They were fed chiefly on corn flour, infants' food made without milk, and arrowroot, with hardly any milk, for cows' milk disagreed with all and caused vomiting and diarrhœa. No other animal food was given to make up for this. The only exception was the little patient. The parents rising in circumstances, the mother was able to give time to nurse the youngest baby, but she found she had little milk to give. So this, too, had corn flour and all kinds of things in the shape of bread-and-butter and farinaceous food. Its appetite was ravenous. The bowels were always loose, and it often had sickness. I advised that for the immediate relief of the laryngeal spasm half a grain of chloral and four grains of bromide should be given every four hours, and that the diet should be changed to one of animal food chiefly, with abundant nitrogenous matter; two ounces of raw meat, boiled milk diluted with one-third water, and thickened with entire wheat flour thoroughly boiled; with this, half a teaspoonful of brandy in a tablespoonful of food every four hours—a valuable assistance to circulation in these chilled, feeble children, and, moreover, a most useful nervous sedative in early life. The fits at once declined both in frequency and severity, and the tetanoid spasm of the hands and feet gradually relaxed. When I saw the patient again, in a week's time, the thumbs and toes were flexed, but the palms of the hands and soles of the feet were no longer arched or rigid. She improved steadily, and escaped convulsions; the attacks of laryngismus declined to two or three a week, and then not severe, instead of ten or twelve a day as at first. Then there was a relapse, when the bromide and chloral were stopped, but the laryngismus quickly subsided, and there were no more seizures. Cod-liver oil and lacto-phosphate of lime were given; and when seen six months afterwards, the child was stout, hard-fleshed, and robust in health, and had got five teeth (at one year and five months).

It is very curious and instructive to compare tetany in a child with what is called tetany in an adult. A case of this latter kind came under my care at St. Mary's Hospital in the spring of 1884. The patient was a thin, ill-nourished, anæmic girl of seventeen years of age. Her condition was briefly this. Both wrists were flexed, the hand being drawn towards the ulnar side, the thumbs firmly adducted and drawn across the palm of the hand; the fingers were partly flexed at the metacarpo-phalangeal joints, and slightly flexed at the phalangeal joints. Thus the hand became narrowed into the characteristic conical form.[2] Both hands were affected, the left being rather worse than the right. There was pain in the wrists and over the metacarpo-phalangeal joints. The skin over them was exquisitely tender and red. There was hyperæsthesia generally of the back of the hand and the ulnar side of the forearm. Any attempt to forcibly extend the fingers caused intense suffering. The lower limbs were free from contractions, yet as the patient sat up in bed to have her chest examined cramp came on suddenly in the right leg. The foot was forcibly extended by the spasmodic contraction of the calf muscles, the pain causing her to cry out sharply. When the patient resumed the recumbent posture the cramp instantly ceased. It was found, moreover, that no spasm was brought on if the patient kept her legs hanging down over the side of the bed when she sat up, or by walking a step or two. So that the spasm was clearly produced, not by the calf muscles being brought into active contraction, but by passive stretching of them.

[2] This form of contraction of the hand appears to be due to (1) the action of the adductor pollicis and flexor brevis pollicis, (2) palmar interossei hollowing the palm, (3) dorsal interossei causing separation of the fingers as attack passes off. All supplied by ulnar nerve. (Abercrombie: Tetany in Children, p. 16.)

Digitized by Google

Generally there was observed to be hyperæmia wherever there had been pressure—as over the patella where the bedclothes rested, over the spines of the scapulæ, and at the tops of the elbows. The tache cérébrale was readily produced. No fibrillar contractions of the orbicularis palpebrarum, or levator alæ nasi, or levator anguli oris could be induced by scratching the skin over the pes anserinus, as observed in severe cases in children. We made out that the contractions had commenced two days before, when the right hand began to feel stiff. On the next morning when she woke it was rigid, with the thumb drawn in as described, and great pain localised about the styloid process of the ulna. The left hand remained unaffected until the following morning, and soon became in the same state as the right. But although the tetanoid spasms had arisen two days before, they were by no means the commencement of the illness. The cramps were merely the sequel and outcome of previous disorder. The girl had been ill three weeks. She had had pyrexia and constant diarrhœa. An elder sister had just recovered from typhoid fever; another sister was down with it. The patient's temperature was 100·5°; pulse 120; tongue red; spleen enlarged and tender; no spots; stools not distinctive. But there was no doubt the girl was just recovering from a moderate attack of typhoid fever. In her history the following noteworthy facts appeared: In infancy she had convulsions when teething, and had been especially liable to croup and bronchitis. When twelve years old she had chorea. At twenty she was a surgical in-patient at St. Mary's Hospital with abscess in the side from necrosis of a rib, and had contraction of the muscles of the left arm, with pain lasting only twenty-four hours. Six other children, her brothers and sisters, had died, four of consumption, one of infantile convulsions, and one of bronchitis. Ten grains of chloral were ordered every four hours. In three days the tonic spasm had disappeared, stiffness and numbness alone remaining for a fortnight longer. For six weeks, however, cramps could be produced in the legs by forcible flexion of the ankle-joints. But the spasm could never even at first be produced by pressure on the brachial artery severe enough to blanch the limb, which Trousseau affirmed to be a distinctive feature of tetany. At the end of the six weeks she was well.

I think it is clear that the tetany in this case was identical with the tetany in the child. The spasm of the extremities in each was the typical contraction of tetany. The chief difference lay in the absence of facial irritability and of laryngeal spasm in the young woman—features of the disorder so characteristic in a young child. The presence of these special signs in infancy is probably due to the greater reflex nervous excitability notable in young children. If you toss a perfectly healthy baby into the air it crows, catches its breath—i.e., has slight laryngismus or spasm of the glottis. Some children, too, who are strong and healthy in every way apparently, get spasm of the glottis when in a violent fit of passion. The comparison of these cases of tetanoid spasm is interesting, and the question of their identity important, because it throws light upon the causation. I lay stress upon it on account of the bearing it has upon the pathology and treatment of the disease, as I shall show shortly, and also because it has been suggested that the tetany of children is a different affection from that described by Trousseau and others who had followed his lead in this matter.[3] Trousseau appears to have drawn his description of the disease chiefly from adults, although he mentions tetany as occurring frequently in infancy. Now the disorder as we see it in this country so commonly in children undoubtedly does not correspond absolutely with the original description. Trousseau laid stress upon the intermittent character of the spasms, and upon their being excited afresh, at will, by pressure "over principal nerve trunks, or over bloodvessels so as to impede the venous or arterial circulation." But in the case of the young woman these special characters were wanting. The spasms were not intermittent, and could not be reinduced at will by pressure over nerve or vessels; corresponding thus exactly with the case of the child, and agreeable to the observations of Henoch and Abercrombie in children. I have never seen a case in which the intermission of the contractions was complete. There is always variation in the degree and intensity of contraction, partial remissions, and exacerbations, but no absolute cessation, often for weeks. So that in all cases of children, and in the only adult which I have examined with regard to these points, these two symptoms, so prominent in Trousseau's picture—viz., the intermittent character of the spasm and its reinduction at will by pressure on nerve trunks or vessels,—have been altogether wanting. You will remember, however, that in the case of the young woman spasm of the calf muscles was at once produced by stretching, and it is significant that in children Dr. Abercrombie noted that muscles became more rigid on handling. It is possible, I think, that this phenomenon of hyper-excitability on pressure of muscle or stretching of it may have given rise to the impression that the spasm was excited by pressure on nerve or vessels, when it was in reality due to the stimulation of rough handling or stretching of muscle.

Another curious point with regard to the history of tetany is the fact before mentioned, that it has been described chiefly in relation to its occurrence in adults, whereas it is far more common in children. Of the seven cases given by Trousseau six were in adults, one only in a child. Of twelve cases I find in the medical journals (chiefly about 1870, when the subject cropped up, I suppose in consequence of the publication of Trousseau's Lectures by the Sydenham Society), two only were in children. Yet my friend and colleague Dr. Abercrombie, who has given the most complete account of the disorder in children in one year, met with no less than fourteen cases in children in this hospital. I have seen a very large number of cases in children, and only three or four in adults in the whole of my experience in this hospital, in a large general hospital, and in private. The fact is that, in children, this condition, when not extreme enough to be painful or obtrusive, is constantly disregarded because it occurs in connexion with laryngismus stridulus and convulsions. The minor is overshadowed by the major symptom, whereas in adults tetanoid contraction is the most prominent feature. Yet the peculiar spasm of hands and feet has been frequently described by authors, under the name of carpo-pedal contractions, as one of the symptoms accompanying laryngismus. Dr. Ley, Dr. West, Dr. Hillier, Meigs, and Pepper so describe it. The first person to identify these carpo-pedal contractions with tetany was Dr. Abercrombie, to whose excellent paper on the subject I refer you for much useful information.[4]

(To be concluded.)

[3] Henoch, for example, speaking of this condition, which he terms the idiopathic contractures of childhood, says: "This affection is classed with tetany by many, but in my opinion it is well to separate the two diseases entirely. I have never been able to detect the symptoms regarded by Trousseau as characteristic—viz., production of the contractures by pressure on the artery supplying the affected limb—in idiopathic contractures of children." Dr. Abercrombie, for similar reasons, expresses doubts as to the identity of the tetany of children with Trousseau's disease.

Lectures ON INJURIES OF NERVES.

Delivered at the Royal College of Surgeons,

By ANTHONY A. BOWLBY, F.R.C.S. Eng.,

SURGICAL REGISTRAR AND DEMONSTRATOR OF SURGICAL PATHOLOGY AT ST. BARTHOLOMEW'S HOSPITAL, HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS.

LECTURE I.

(Concluded from page 865.)

Union by first intention.—I have already said that the usual result of nerve section is degeneration of the entire peripheral end, and the question at once arises whether such a degeneration is invariable, or whether union by first intention, independently of such degeneration, can occur. As regards the fowl, Glück has very clearly shown that if the cut ends of a divided nerve are carefully sutured, degeneration may be entirely prevented; and although other experimenters disagree with him, in my opinion his conclusions are warranted. It is of course quite another question whether union by first intention occurs in man, for it must be clearly kept in mind that the results of experiments on the nerves of animals cannot be directly

Digitized by Google

transferred to man. The subject is one on which there has been much controversy, but I may say at once that from clinical observations I have no doubt of the possibility of primary union, although I think it is certainly very rare, and in support of my opinions will quote the following two cases.

H. H——, aged twenty-three, was admitted into St. Bartholomew's Hospital on Nov. 20th, 1881. He had fallen with outstretched hands on to some sheets of loose glass a few minutes before arriving at the hospital. On examination I found a large lacerated wound about an inch above the palmar surface of the right wrist, a flap of skin and muscle being turned downwards towards the palm of the hand. The whole of the flexor tendons of the wrist and fingers, except the flexor carpi ulnaris and the innermost tendon of the flexor sublimis digitorum, were divided. A small piece of bone was cut out of the radius, and the pronator quadratus was torn. The radial and interosseous arteries bled freely, and were tied; the arteria comes nervi mediani, which was very large, was similarly treated. The median nerve had been divided in two places, and the intervening portion of it, nearly an inch in length, lay loose in the wound, and was accordingly removed. I then drew down and stretched the upper end as forcibly as possible, and sutured it to the lower portion with carbolised catgut, the cut surfaces being brought into contact with some difficulty after extreme flexion of the wrist. As many tendons as possible were similarly fixed, and the wound dressed with carbolised oil, the hand being steadied in a position of flexion by means of a splint.—Nov. 21st: Much pain in the hand; no sensation whatever in the parts supplied by the median. Temperature 103°.—22nd: The edges of the skin have sloughed, but the deeper parts look healthy.—Dec. 1st: Sensation has been tested daily, but this morning, for the first time, he can tell which finger is pricked with a pin. No pain. A good deal of the wound has healed, and the part is granulating healthily.—3rd: With his eyes blindfolded he can now tell with certainty which finger is touched with the handle of a pen; the prick of a pin causes pain.—7th: Sensation in the thumb, index, and middle fingers is nearly perfect. He can feel the slightest touch, and can localise it accurately. Is fully sensitive to the prick of a pin, and can move the fingers slightly.—16th: Has much improved in the power of flexion; can thoroughly oppose the thumb and pick up a pin; says he has still a slight sensation of numbness; the fingers are all quite warm and fully sensitive to all stimuli.—24th: The wound has healed except for a very slight ulceration opposite the seat of injury to the radius; he says that, except for some stiffness in the fingers, one hand feels much the same as the other. Has increased power of movement in the fingers and thumb.—Eight months later this patient came to show himself at the hospital. He could not quite bend the fingers into the palm, owing to the adhesions of the tendons to the scar; otherwise there was no difference between the two hands, and the man said he could work and feel as well with one as the other.

I am indebted to Mr. Menzies for the details of the following case, which appears to me to be of unusual interest, alike from the care with which it is recorded and the rapidity with which the functions of the injured nerve were restored.

Primary suture of the median nerve, with union by first intention.—Jas. W——, aged fifteen, was admitted to the West London Hospital on Nov. 29th, 1884, having fallen on a glass bottle and cut his wrist. On examination there was found to be an incised wound an inch and a half long on the anterior aspect of the right wrist. The tendon of the palmaris longus was seen to be divided. The median nerve was completely divided. There was hæmorrhage from the arteria comes nervi mediani, and the patient had complete anæsthesia over the part supplied by the median nerve. The ends of the nerve were exposed and sutured with three catgut stitches passing through the trunk itself.—Nov. 30th: Patient had a good night, but complains of pain.—Dec. 1st: Wound dressed. He has tactile sensation, and localises accurately in the parts which were previously anæsthetic, with the exception of the last two phalanges of the index finger. The prick of a pin causes pain. He can distinguish the points of two pins one inch apart. Sense of temperature is uncertain, especially that of cold.—6th: Wound healing by granulation. Sensation is fully established to all forms of stimuli. He can appreciate the points of two pins half an inch apart, except on the index finger.—8th: Sensation returned in the index finger.—20th: The wound has healed. Sensation is equal to that of the other hand to all stimuli.—Jan. 20th, 1885: He uses the hand quite well; he says it is as good as it was before the injury.—July 20th, 1885: The hand differs in no way from that of the other side; the muscles are quite natural, but they do not react to either faradism or galvanism.

As to the actual lesion, and the rapidity of the subsequent recovery in the first case, there can be no room for doubt, for the patient was seen both at the time of the accident and during his convalescence by many competent observers, and the conditions I have described were frequently verified. The case under the care of Mr. Menzies is, again, in my opinion, quite undoubtedly one in which primary union occurred. In no other way than by actual union of the previously divided fibres is it possible to explain the preservation of such perfect sense of touch, pain, and temperature, and above all of muscular power. As to the completeness and rapidity of the cure the patient himself bore the strongest testimony, insisting that his hand was not numbed for more than about a day, and that it was "quite as good as the other in three weeks," notwithstanding that there had been a considerable wound. In other cases that I have observed there has been noticed a rapid restoration of function after primary suture of various nerves, leading one to believe that some fibres at least had undergone primary union; but the cases already quoted are sufficient for my present purpose—namely, to establish the fact that "primary union" of recently divided nerves, without any antecedent degeneration, is quite possible in man. For although up to the present no case has been recorded in which a microscopic examination could be made of the nerve during the process of repair, yet the complete return of sensation and of motion is a sufficient proof of the reality of primary union. Supposing that in any given case primary union does not occur, the length of time required for the restoration of the continuity of the nerve trunk is very variable. Paget considers that a year or more is requisite. Létiévant observed cases at the end of the nineteenth and fourteenth months respectively. The time required will necessarily depend on many circumstances. If the ends are far apart, if the wound sloughs, if a large quantity of dense cicatricial tissue intervenes, and if the cut nerve contracts adhesions to the surrounding muscles and tendons, union will be long delayed. In connexion with this question the following two cases are of interest: the first being an example of failure of primary union, due probably to separation of the cut ends, followed by subsequent regeneration; the second showing very plainly that, even when the best contact is maintained, primary union may be interfered with by erysipelas and sloughing.

Mary Ann P——, aged nine years, was admitted into St. Bartholomew's Hospital in October, 1879, having sustained a deep cut above the wrist-joint on the palmar surface. There was complete loss of sensation and motion in the parts supplied by the median nerve, but the cut ends could not be found. A few weeks later the patient was discharged unimproved and with some wasting of the muscles of the ball of the thumb. On July 24th, 1882, I had an opportunity of examining the hand and found it in the following condition:—Scar neither painful nor tender. Hand well nourished and plump, not at all atrophied. Fingers straight; can bend them well, but does not make a very good fist. Movements of thumb quite normal. Sensation perfect. No trophic changes. Suffers slight pain in the hand in cold weather. Her mother says that feeling did not begin to return till a year after the child left the hospital, but that since then motion and sensation have steadily improved.

R. W——, aged forty-four, was admitted into St. Bartholomew's Hospital on July 6th, 1882, on account of a wound on the inner side of the upper arm, which divided the biceps and a part of the median nerve. As the divided portions of the nerve tended to separate from each other, catgut sutures were inserted and the ends drawn together; the muscle was treated in a similar manner. On the 11th I found the wound suppurating, and the patient complaining of a sensation of numbness in all his fingers. The sensory condition was as follows:—Thumb: Tactile sensation impaired over the distal phalanx, both front and back; also sensations of pain and temperature; no place, however, is quite anæsthetic. Proximal phalanx normal. Index finger: No sensation of touch, pain, or temperature over the whole palmar surface,

Digitized by Google

or the dorsal surface of the last phalanx and half the second. Middle finger: No sensation of touch or temperature, but firm pressure with a pin at the tip causes pain, the seat of which he cannot localise; this statement refers to the palmar surface, the back of the finger being in a similar condition to that of the index. The fourth and fifth fingers have their normal sensibilities both back and front, also the entire palm and back of the hand. The movements of all the fingers are unimpaired, but the power to oppose the thumb is very deficient. On July 15th erysipelas of the arm supervened; there was no improvement in the nervous symptoms; no trophic disturbances. The erysipelas lasted some time, and no improvement was present until Aug. 19th, at which time he was able to distinguish two points of a pair of compasses a quarter of an inch apart on the dorsal surface of the second phalanges, and could localise the touch of a pencil except at the tips of the fingers on the palmar surface. At the time I made this note I had not seen the patient for ten days, so am unable to fix the exact date at which sensation commenced to return. A few days later the patient left the hospital, and did not show himself again till October 27th, when he exhibited the following condition: Forearm slightly wasted, and feels firm and hard; the range of supination is limited, apparently by the contraction of the pronator radii teres. Movements of fingers good; ball of thumb much wasted. He has now no power of opposition, the movements of the thumb having deteriorated since he was last seen. Trophic: No other trophic disturbances, but the fingers are cold and blue. Sensation—Thumb: Tactile, thermic, and pain sensations all present, and but little, if at all, impaired. Index: Can localise well all over, but sensation is impaired at the tip; sensation of temperature good. Middle: In much the same condition as index, but the skin over the third phalanx is more anæsthetic. He was now ordered to be galvanised twice a week, and to employ friction to the whole forearm and hand, with a mixture of equal parts of lin. saponis and lin. camph., also to use the forearm as much as possible, and to keep it warm.—Dec. 8th: Further improvement in both motion and sensation. Has returned to his work as a lamp-cleaner on the railway.—Aug. 9th, 1883: Sensation quite perfect everywhere, except in the index and middle fingers at the tips. Even here it is scarcely at all impaired, merely amounting to a slight loss of acuteness. Still some wasting of thumb muscles, but he has fair voluntary power in them. No reaction to electricity. Nails, skin, &c., normal.—March 26th, 1884: Sensation perfect. Muscles quite regenerated, being as large and strong as those of the other hand. All the muscles supplied by the median react to faradism, though as yet only feebly.

In the foregoing case it will be seen that although only part of the nerve was divided and good apposition maintained, yet a year and nine months elapsed before function was completely restored, and there can be little doubt that this delay must be attributed to the erysipelas, which prevented healing by first intention. I may also take the present opportunity of expressing my very firm opinion that the commonly accepted doctrine that partial section or wound of a nerve trunk is more dangerous, and more likely to lead to complications than complete section is quite erroneous. I have no doubt at all that, on the other hand, the amount of trouble is directly proportionate to the amount of nerve fibres divided, and have arrived at this conclusion after a clinical experience of many cases, both of partial and complete section.

The influence that the amount of nerve removed exercises on the length of time requisite for repair is well instanced by experiments on animals recorded by Létiévant. "After a simple section, the reunion of the ends by a cicatrix and the re-establishment of the functions requires three or four months, and this ought to be considered a good result. After resection of a centimetre, the same time is necessary. If more than a centimetre, five, six, twelve months, or more. After resection of more than three centimetres, the ends are only united by fibrous tissue, if at all."

Hill[1] gives the following as a result of experiments on dogs and rabbits:—Simple section: restoration in two, three, or four weeks. Excision of one-eighth of an inch: restoration in two, three, or four months. Excision of half an inch of the sciatic in a dog: restoration in four months. Considering the favourable results obtained by Glück by suture of the two ends after resection of a portion of nerve and the rapid repair in one of the cases I have related above, it is most probable that it is the distance of the divided ends from each other rather than the actual loss of nerve that influences the time required for reunion.

That the cut ends of a divided nerve can unite, even after excision of a considerable portion, is sufficiently proved by the case I have already described. That partial reunion may occur when the ends are widely separated has been shown by Mitchell. Three such cases are recorded by this author and Bertolet in the *American Journal of Medical Science* for 1876. In the first, both the musculo-spiral and median nerves united after excision of about an inch of each. In the second, after removal of an inch of one of the digital nerves, complete union was found in eighteen months. In the third, the radial nerve was repaired within ten months of excision of two inches of its trunk.

But although the preceding cases may fairly be adduced in evidence of the contention that it is possible for restoration of nerve continuity to occur after resection of portions of nerve trunks, it would be the gravest error to draw from such cases the conclusion that reunion occurs as a rule. And it is to be noticed that even in the instances above quoted the restoration of function was most imperfect. In very many cases, even of simple section, which are not treated, no union occurs in man—in far more, I think, than is generally believed; and I cannot agree with Mitchell that "the capacity of nerves to re-make their lost parts is almost invincible."[2] The records of surgery tell a very different tale, and one which is, unfortunately, much more unfavourable for the sufferers from nerve injury. The conclusion that repair of nerves is inevitable has been drawn from a return of pain in cases of neuralgia which have been treated with temporary success by the operation of neurotomy or neurectomy. Such conclusions are not warranted. Pain may return, and so may sensation, independently of nerve regeneration. The real truth is to be found in a study of cases of accidental nerve section which have not been treated, and in such, even where no bulk of nerve has been excised, my own experience and that of many other surgeons is entirely opposed to the conclusion that nerves whose ends are separated show any irresistible tendency to unite. If they unite at all, they do so in a most imperfect manner, and frequently there is no sign of repair. Although, as I have already said, the lower end of the nerve undergoes regeneration even though separated from the proximal portion, it seems probable that, after union by first intention has failed, the bringing together of the divided ends materially hastens the regenerative processes. For, as will subsequently be shown, a suturing together of nerve ends, which have been separated four, five, or six months, is sometimes followed by a very immediate and rapid return of function; in other cases, however, the process is slower, and in some it fails. In the cases which succeed it is evident that the otherwise very tardy process of regeneration is considerably accelerated by a union of the nerve with its centres of nutrition; and this, indeed, is rather what might be expected. Some French surgeons and physiologists have been unable to reconcile the plain facts taught by the results of secondary nerve suture with their theories as to how the injured nerves ought to behave. They argue that because in a given case of secondary suture no nerve fibres or axis cylinders can be found in the distal end at the time of operation, therefore any return of sensation which immediately or in the course of a few days follows operation and suture cannot be due to a re-establishment of the continuity of the injured trunk. Such objections as these will have no weight with anyone who is not hopelessly wedded to theory, for the facts in many of the cases which I shall mention in speaking of "treatment" are too plain to need any further advocacy on my part, and to them I would refer for confirmation of the statement that suture of nerves after many months separation may, and frequently does, result in a rapid restoration of function through a restoration of continuity of the divided axis cylinders.

THE PSYCHIC AND NERVOUS INFLUENCES IN DISEASES OF WOMEN.

BY HORATIO R. BIGELOW, M.D.

I WISH to emphasise with some force the distinction between the psychic or super-cerebral force and the chemico-molecular action, which is the expression of nervous energy, in the causation of many of the ills called gynæcological. The nervous energy may be directly objective, as alone concerned, without appealing to a higher agency; or it may be subjective, acting simply as a common carrier, transmitting its message of woe, and waiting for the ultimate order. The psychic exaltation or depression, generally speaking, merely calls forth a perversion of function; while the disturbed nervous energy, including trophic and vaso-motor changes, may occasion organic lesion. To regard the female pelvic organs as isolated points, without direct connexion with the whole bodily economy, is not a common heresy, but it is a danger that threatens, and gains ground the faster that gynæcologists absorb themselves with one branch of scientific medicine to the exclusion of all the others. He would be a poor physician who should forget the relationship of liver and stomach to cardiac disease, and he an equally unscientific gynæcologist who would castrate every hysterical woman. Surely the indefinable super-physical expression of a force that makes the physical weakling a hero in the battle of life; that radiates from itself a will so iron that even the strongest have been known to quail before it; that from a bed of suffering can create and originate; that can control a household or a community—surely such a power as this demands recognition in all of the processes concerning it. It makes no difference in the ultimate purpose of this paper whether we look upon the will as the *final* action of many separate cerebral departments—a desire or aversion sufficiently strong to generate action; or whether we look upon it as a material entity whose freedom is assured by the divine fingers that attune it,—the fact still remains that the psychic force, however manifested, must always demand consideration from the specialist. The autocracy of such a monarch cannot be disputed, and his messages, borne on the wings of his fleet-footed messengers—the nerves,—will set many an intelligent physician to patient thinking. All specialism is dangerous in proportion as it becomes exclusive or seeks to narrow a wide and general field of intelligence. No one can hope for success in any specialty unless he is intelligently instructed upon the salient features of other specialties. And perhaps in no other calling so largely as in gynæcology is it necessary to be acquainted with the subjective life of woman. What are her thoughts, her hopes, her aspirations? How largely is she given to introspection? How firmly and in what manner is her ideal building? Then we must know of her objective necessities in æsthetics and social graces, and train ourselves in the many little things that go largely into the make-up of womanly comfort, and which will gain the patient's confidence in the proportion in which we embody them in our actions. So much by way of preface. We now come to something practical, although after that has been said the necessities of the subject must drift us back again to theoretical reasoning.

The nerves with which the gynæcologist must concern himself are—the plexus solaris or cœliacus; the plexus mesentericus, superior and inferior; the plexus aorticus abdominalis; the plexus hypogastricus superior; the plexus spermaticus; and the plexus hypogastricus inferior, between the floor of the bladder and the rectum. From the cord (from the plexus lumbalis) we have the nervi ilio-hypogastrici, ilio-inguinales, genito-crurales (a favourite seat of neuralgic pain); the plexus and ganglion at the cervix (described by Frankenhauser and Jastrebow); the nuclei terminations in the unstriped muscle of the uterus (Frankenhauser); the ganglionic terminations in the mucous membrane, and the end bulbs in the clitoris and vagina. The vagina, uterus, Fallopian tube, and ovary are supplied by filaments from the inferior hypogastric plexuses. The muscles receive supply as follows: the levator ani and sphincter ani by the inferior hæmorrhoidal branch of the pudic, fourth and fifth sacral, and coccygeal nerves; the coccygeus by the fourth and fifth sacral and coccygeal nerves; the muscles of the perineum and clitoris by branches of the pudic nerve. These are they, then, which give rise to those immediate reflex neuroses with which the gynæcologist has to do. Other nerves there are, of equal importance, giving origin to reflex symptoms equally distressing, and with which he should make himself acquainted; for palpitation of the heart, nervous dyspepsia, spasmodic contraction of the gall-bladder, or migraine, will not disappear coincidently with the righting of a dislocated uterus, with the sewing up of a lacerated cervix, with the extirpation of an offending ovary, or with the healing of an endometritis.

In losing sight of constitutional causes as factors of local disease all special erudition and all clever handiwork will be in vain. Many ills to which women are liable are merely *symptoms*, and they will never cease their direful work until intelligence looks deeper and attacks the exciting cause. It will not be one particle of service to attack a retroverted uterus with pessaries (a refinement of torture and of unscientific deduction of this nineteenth century) in a highly nervous woman, whose trouble rests not with her womb, but with her "run down" condition generally. I will go a step further, and assert that rest, good diet and regular, electricity, massage, and Turkish bathing (when indicated), with wholesome psychic surroundings, will, in very many instances which receive nowadays only local attention, accomplish more permanent and real good than any special interference. Vastly more harm than good has resulted from the happy-go-lucky way of applying pessaries, and quite as much evil comes from the brusque way we have of relegating all womanly suffering to pelvic derangement, and then rushing blindly at that, irrespective of the shock we may occasion to a highly modest and sensitive woman. Liebermeister asserts that this *nervosität* is due to a disease of the grey substance of the brain which depends upon a derangement of the lower brain function, as contra-distinguished from the true disease of the brain, which is due to a disturbance of the higher psychic function. Convinced in my own mind that Liebermeister is right, I should seek to improve every detail of the woman's environment, subjective and objective, before resorting to local interference; of course I mean in those instances in which the local trouble is purely secondary. "Run down" women, women with all sorts of anomalous aches and pains, women given to morbid introspection although they *may* have some pelvic pathological condition, demand first constitutional handling, and we simply intensify every bad symptom by ambitious specialism. Rheinstaedter[1] says: "I have never yet done a castration for *nervosität*, and I intend never doing so in the future. How can we hope to cure a brain disease through castration? Why do we not castrate men for nervousness?" The radical operation of oöphorectomy in case of neurasthenic hysteria (and I mean by this an hysteria which is clearly due to nerve exhaustion) is *never* indicated, neither can it ever be indicated in pure neurasthenia. In pure hysteria it is only justifiable when the exciting cause can be clearly and absolutely located in the ovary beyond all question of a reasonable doubt, and even then it should never be thought of until we have exhausted all the means of conservative treatment which recent investigation has placed within our reach. It seems to me that the clear indications for so dangerous an operation are so very small as to be almost *nil*, and I am convinced that many cases on record so operated upon would have gone on to a wholesome recovery under strict conservative treatment, as we realise and recognise it to-day—a treatment that requires boundless patience both from patient and physician, but which accomplishes its purpose surely and almost insensibly to the woman, until she finds herself carrying out the daily duties of life as most women do, and with the same measure of comfort. A woman's mind has much to do with her general condition, and herein lies the secret of the rest treatment. With a mind at absolute rest, with no thought of the morrow to conjure up the fiend of ways and means, with a complete realisation of the *dolce far niente*, we have at hand a more potent medicine than any sent out from drug stores. And I know, because what I have seen I believe, that under such rational handling many gynæcological cases go on to recovery without any local interference. Of very especial value is rest treatment, because it enables the physician to discipline the disorganised will, and to bring it into harmonious relationship with the other bodily functions. Hysteria disappears at once under an organised, well-sustained moral discipline. The nervous condition,

[1] Praktische Grundzüge der Gynækologie. Berlin, 1886.

Digitized by Google

which is the underlying cause, is one of exaggeration, congestion, and exhaustion, and these all disappear upon proper hygienic observances, conjoined to will training. The weakened will itself is but part and parcel of the whole nervous disorganisation, and will regain its normal standard as soon as the other functions return to a physiological basis. The nerve-supply of the female pelvis is not a distinct and isolated department, but intimately connected with the whole nervous system. So that disorganised function anywhere, but the more especially in the brain and spinal cord, may transmit its influence to the ovary. If we admit the possibility of "maternal impressions" stamping themselves upon the fœtus in utero, we must also admit that certain states of consciousness can impress themselves upon and be felt within the uterus. This premiss seems reasonable by virtue of the direct connexion between the mucous membrane of the uterus and the chief mucous centres. Clinical evidence of the influence of the brain upon the uterus is ample. A prolonged unhealthy nervous influence would set up a correspondingly unhealthy action in the organ reached and affected by it. Not only directly through the filaments and ganglions, but also by its effect upon blood-supply, will any derangement of nervous function be sensibly appreciated by other and remote organs. Either congestion or anæmia may result from prolonged states of cerebral excitement or exhaustion. Arterial tension hinges largely upon states of consciousness, and menstruation, which is one of its expressions, is always regulated by the nervous condition of the woman. I am not at all sure but that many of the changes in the endometrium that occasion thickening, hyperplastic proliferation, tumour growths, and malignant hyperplasia of the uterine glands are due first to nervous influences, subsequent congestion, and generally altered blood-supply. If this be so, we should address ourselves first to a normal rehabilitation of nerve and bloodvessel, and then seek to eradicate any local condition which would interfere with such treatment. Gynæcology has handicapped itself with excess of detail, and, like all specialties, its field of vision is limited. The success of a few, who do little or nothing else, has created a surgical epidemic, and whole communities rush headlong into a *strom*, where experience is partially learned at the cost of hundreds of lives sacrificed. These habits of thought and medical crazes revolve in certain well-known cycles. Already there is the faint flutter that precedes the coming storm. We are on the eve of a change in gynæcological practice, in which the scalpel will be the bar sinister and conservatism the crest and crown of our special coat of arms. Define the limits of abdominal surgery to its narrowest confines, and then let those only practise it who are educated to it and who devote their lives to it; no others have the right to place a human life in jeopardy. I have said that there are countless instances on record, where special surgery has failed to relieve general symptoms, and of these ailments none is more common than neuralgia of the trigeminus nerve, or so-called migraine.[2] The cry of the trigeminus is the echo perhaps of the uterine wail, they both ache synchronously with the pathological pain of the central system, which is labouring to carry out its daily routine under unnatural effort. The migraine and the "pain in the side" (ovarian) are merely symptoms, and can be best reached, and only reached, so far as I know, by constitutional treatment. You will not cure the migraine by extirpating the ovary, and you will not cure the ovary-ache by resecting the trigeminus, even were one bold enough to attempt it. One operation is about as sensible as the other. Take the complex symptomatology of oöphoritis (a most vague term, rather a cloak of ignorance than the expression of scientific pathology), with its pain in the side, leg-ache, dyspepsia, intra-menstrual peritoneal pains, and spasmodic action of the gall-duct setting up an appearance of icterus. What are we going to do about it? The ovary is suffering no more as a primary cause than does the aching tooth of a pregnant woman act primarily. The tooth does not ache from the presence of a cavity, but from sympathy. Now, shall we turn the woman's stomach into an apothecary's shop, dosing her specifically for each disordered function, combining this with the routine local treatment; or shall we go to work and find out what makes the ovary ache, and then treat the cause? In a rare percentage of cases I will admit that the terminal filaments from the inferior hypogastric plexus within the ovary, have, for some reason unknown to us, taken on diseased action, and have so transmitted their plaint. But such instances are rare, and when they do occur there must be some reason for the nervous and vascular changes. That reason cannot rest within the ovary itself, but it does rest in the chemico-molecular changes in the vessels sustaining its life. It may be objected that the train of symptoms that I have cited belongs to catarrhal salpingitis, with enlargement of the ovary, but I only say that which I know, and that which I have seen I take as evidence of anything that I adduce. Simple tubal disease, non-specific in the nature of its discharge, *does not call for the operation of Hegar*. Gonorrhœal salpingitis, when recognised, can be treated first by dilating the tube with a catheter. If that fail, and the woman's condition is so unbearable that she demands it, then Hegar's operation is justifiable, but not until the full line of treatment which I have often suggested is first given a fair trial. There are a certain number of gynæcological cases which will always demand the skilled hand and clever brain of the surgeon; but the number is not as large as is generally supposed, while the surgeons multiply with wonderful rapidity. I am sure that before long our whole process of combating diseases of the endometrium will undergo radical change, for there cannot be inherent potentiality in the mucous membrane of the uterus to originate so many complex conditions. When we have once found out the true nature of this mucous membrane, when we know surely the *rôle* it plays in menstruation, we shall then arrive at a knowledge of the prophylaxis, pathoanatomy, and etiology of uterine myoma. Even now we are finding out that many uterine myomata will yield to conservative treatment which gynæcology until very lately maintained should be cut out.

Leipzig.

EXCISION OF THE LARYNX.

By W. GARDNER, M.D., C.M. GLAS.,
SURGEON TO THE ADELAIDE HOSPITAL, AND LECTURER ON SURGERY IN THE ADELAIDE UNIVERSITY.

JAMES M——, aged sixty, shoemaker, living in a small suburb of Adelaide, was sent to me by my friend Mr. Corbin as a probable case of malignant disease of the larynx, with a request that I would examine him, and do what I could to rid him of his trouble. On Oct. 9th, 1886, I admitted him to the Private Hospital. For the following notes of his previous history and present illness I am indebted to my assistant-surgeon in the Adelaide Hospital (Dr. Ainstey Giles).

"The patient has been a healthy man all his life, and has never suffered in any way except from an occasional cold. He has always been engaged in the same trade, and has not suffered from syphilis or been exposed to hardships of any kind. His father died at the age of eighty, and his mother at forty. He does not know the cause of death in either case. His grandmother (paternal) died at the age of ninety. There has been no disease of an hereditary nature in the family. Two years ago he lost his voice entirely, and it has never returned. Previously to losing his voice he suffered from no throat affection of any kind. The voice gradually became weaker, till at the end of about four months he could not speak above a whisper. He continued in this state until four months ago, when he began to experience a sharp gnawing pain over the larynx, for which he was treated in various ways, but without the least improvement in the conditions. He has had a long course of iodide of potassium, with no result. With the increase of pain he has been rapidly losing flesh, feeling very weak, and during the whole period (four months) has been unable to rest at night on account of the pain, which wakes him up continually. He never had any night sweats. He can take food fairly well, but has no appetite, and swallowing causes slight pain. There is no absolute aphonia."

On laryngoscopic examination both true vocal cords were found to be ulcerated away in nearly their entire length. Irregular white papillomatous nodules were projecting into the centre of the larynx from the sides immediately below the glottis. The false cords and the mucous membrane above were very much inflamed and bulged out by a solid growth underneath, more marked on the right side than on

Digitized by Google

the left. Arytenoid cartilages not swollen or abnormally red; posterior commissure not thickened. The epiglottis was quite free from the growth, and there was no sign of any disease above the larynx. There was nothing abnormal to be felt externally in the neck, and the glands were not enlarged. The larynx was quite free and movable, but some pain was caused when it was pressed between the fingers. A small piece of the growth was removed with laryngeal forceps and sent to Professor Watson, who very kindly examined it and pronounced it to be a "cornifying epithelioma." On examining the lungs the chest was seen to be barrel-shaped. All over the front and back of the right lung the percussion note was fairly resonant. Over the left lung hyper-resonance was observed. No increase in the vocal fremitus. Respiration harsher than normal all over the chest, and expiration prolonged—more marked on the right side than on the left. No râles, rhonchi, or accompanying sounds of any kind to be heard. Vocal resonance normal. Heart sounds normal. Pulse slow, full, and regular. Arteries not atheromatous. The urine contained neither sugar nor albumen.

On Oct. 12th, at 3.30 P.M., the following operation was performed. The patient having been put under the influence of chloroform, the whole anterior part of the larynx was exposed by making a free incision from the thyroid bone to a point immediately below the second ring of the trachea. The anterior jugular veins were tied in two places and divided between the ligatures, as they interfered with a free dissection. The muscles attached to the side of the thyroid cartilage were thoroughly separated as far back as possible, and the fascia attached to its upper edge was set free without dividing the thyro-hyoid membrane. The hæmorrhage was troublesome and very free, the bleeding from the crico-thyroid artery being very difficult to arrest. Every bleeding point was carefully ligatured, and pressure with hot sponges gradually reduced the oozing. I opened the trachea between the cricoid cartilage and its first ring and at once inserted a well-fitting tube, made of lead, which effectually prevented blood from entering the lung. A flexible rubber tube, about ten inches long, was attached to this, and the administration of chloroform was continued through it. Then, principally with the handle of my knife, I separated the larynx from the œsophagus, divided the superior cornu of the thyroid cartilage, cut through the thyro-hyoid membrane, and finally divided the superior and posterior attachments of the larynx, as close to the cartilages as possible, with a pair of scissors, the epiglottis being cut through at its base. The superior thyroid arteries bled profusely, but were at once caught and ligatured. The patient took the anæsthetic easily, bore the operation well, and showed no signs of collapse. As far as possible throughout the operation the parts were separated by working with the handle of the knife. All bleeding points were ligatured with chromicised Wallaby tendons, which make most excellent ligatures, being strong, safe, and easy to apply. The wound was dusted over with iodoform and covered with absorbent cotton-wool. The tube was securely tied in with tapes passed round the neck and under the axilla.—6.30 P.M.: Slight oozing of blood-stained saliva took place from above the tube.—8 P.M.: An enema of beef-tea and brandy administered, and carbolic acid spray used for five minutes in the room. Temperature 98°.—9.40 P.M.: one-sixth of a grain of morphia injected hypodermically.—12 P.M.: Enema of beef-tea and brandy given. Carbolic acid spray used in the room.

Oct. 13th.—Ordered an enema of beef-tea and brandy every four hours; carbolic spray also used in the room. Temperature 98·6°. Slept well through the night. Slight cough. Pulse 88; respiration 28. Some blood-stained saliva. Wound dressed with absorbent cotton-wool sprinkled with iodoform laid above and below the tube. A piece of carbolised gauze was placed over the orifice of the tube, and the patient raised to a sitting posture. No oozing from the wound. Chest sounds over bases of lungs normal. At 4 P.M. a small red rubber catheter was passed down the œsophagus from the wound in the throat, and through a glass funnel about a pint of milk and lime-water was allowed to flow into the stomach.—9.30 P.M.: Temperature 98·6°; pulse 84; respiration 28.

14th.—Feeding by the œsophageal tube was continued, and also enemata of beef-tea and brandy. The tube was not kept *in situ*, but was easily introduced each time that it was considered necessary to feed the patient. Temperature 98·4°; respiration 21; pulse 92. Skin cool and moist; no pain. Lungs resonant all over back and front; breath-sounds normal. Great quantities of saliva running from the wound. Wound dressed with iodoform and absorbent cotton-wool. Tube keeps in good position and causes no irritation.—3 P.M.: A pint of milk with brandy and lime-water passed into the stomach through the œsophageal tube, causing slight vomiting and some feeling of discomfort. Half the quantity was ordered to be given at a time for the future. Cough troublesome.—9 P.M.: Temperature 98·4°; pulse 84; respiration 22.

15th.—Slept well throughout the night; cough easier. Temperature 98°; pulse 80; respiration 24.—2.45 P.M.: Leaden tube replaced by a silver one of similar shape but rather larger calibre.—9 P.M.: Complains of thirst. Lemon-water given to rinse out the mouth.

16th.—Slept fairly well. Cough rather troublesome. A quantity of thick phlegm was expectorated. Temperature 98°; pulse 80; respiration 18. Wound almost healed above. Copious flow of saliva.

From this date to the 19th the treatment was just the same, and the temperature continued normal, with diminished cough and lessened expectoration of phlegm. The little finger was passed every other day upwards as far as the base of the epiglottis to keep the way open for the insertion of the upper tube of the artificial larynx afterwards. On Dec. 3rd the patient was discharged, and returned to his own home, wearing only the lower tube of an artificial apparatus which had been made for me from the woodcut in THE LANCET, as used by the late Dr. Foulis of Glasgow, and modified from Gussenbauer's original apparatus by Dr. Irvine. In this case, however, the straight tube could not be inserted, and I had the upper one altered so as to assimilate it to Gussenbauer's original apparatus.

On Jan. 17th, 1887, the man re-entered the Private Hospital, and, under chloroform, the upper wound was reopened sufficiently to admit the upper tube, and then the lower tube was passed through it, and the whole tied in with tapes round the neck. The reed used was made of platinum, and, although the note was rather trumpet-like, his words could be distinctly understood on his awakening from the anæsthetic. After the insertion of the upper tube liquids were found to run down whenever he drank, and recourse was had to the soft rubber tube, which was passed down the œsophagus several times a day for feeding purposes. Examination with the laryngoscope showed the silver tube appearing just below the epiglottis, which was very œdematous. Tannic acid spray was ordered, and no examination was made until the end of the month, when it was discovered that there was a small new growth on the anterior pillar of the fauces low down, with a small amount of glandular enlargement of the neck on the same side. As it was evident that the disease had returned, it was decided to remove the upper tube to prevent any irritation, and, as the epiglottis was not acting, to enable him to take food again by the mouth by allowing the upper wound to heal, which it did very rapidly, and on Feb. 5th, being able to take both liquids and solids well, he was sent home again. On the morning of Feb. 11th I again saw the patient, and the growth had increased markedly. He was wearing a tube which I had constructed of silver, like a tracheotomy tube, but with a more abrupt dip into the trachea. This he found exceedingly comfortable, and all he complained of was pain in the right ear. He seemed thoroughly well nourished, and expressed gratitude for the temporary relief afforded him.

Remarks.—This case is interesting as being only the third operated on in the British dominions in which the patient has lived more than four months. The others were operated on by the late Dr. Foulis and Dr. Newman, both of Glasgow. It is not encouraging to find recurrence so rapid after recovery from so formidable an operation, especially as there was nothing to suggest that the disease had passed beyond the confines of the larynx. Of the eighty-three cases which Dr. J. Baratoux has collected, death occurred in half of them before the fourth month. I would draw attention (1) to the ease with which the blood can be kept out of the trachea by the rectangular tube made the full diameter of the normal larynx, and inserted immediately after the division of the trachea, thus lessening greatly the risk of septic pneumonia; (2) that the "hanging head" position is also of immense advantage; and (3) that it is probable, in the great majority of cases, that Gussenbauer's original artificial larynx is the best, although the straight upper tube seems to have suited the late Dr. Foulis' case. In the method of operating I am indebted to the papers of Dr. Foulis and Dr. Newman, and

Digitized by Google

after consideration I decided to adopt the method of the latter, as being probably the easier and better plan. The interesting discussion at the Clinical Society has induced me to forward my case as a contribution to the subject. If Mr. Butlin's opinion that "complete excision of the larynx for carcinoma should be practised only in very rare instances, as the mortality from the operation is large and the prospect of cure small," is ever to be altered, it must be by attempts to ensure an earlier diagnosis, and in the meantime I indulge the hope that this may be accomplished.

Adelaide, South Australia.

ON THE

ADMINISTRATION OF CARBONATE OF LIME AS A MEANS OF ARRESTING THE GROWTH OF CANCEROUS TUMOURS.

BY PETER HOOD, M.D.

NEARLY twenty years ago THE LANCET published a communication from me on the value of carbonate of lime in the form of calcined oyster-shells as a means of arresting the growth of cancerous tumours, and I am anxious once more to call attention to the subject, and to urge upon those who possess the necessary facilities that a more extended trial should be given to this agent than it appears yet to have received. My own opportunities of employing it in suitable cases have not been large, but the results which I have witnessed have been sufficiently remarkable to justify me in seeking for them a more extended publicity.

In the paper referred to I related in detail the case of a lady nearly eighty years of age who was the subject of schirrus of the breast, and in whom the growth sloughed away and left a healthy surface after a course of carbonate of lime, administered in accordance with a recipe which was current in her family. She manufactured her carbonate of lime by baking oyster-shells in an oven and then scraping off the calcined white lining of the concave shell. The substance thus obtained was reduced to powder, and as much as would lie on a shilling was taken once or twice a day in a little warm water or tea. It was said that perseverance for at least three months was necessary before any good result was to be expected. I presume that the powder would be almost pure carbonate of lime, but it might possibly contain a small admixture of iodine.

The immediate cause of the publication of my paper was a conversation with Mr. (now Sir) Spencer Wells, to whom I related the particulars of the case above mentioned, and of one or two others which had fallen under my notice, and who suggested that the beneficial action of the powder might be due to the lime which it contained. He told me that he had used lime largely in the treatment of uterine fibroids and other tumours, and that he was convinced that processes of atrophy and calcification resembling the spontaneous change or degeneration sometimes observed in them were often produced or promoted by its action. He added that he believed the change commenced in the coats of the arteries by which the tumours were supplied with blood, and that these coats underwent first an atheromatous and subsequently a calcareous degeneration, in either case with a diminution of the calibre of the vessel and a lessened capacity for the conveyance of blood.

After the appearance of my paper I was applied to by several persons with an inquiry as to whether their cases were suitable for the employment of the remedy; but in most of these instances I subsequently found that it had been taken for only a few weeks, and then abandoned because no result was apparent. I should not hope for manifest benefit in any instance under three months of persistent treatment. A notable exception to the ordinary want of perseverance was furnished by the wife of a physician practising at Reading. This lady was the subject of a well-marked schirrus of the breast, which I had myself an opportunity of examining. After a fair and persistent trial of the calcined shell powder for three months, her husband reported to me that "the tumour had ceased growing and that she suffered no pain." She continued to take the powder for several months longer, and for several years her husband paid me an annual visit, always giving the same account, "that his wife never suffered any inconvenience or pain from her disease, the progress of which had been stopped."

The ordinary history of true cancer is such a dismal record of failure, that I think even a few instances in which benefit has been derived from a harmless remedy should encourage the profession to make trial of it in all suitable cases. It would probably be inexpedient, generally speaking, to disclose the nature of the medicine, and the public mind is by degrees becoming permeated by the knowledge that many important medical actions can only be gradually produced. We have no difficulty in inducing patients to submit to prolonged courses of mercury in the treatment of syphilis, and there is no reason why they should not do the same in a malady which, if possible, is even more formidable. Up to the present time the narratives of cures of cancer have been chiefly suggestive of errors of diagnosis, and no assurance of the value of any proposed remedy can be obtained until it has been used in a sufficient number of instances to exclude the possibility of such errors having been committed in the majority of them. Although the experience of Sir Spencer Wells with fibroids points to the probability of a beneficial action upon soft and vascular growths, those which I should myself select for the purpose of further investigation would be typical examples of breast schirrus, adherent tumours of stony hardness, attended by retraction of the nipple and lancinating pain. About the nature of such it would seldom be possible to entertain a doubt.

As an example of the uncertainty which may overhang the true characters of growths which do not present the symptoms above described, I may mention that I was once consulted by a lady living in the north of England, who had a swelling in her breast which had been pronounced to be cancer by her family medical attendant, and also by two consultants called in from the neighbouring county town. She was urged to submit to an operation, but, before consenting, she came to London for further advice. She paid separate visits to Sir James Paget, to the late Mr. Skey, and to me. I was the first whom she visited, and I gave an opinion that the tumour was a harmless one and might be let alone. Her second visit was to Mr. Skey, who said without hesitation that it was a cancer, and advised removal. Her third visit was to Sir James Paget, who said that the growth was innocent. It was let alone, and the patient has had no further trouble from it for twenty years.

Again, I was lately consulted about the case of a well-known nobleman, who had a soft growth in the front of his chest over the upper part of the sternum, which quickly attained a considerable size, and was pronounced to be malignant by eminent authorities. It disappeared entirely under a course of small doses of the perchloride of mercury.

It is therefore not in cases which admit of any reasonable doubt of their nature that I would desire to urge a trial of the lime powder upon the profession. There are hundreds of instances of unmistakable cancer in which an operation, if performed, may perhaps for a time diminish suffering or may prolong life, but in which it cannot afford any well-grounded hope of restoration to health. For all such I would say that the lime ought to be persistently and fairly tried. It can do no possible harm, it need not interfere with any remedies for the present relief of pain, its action can be referred to a perfectly intelligible and probable hypothesis, and it has been of unquestionable utility in a sufficient number of cases to warrant us in reposing some confidence in its use. We have a great hospital devoted to cancer, and cancer wards in others also; and I think the time has come when this simple means should be fairly tested by the profession. It is not long since we witnessed an extraordinary eagerness to try the Chian turpentine, which was so much extolled by Dr. Clay, and in support of which the *primâ-facie* case was nothing like so strong as that in favour of the remedy to which I desire once more to call attention.

Seymour-street, W.

ASSOCIATION OF SANITARY INSPECTORS. — On the 23rd ult., at a well-attended meeting of public sanitary inspectors at Liverpool, it was decided to form an association for the north-western district. A provisional committee was formed to give effect to this resolution, and Mr. A. Taylor, inspector of Wallasey, was appointed temporary secretary and treasurer.

DIFFUSED INNOMINATE ANEURYSM.

BY J. G. BLACKMAN, M.D. BRUX., M.R.C.S., &c.

THE great interest and importance attaching to aneurysmal disease of the innominate artery, and its comparative rarity, induce me to record the following case, which I think particularly shows the impossibility of diagnosing the actual limits of the disease in this class of cases, and the risk in operating lest the available vessels be atheromatous.

William W——, aged sixty, shipwright, first came under my care four years ago, suffering from hæmorrhoids. As he was losing a rather large quantity of blood after each stool, and was much weakened in consequence, I proposed their removal to him, to which procedure he assented. Upon examining his heart preliminary to the administration of an anæsthetic, a somewhat loud systolic bruit was heard over the aortic area. To be on the safe side it was decided to operate without anæsthesia, which was accordingly done, and the patient made a quick recovery.

He, however, shortly afterwards again consulted me, complaining of obscure pains in the chest and back, which he said quite unfitted him for his work; and in accordance with his wish the authorities of the dockyard granted his superannuation. On examining his chest again, I could discover nothing abnormal except the bruit previously mentioned, and the subjective symptoms seemed quite out of proportion to the objective. I was, however, able to afford him some relief by the administration of anodyne drugs, and after a time I quite lost sight of him. This respite was, however, not destined to last long, for in November, 1885, he once more came to me, this time complaining of a swelling in the neck in addition to his other troubles. On examination, I discovered a pulsating tumour, the size of a large walnut, situated immediately behind the right sterno-clavicular joint. He did not complain of much pain. The right radial pulse was full and strong, while the left was small and weak. The right carotid pulse was weakened. In spite of the anomalous condition of the radial pulses, I felt sure I had to deal with an innominate aneurysm, probably complicated with aortic disease. I saw him in consultation with several medical friends, who, with myself, deemed operative interference unadvisable, considering the probable general diseased condition of his arteries, and also the possibility of its being aortic. I prescribed a spare diet with absolute rest, and gave a mixture containing iodide of potassium with morphine. The second injunction he refused to obey, and persisted, in spite of repeated warnings, in taking long walks and occasionally doing a little gardening. Under these adverse circumstances the tumour steadily increased until about three months before his death, at which period it began suddenly to enlarge very rapidly, and at each visit I noticed a decided difference. The dimensions it attained are well shown in the accompanying woodcut, which is from a photograph taken a month before death by Mr. Newby, F.R.C.S. Eng. It will be noticed that the surface is very uneven, and appears, as it were, "pointing" in several places, one of which (marked A) became very thin and developed a black crust on its summit, which eventually came off leaving an ulcer, the base of which seemed to be entirely composed of cellular tissue. This condition caused me great anxiety, as it gave one the idea that the next pulsation must burst the apparently thin tissue. Fortunately this event did not happen, for although the ulcer spread to the size of a florin and bled to a trifling extent, it gradually became drier, and the poor fellow died from exhaustion, and in part possibly from suffocation, on Dec. 7th, 1886, having only taken to his bed during the last week of his long illness.

Necropsy.—The wall of the sac was of varying thickness, being at the most not more than from three-eighths to half an inch, and in some places was extremely thin. The arterial coats could not be distinguished, and there was scarcely any attempt at lamination. A small clot of fibrine was found in the interior, surrounded with dark, semi-coagulated blood. On tracing the sac, it was found to pass in all directions. To the outer side, it communicated with the right subclavian artery, and upwards with the carotid artery of the same side; whilst to the inner side it passed across the trachea, œsophagus, left carotid, and subclavian arteries. Downwards, it had passed over the clavicles and sternum, eroding the sternal ends of the former bones and the upper part of the first piece of the latter bone. Backwards, it had pressed upon and displaced both the trachea and the œsophagus. The aorta was found to be considerably dilated and atheromatous, the disease involving the whole of the arch and the commencement of the thoracic portion. On passing the finger along the interior of this vessel, one discovered the opening corresponding to the innominate artery, which communicated directly with the aneurysmal sac; the atheroma here appeared to be less marked. Passing the finger along still further, the openings of the left carotid and subclavian arteries could be made out, the former being a mere chink, whilst the latter was of natural size. Both openings were, however, rigid, and surrounded by atheromatous calcification, and gave the impression of being foramina in bone. The coats of both carotids and subclavians were more or less diseased. A further inspection was not permitted by the friends.

Portsmouth.

MALIGNANT DISEASE OF RIGHT LUNG AND POSTERIOR MEDIASTINUM, PRODUCING COMPLETE PARAPLEGIA.

BY FREDERICK J. SMITH, M.R.C.P., M.B. OXON.,
MEDICAL REGISTRAR TO THE LONDON HOSPITAL.

BY the kindness of Dr. H. G. Sutton, under whose care the patient was in hospital, I am enabled to publish the following case, which presents somewhat rare and peculiar features.

B. C——, aged forty-five, was admitted into the London Hospital on June 1st, 1886, complaining of pain in the right side and numbness of the legs. Family history very good. He has been engaged as stevedore and coal-porter all his life, and until three years ago had always enjoyed good health. Is a moderate drinker, never exceeding three pints of beer a day. Three years ago he had severe pain in the chest and slight cough, and is said to have been treated for pleuro-pneumonia. Ever since then he has had pain in the

Digitized by Google

right side, and latterly, he says, the lower part of the abdomen and lower extremities have felt numbed.

Condition on admission.—Looks well, but is of a melancholy disposition, and cannot sleep on account of the pain. He states that he perspires freely, but not on the right side. Digestive system fairly good. Respiratory system: Has a slight cough; physical signs normal, except at right base, where there is dulness, deficient breath sounds, increased vocal fremitus, and pain on movement. Vascular system healthy. Nervous system: Knee jerks equal, and not remarkable; plantar and other superficial reflexes present, and about normal in freedom. The patient does not seem fully cognisant of sensations of heat, cold, and pain. Able to walk, but not well.

The following is a short abstract of the daily notes from the date of the patient's admission until his death:—June 7th: Unable to pass urine; when drawn, found to be alkaline; complains of much pain in the bladder; cannot stand without support.—16th: Passed a motion involuntarily; knee jerks exaggerated; unable to move either leg.—21st: Entirely unconscious of lower extremities.—30th: Legs contracted; commencing gangrene of right heel.—July 19th: Since last note, pain in right side and also pain referred to legs have been the chief symptoms.—22nd: Gland projects at inner end of right clavicle; a bedsore has formed, and is extending rapidly; right leg very sensitive; temperature very variable.—Nov. 1st: In this interval the chief notes are a progressive loss of strength, and complaints of pain in chest, together with a most distressing cough.—29th: Pain of a girdle character and in left side very distressing.—Dec. 14th: Troubled with "fits" and fainting.—Jan. 12th, 1887: Continued to get weaker, and died quietly without any further definite symptoms.

Necropsy.—Body much wasted. On opening the thorax, a large mass was at once apparent, occupying the right upper part of the posterior mediastinum. On further exploration it was found that the new growth had extended into the base of the right lung in a downward direction; upwards, it had infiltrated the glands of the posterior mediastinum, thus producing the bulging above the right clavicle; backwards, it was found to have softened and infiltrated the bodies of two or three of the upper dorsal vertebræ, and to have compressed the spinal cord to such an extent as to have almost obliterated it opposite the fourth dorsal vertebra, with complete softening above and below this point for some little distance. The growth had apparently begun in the neighbourhood of the right bronchus, as here it had softened down into a mass of cheesy, purulent material. The kidney showed acute pyelitis, and the bladder evidence of cystitis. The other organs presented only such changes as might fairly be attributed to the mode of death. The naked-eye appearances of the growth showed that it was an encephaloid, or soft cancer, with much juice and very little fibrous stroma.

Remarks.—The above case is interesting from one or two points of view. Primary cancer of the lung (be it remembered that so careful an observer as Dr. H. Sutton performed the post-mortem examination, and found no other cancerous deposit) is in itself a somewhat rare affection, and it must be rarer still to find examples of a soft cancer in such an important organ as the lung which took three years to kill. I say three years, for unless we take the illness of three years ago to have been the commencement of the growth we have no other possible explanation of its origin. Clinically, the case was one of extreme interest, owing to the difficulty of diagnosis. On admission the signs in the lungs were such as to give one no clue whatever as to the dangerous nature of the case, nor did the nervous phenomena lend us much aid, for, though the paraplegia was somewhat marked, the signs of spinal cord disease were absent or ill-defined. After a week's stay in hospital, however, the signs of acute myelitis rapidly developed, and then, indeed, the case assumed a most serious aspect. But still the diagnosis was anything but absolutely certain, and not till the end of July, when the enlarged gland appeared above the clavicle, could an almost positive conclusion be drawn as to the nature of the case. I can find no mention in ordinary text-books of this particular cause of paraplegia and myelitis—i.e., growth from the lung. I presume the reason is that such growths usually kill before spreading in that direction. The growth appeared not to have infiltrated the cord at all, but merely to have compressed it. I regret to say that a microscopical examination has not been made.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

CASE OF SUPRA-PUBIC LITHOTOMY; HÆMORRHAGE INTO THE BLADDER; RECOVERY; REMARKS.

(Under the care of Mr. J. H. MORGAN.)

NUMEROUS instances of successful operation for the removal of calculus by incision into the bladder above the pubes have been recorded during the last few months. The following case, however, is one in which an unusual complication occurred during treatment, and the account of it, with the remarks of Mr. Morgan, and his explanation of the mode of occurrence of the hæmorrhage, will be read with interest. For the notes of the case we are indebted to Dr. Penrose.

W. G——, a boy, aged six years and a quarter, of healthy aspect, and with no history of previous illness, was brought to the hospital on account of passing blood with his urine, and of pain in micturating. This had existed for two years. Eight months previously he had been circumcised at another hospital. The boy had always lived in London. The mother's family was gouty. The pain and blood followed micturition, and both were worse after exercise. The patient had to rise at night to pass urine. The urine after admission was slightly alkaline, without any albumen. A stone was detected on sounding, which it was decided to remove by the supra-pubic operation.

The patient having been placed under chloroform, a small gum catheter was passed and the bladder emptied of urine; it was then filled with a moderate quantity of boracic lotion, the catheter plugged, and an indiarubber band placed round the penis to avoid leakage by the side of the catheter. A tampon was passed into the rectum and distended with air until the bladder could be seen in outline upon the abdominal surface projecting with moderate prominence. An incision about an inch and a half from just above the symphysis was made in the middle line and the dissection carried down to the fat overlying the bladder, in which one vessel was tied before division. The wall of the bladder being exposed, it was incised, the finger passed in, and the stone immediately detected. This was of moderate size, and was extracted with the aid of forceps. The muscular coat of the bladder was then sewn up by inserting a number of separate fine catgut sutures, the mucous coat being avoided. The wound in the abdominal wall was then united by silk sutures and a small horsehair drain inserted at the lower angle. The stone was composed of uric acid. The catheter was allowed to remain in the bladder.

On the following day the wound, which was dressed antiseptically, looked perfectly quiet. The boy was well, and the temperature normal. Urine, slightly blood-stained, passed through catheter. On the second day the catheter was removed, as it was causing some urethritis, and urine was passed per urethram. The drain from the wound was also removed. On the third day the patient was restless, and complained of pain. The quantity of urine passed was small, and was slightly stained with blood. More was drawn off by catheter. There was a good deal of straining, and, thinking that this might be due to constipation, an enema was administered by the house-surgeon. Pain increased; no sleep. Ordered two minims of tincture of opium. Temperature normal. On the fourth day after the operation, the patient was pale, and the surface cold. The bladder was seen and felt distended up to the umbilicus, hard and tense, but not tender. To relieve this, which was evidently due to the presence of blood, a catheter was passed, and some warm boracic lotion injected. This was repeated several times, the instrument when withdrawn being filled with clotted blood, the fluid dribbling away mixed with blood. The boy slept between three and four hours.

Digitized by Google

During the following night several ounces of blood-stained fluid were passed, and the bladder became softer and less distended. The injections were repeated, with the result of bringing away much more fluid and some clots. The swelling of the bladder was much diminished. On the sixth day the bladder swelling had disappeared, and a good quantity of blood-stained urine was passed naturally. The wound, which up to this time had looked firm and healthy, now showed some oozing, and there was marked tenderness in the right inguinal region. Three stitches were removed, and later in the day urine passed from the aperture. On the seventh day almost all the urine, which was slightly blood-stained came through the wound. The tenderness in the inguinal region was less marked, but there was observed a dark-coloured defined area of skin over the right pelvic region and extending a short way below Poupart's ligament, which was evidently caused by extravasation into the tissues of blood-stained urine. Boy improving. In a few days this staining disappeared, and the amount of urine passing from the wound began to gradually diminish as that flowing from the urethra increased. Healing was complete in the course of another four weeks, and the boy was discharged, but on coming to see Mr. Morgan a short time afterwards he was reported again to have passed some blood with the urine. This, however, has not recurred, and he is now perfectly well.

Remarks.—Any *contretemps* in the progress of a case which follows an operation which may be said to be still on its trial deserves to be recorded, and the above case illustrates two points to which attention has already been drawn. In the first place, it is not desirable, at all events in the case of children, to retain a catheter in the bladder after the suprapubic operation. Although for the first forty-eight hours the urine passed through the catheter, and was therefore not allowed to remain in and thus distend the bladder walls, the urethritis excited by the presence of the catheter was probably the cause of the bladder subsequently becoming distended, and so tearing apart the freshly united edges of the incision and giving rise to the hæmorrhage into the bladder which produced so much tension. It was this also which caused the stitches in the bladder to give way, and had they not been inserted the hæmorrhage might have made its way out by the wound in the abdominal walls and the distress which followed the distension of the bladder avoided. The staining of the tissues about Poupart's ligament on the right side is an interesting feature, and shows that a small amount of extravasation need not lead to any bad results.

NEWCASTLE-ON-TYNE INFIRMARY.

JAW CASES.

(Under the care of Mr. PAGE.)

THE cases were reported by Mr. J. P. Maynard, house-surgeon.

CASE 1. *Epithelioma of the lower jaw.*—Rebecca E——, aged fifty-two, a woman with marked cachexia and much run down, was admitted on May 22nd, 1886, with epithelioma involving the floor of the mouth. Three months previously she had noticed a painful ulcer on the frænum linguæ, which gradually spread rather rapidly over the tongue and floor of the month, with much pain and salivation. Shortly afterwards a swelling appeared beneath the chin.

On admission the floor of the mouth and under surface of the tongue were found to be occupied by an irregular ulceration, with uneven sloughy floor, indurated margins, and binding the tongue down all round as far as the first molar tooth on either side. It involved the lower jaw to a similar extent. All the submaxillary glands were much enlarged, but not adherent to the skin.

As the woman was suffering terrible pain, shooting along both sides of the head, was emaciating rapidly from inability to eat, and was willing to have anything done, Mr. Page, under chloroform, split the chin to the hyoid bone, reflexed the flaps, sawed through the lower jaw on either side by the first molar tooth, and, after passing a silk ligature through the base of the tongue, removed the whole tongue with scissors and dissected the glands out. The linguals were easily secured, and the skin brought together with a fine continuous catgut suture, the ends of the silk ligature, used to hold the stump of the tongue, being brought out through the bottom end of the wound and secured on the chest by strapping; this kept the stump from falling back upon the glottis, and was found useful more than once when that accident threatened.

The woman recovered well from the shock of so severe an operation, and the wound was kept sweet by washing it out frequently with weak Condy. She was fed by enemata the first three days, and by the mouth afterwards. Her recovery was complete; the pain left her, and by degrees the divided ends of the jaw came into apposition, so that she looked like a person with a small retreating chin. She was kept under observation, and on Nov. 1st the following note was made:—"Pain recommenced lately, shooting up left side of face, and swelling appeared below the chin on the left side; mouth healthy.—20th: Ulceration commencing on gum of left half of jaw. Stump of tongue healthy; glands increasing. Some cough.—Dec. 10th: Woman bed-fast; sinking."

CASE 2. *Encephaloid cancer involving lower jaw.*—John H——, aged fifty-six years, married, admitted Nov. 9th; a hard drinker and smoker; no history of syphilis. Twice had toothache ten years ago on the right side, accompanied by swelling. Four months ago he found a small tumour growing from the gum on the right side, with a pedicle. This he removed frequently as it recurred, and then swelling began below the right jaw, without pain, and has increased gradually since. Losing flesh.

On admission the right cheek was found prominent, and the swelling extending into the neck. Surrounding and adhering to the right lower jaw, reaching from the lateral incisor anteriorly as far back as the wisdom tooth, and bulging up on the inner and outer sides of the intermediate carious and loose teeth, was a mass of growth composed of hard, lobulated, elastic material, looking like bunches of large ripe cherries, bright-red in colour, smooth on the surface, and superficially ulcerated in a few places. Occupying the submaxillary space were three large hard glands, adherent to each other, but not to surrounding structures, and passing beneath the sterno-mastoid muscle. The cheek was free, so was the tongue and its movements, though the growth invaded the floor of the mouth.

Mr. Page performed a preliminary laryngotomy, plugged the pharynx with a sponge, and then making an incision along the lower border of the jaw as far as the ear, and in front not quite dividing the lip, he sawed through the jaw by the lateral incisor tooth and turned the jaw upwards and removed it at the joint, afterwards easily shelling out the glands. Hæmorrhage was easily arrested, and the wound stitched with continuous suture of catgut, drainage being allowed for at the angle of the jaw where bagging seemed likely to occur. The wound healed well, some facial paralysis that occurred passing off, as also slight cellulitis of the face that followed. The laryngotomy tube was removed the next day, and the wound healed well. It was intended to keep the tube in and to plug the pharynx, but the sponge excited vomiting and had to be stopped. The growth proved to be encephaloid cancer.

Jan. 20th.—Patient stationary. The recurring attacks of cellulitis (?) have left an "elephantoid" thickening of the cheek.

March 10th.—Growth returning.

CASE 3. *Epithelioma.*—James C——, aged fifty-three, admitted on Oct. 30th, 1886. He suffered from epithelioma of the cheek in August, 1885, which was excised. Ten weeks previously to admission it returned, and has increased.

On admission, the growth involved the whole thickness of the cheek at the angle of the lower jaw and the jaw itself. It had recurred inside the cheek, and was making its way to the skin, which was reddened. The mouth could only be opened half an inch in front, when the inside of the cheek at the angle of the jaw was seen to be ulcerated. No enlarged glands in the neck. On Nov. 17th the skin burst, after which the growth seemed to diminish somewhat in size.

On Nov. 27th, at the patient's urgent request, Mr. Page operated, making a double elliptical incision extending from the angle of the mouth nearly to the lobule of the ear, and including the ulcerated surface. He sawed through the jaw outside the canine tooth and across the ascending ramus, removing the intermediate portion. In order to bring the edges together without the tension there must otherwise have been, a curved incision was made about three-quarters of an inch below, and parallel to the lower one previously made, as in the principle of cheilo-plasty, and then the two incisions sutured, three hare-lip pins being used. The man did well, and, though two of the pins cut partly through, the wound healed up.

Jan. 26th.—There is no return of the disease.

Digitized by Google

Feb. 16th.—Since going out the cheek has gradually becombe œdematous and indurated (as in Case 2).

April 6th.—The growth is recommencing inside the mouth at the old seat. The cheek still remains elephantoid. No pain, and still eats well.

CASE 4. *Sarcoma involving the upper jaw.* — James S——, aged fifty-nine, young for his age and healthy, was admitted on Oct. 1st, 1886. Six months ago he noticed a swelling on the right cheek close to the nostril, the size of a pea. It grew slowly without pain. Never had any discharge from the nose.

On admission the angle between the nose and cheek on either side was occupied by a swelling as large as two walnuts, fixed, elastic, and attached to the superior maxilla on the right side, not adherent to the skin or encroaching on the orbit. On raising the lip it appeared as an elastic red swelling, distorting neither alveolus nor palate. It fills up the right nostril, and its nasal surface is superficially ulcerated, bleeding when touched. There are no enlarged glands in the neck. On puncture a drop of blood escaped.

On Oct. 19th Mr. Page operated, raising the upper lip by cutting through it into the right nostril. Sawing through the upper jaw on either side beyond the lateral incisor tooth, he forcibly removed the inter-maxillary bones with the growth. The growth proved to be a round-celled sarcoma. The case did well, and the deformity was *nil*, his voice having a nasal twang, and occasionally fluids returning through the nostrils while drinking.

On Jan. 31st, 1887, he returned with a recurrence at the seat of removal and in what remained of the right upper jaw. On Feb. 1st the upper jaw was removed, and the antrum was found to be filled with the growth. The man had erysipelas of the face and a mild attack of pneumonia (no preliminary laryngotomy had been performed), and an abscess formed subcutaneously in the left arm. He also had a purulent discharge from both middle ears. These abscesses gradually healed, but his recovery was retarded by a fresh attack of erysipelas lasting some days, and leaving behind it a thickened state of the cheek, as in Cases 2 and 3. On March 26th he was discharged, with evidence of a return of the growth.

CASE 5. *Encephaloid cancer, involving the upper jaw.*—Mary H——, aged fifty-nine, widow, was admitted on Oct. 28th, 1886. Seven months ago she felt pain followed by swelling over the right malar bone. It increased slowly, spreading towards the orbit. No pain in mastication (teeth all lost some years ago), and no discharge from nose and mouth.

When admitted the right face was very prominent; skin reddened and partially adherent. The upper jaw, malar, and half of zygoma were covered by a hard growth, soft in places, which displaced the eyeball upwards, filled the temporal fossa (anterior half), and covered the masseter muscle (upper half), bulging into the mouth between the upper teeth and cheek. No glands enlarged, and the patient had been losing flesh.

On Nov. 6th, on the patient's urgent solicitation, Mr. Page raised the skin by the incision recommended by Mr. C. Heath, and, after dividing the zygoma and nasal process of the upper jaw with bone forceps, sawed through the alveolus from the nostril and avulsed the upper jaw and mass entire, dissecting up the orbital structures from the floor of the orbit. The large chasm bled profusely, but soon stopped with pressure, and the skin flap was brought down with a continuous catgut suture. It healed well, and the woman went home early in December. Her face, which previously had a very anxious and pinched expression, assumed quite a cheerful look. The growth proved to be encephaloid cancer. She came up on January 15th, when there was no sign of any recurrence, though the eyeball appeared in danger of disorganisation. In the beginning of April the growth recommenced at the seat of removal.

CASE 6. *Myxoma involving the upper jaw.*—James M'K——, aged seventy-five, was admitted on Oct. 30th, 1886. Six years ago he noticed a small growth like a raspberry protruding from the socket of one of the left upper molar teeth. He used to remove it with his finger-nail, but it gradually grew too firm and extensive for this. He is a hale and hearty man, looking about fifty-five. There is a growth about the size of a hen's egg attached to the left upper alveolus, red, elastic, and fairly soft. It consists of two parts, the interval between them leading through the tooth socket into the antrum. Under chloroform the growth with a portion of the alveolus was removed. It proved to be a myxoma.

Jan. 20th.—There is a small piece of the growth projecting through into the mouth the size of a pea. He had no pain, and it is uncertain whether it is returning.

March 20th.—The projecting portion is not increasing, and he suffers no inconvenience from it.

CASE 7.—*Sarcoma of the upper jaw.*—J. R——, aged sixty-eight, was admitted on Feb. 24th, 1887. Eighteen years ago he had mucous polypi removed from the nostrils. Last December he felt pain and swelling over the right cheek, which had increased pretty rapidly. Has lost flesh. He is a hearty, strong old man. The interval between the nose and the right cheek is filled up with a swelling, which encroaches upon the floor of the orbit above, passing over, not through, the bone, pushing the eyeball upwards. Below, it bulges in the angle between the cheek and the gum; and inside, it presents in the nose as a red vascular surface. It is elastic and tender; a needle draws off blood only. There are no enlarged glands in the neck. The finger detects a hard lobulated growth projecting through the posterior nares. All organs healthy.

On March 1st Mr. Page removed the entire upper jaw. The growth proved to be soft sarcoma, filling the antrum and the right half of the nose. The patient did well after the operation, and on the 31st went home perfectly well.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Destructive Arthritis of Knee without Suppuration.—Senile Arthritis.—(?) Sarcoma of Knee.—Carcinoma of Spine and Liver.—Diffuse Sarcoma of Spinal Pia Mater.—Interstitial Aneurysm of Inter-auricular Septum.—Tubal Pregnancy.

AN ordinary meeting of this Society was held on Tuesday last, Sir James Paget, Bart., President, in the chair.

Mr. S. G. SHATTOCK read the report of the Morbid Growths Committee on Dr. Edmunds specimen of Horny Papilloma of the Hand, from which it appeared that there was no evidence of genuine malignancy. The necrosis had extended over a period of two years; there were no lymphatic enlargements, and although the operation had been performed twelve months ago, there were no signs of recurrence.

Mr. HUTCHINSON showed a specimen of Dry Arthritis in which there had been an unusual amount of absorption. It came from the limb of a head mistress of a large school, aged forty-five, who had suffered from extreme pain for some time. The tibia was displaced backwards and outwards, but there was no real periosteal thickening. The leg was amputated. The whole of the cartilage was absorbed, and there was much wasting of the femur and tibia without any suppuration, necrosis, or material softening of bone, or, indeed, any fluid effusion. It was not a case of Charcot's disease; there was no evidence of locomotor ataxy; rheumatism was out of the question.

Mr. THOMAS SMITH showed specimens of Acute Senile Arthritis of Tubercular Nature. The first came from a lady aged sixty-seven. She had suffered much from pain in the ankles and knees. Last November she was suddenly seized with severe pain in one knee, which rapidly filled with fluid and the limb became deeply ecchymosed; the body temperature fluctuated between 100° and 103°, and the pulse between 150 and 160. The patient was most unmanageable. In March amputation was performed and recovery followed. The amputation was through the lower third of the thigh. Over the joint surface subject to pressure the cartilage was absorbed; the synovial membranes were thickened and thrown into processes and fimbriæ; there was no sign of ulceration or suppuration. Mr. D'Arcy Power made a microscopical examination, and found miliary tubercle, but not bacilli. The family history showed a marked degree of tubercle in many relatives. A second case occurred in a man aged seventy. The wrist-joint had been affected for two or three months with great swelling; open sinuses had formed, and necrosed bone could be detected through them. The end of the ulna was laid bare and dead. A profuse discharge of pus flowed from the joint. Albuminuria (one-fourth) was present. Amputation through the forearm was followed one month afterwards by death from the effects of chronic heart

Digitized by Google

disease. The joint was much destroyed; the ligaments had given away; the bone was much necrosed. The cases were illustrations of senile struma as recognised by Sir James Paget some years ago, though he gave no evidence as to the microscopical presence of tubercle.—Mr. R. J. GODLEE mentioned the case of an old man with extensive disorganisation of the wrist-joint, in which caseous material was discovered.—Mr. F. S. EVE said that Dr. Lediard had shown a specimen closely resembling Mr. Hutchinson's case.—Mr. MACNAMARA thought there was clear evidence of the existence of degenerative changes due to trophic nerve influence, and yet not a genuine case of Charcot's disease. He had published a case of distinct and definite tubercular disease of the joint, but there were no bacilli.—In reply to Mr. Smith, Mr. HUTCHINSON said that the chronic disease had lasted many years, but the acute destructive disease only three or four months; a microscopical examination had not been made, but there was no evidence of tubercle. He had seen many cases of what he diagnosed as struma in people above the middle age since the publication of Sir James Paget's.

Mr. HUTCHINSON showed a specimen of Tumour of (?) Syphilitic nature. A swelling appeared on the inner side of the left knee-joint of an officer in the Indian army. There was a history of chancre, but no conclusive proof of syphilis. Iodide of potassium failed to effect real improvement. The skin over the tumour was healthy; no nocturnal pain. Mr. Hutchinson thought it most probably was a syphilitic gumma, and iodides of sodium, potassium, and ammonium were given in large doses, and afterwards mercury to full ptyalism, but all without effect. Consultation with Sir James Paget was followed by exploration, and finally amputation of the limb. A soft opaque whitish structure like a sarcoma was found beneath the vastus, and then much grumous fluid was discovered and a bare patch of bone, but there was no ossification of the tumour. The knee-joint was involved. The growth, the size of a fist, was attached above the inner condyle; a central cavity contained glairy fluid and extensive erosion of bone over a surface of about three inches in diameter. Several weeks' treatment with iodide and mercury had previously failed to reduce the swelling. The growth was well defined by fibrous tissue, and to a large extent was made up of this, with collections of round cells at various points. Great numbers of vessels were present, many of which were more or less obliterated by thickening of their walls. Some new formation of cartilage and bone had occurred at the margin. The thickening of the vessel walls by cellular infiltration, together with the erosion of bone, pointed to a specific origin; but the failure of treatment, the absence of any marked gummatous deposit (though some parts were degenerated) were against this hypothesis. Mr. Hutchinson said that two cousins and an uncle had died of cancer. He had never seen a gumma having the naked-eye characters of the tumour in question, nor one which so persistently refused to be cured by specific treatment.—Sir JAMES PAGET said that he had had no serious doubt during life that the growth was a sarcoma, even whilst bearing in mind that mistakes had been made. He thought that tumours expressed themselves as surely in shape and naked-eye characters as they did to the microscope.—Mr. D'ARCY POWER had dissected a similar specimen in a well-marked case of syphilis.

Dr. G. N. PITT showed a specimen of Primary Carcinoma of the Liver, taken from a man aged forty-eight, who had incontinence of urine for two years, and died with paraplegia. There was a large liver weighing 120 ounces, and section of it showed a large white growth of elastic consistence, with forty or fifty secondary growths around. Deposits were found in the kidneys, lungs, and suprarenals. As a unique occurrence, it was found that the eighth dorsal vertebra was entirely replaced by carcinoma. It was probably of scirrhous nature, and primary in the liver, perhaps originating in the bile ducts. Several similar cases have been recorded in the Pathological Transactions. Numerous prostatic calculi were found, and possibly this was related to the enuresis. There was also a mass of growth in Douglas's pouch.—Mr. GODLEE said that Mr. Kesteven had recorded a case of sarcoma, in which one vertebra was completely replaced.—Dr. NORMAN MOORE had never seen a vertebra so completely substituted.—Mr. LAWSON TAIT related a case of papillomatous disease of the peritoneum, from which recovery took place.—Dr. W. S. A. GRIFFITHS said that Mr. Thornton and Mr. Doran had recorded similar cases.

Dr. PASTEUR (on behalf of himself and Dr. COUPLAND) read a paper on two cases of diffuse sarcoma of the spinal pia mater. Case 1 was that of a female aged twenty-two, whose illness began in June, 1885, with headaches and pain in the right shoulder and arm. In September there was severe pain along the spine. On admission to the Middlesex Hospital, on October 7th, 1885, there was impaired memory, paresis of arms and legs, without loss of sensibility, abolition of knee-jerks, and severe pain along the spine and in the occipital region. There was intense double optic neuritis, impairment of vision, and complete paralysis of both external rectus muscles, with simple diplopia. The patient died comatose on the second day after admission. The spinal cord was found ensheathed in its whole extent by a softish grey mass of new growth, most developed on the posterior and lateral aspects. It was situated beneath the arachnoid and was inseparably united to the pia mater. In an upward direction it spread over the pons and medulla, completely investing the sixth pair of cranial nerves, and had extended in the form of isolated nodules to the parietes arachnoid in several places. Downwards the growth had invested the nerves of the cauda equina with thin translucent sheaths, which at intervals expanded into small tumours. The nervous tissues presented normal naked-eye appearances. Microscopically, the growth consisted of closely aggregated small round cells with a small nucleus embedded in a stroma for the most part obscured by the luxuriance of the cell growth. The growth invaded the white matter of the cord at several points, mostly along the lines of the normal trabeculæ. The nerve tissue of the cord showed no pathological changes. Case 2: A girl, aged four years and a half, under the care of Dr. H. C. Bastian. Her symptoms dated from a fall down a flight of steps two months before admission to University College Hospital. The chief symptoms were strabismus, paresis of the legs and arms, and blindness of sudden onset, fourteen days before admission. There was also severe pain in the back and marked weakness of the trunk and muscles. Sensibility was unaffected. Death took place by asphyxia seventeen days after admission, without convulsion. The spinal cord was surrounded by a thickish layer of new growth, especially developed on the posterior aspect. The growth reached upwards to the under surface of the cerebellum, which it invested and infiltrated to the depth of about half an inch. The middle lobe of the cerebellum was almost entirely replaced by new growth. Microscopically, the growth presented appearances almost identical with the previous case, which were rare, and seemed to form a group apart from other kinds of growth in the spinal membranes. Only three cases in which the growth might be presumed to be primary in the spinal pia mater were on record. The notable points in the group of cases were: The extreme diffusion of the new growth, which involved the whole spinal pia mater; the type of tissue, approximating closely to inflammatory tissue, but distinguished by the absence of any tendency to become organised or to undergo retrogressive changes; the limitation of the growth to the spinal pia mater; the age of the patients—four and a half, sixteen, and twenty-two years respectively; the brief duration of the symptoms—about three months in each case; the absence or impairment of knee-jerk and other reflexes in connexion with the involvement of nerve roots; the absence of convulsions; the presence of constipation; the presence of fundus changes in the two cases in which the disease reached the brain. The cause of death in all the cases was interference with respiration.—Dr. J. A. ORMEROD said that a somewhat similar case had been recorded by Dr. Long Fox in the *Bristol Medico-Chirurgical Journal*.—Dr. HADDEN referred to some cases of a similar kind published as chronic meningitis in the last volume of the Pathological Transactions.

Dr. MAGUIRE showed a specimen of Interstitial Aneurysm of the Inter-auricular Septum. The aortic valve was stenosed, and the cusps much thickened by inflammatory growth and covered with fibrin, in which no micrococci could be found. Anterior to and below the foramen ovale a cyst filled with partly disorganised clot was found, which turned out to be really an aneurysm. There was some ulceration below the aortic valve, which communicated by a narrow fissure with the cavity of the aneurysm. The precise mode of origin was doubtful. As affecting a part of the body rarely the seat of morbid changes, the specimen was of much interest.

Mr. LAWSON TAIT communicated an additional note on the Pathology of Extra-uterine Pregnancy. The theory of extra-uterine pregnancy which he advanced in 1873 has

Digitized by Google

met with only one objection. His theory, based on the belief that the rupture of the tube was caused by the placenta, it was urged, could not be accepted because the placenta was not differentiated until after the third month, whereas these ruptures generally occurred between the tenth and twelfth weeks. Carpenter said that "the formation of the placenta commences in the latter part of the second month, and during the third the organ acquires its proper character." In fact, according to Goodsir, the changes upon which depend, in Mr. Tait's belief, the ultimate rupture of the tube begins before the end of the first month. He meant the immersion of the fœtal tips in the maternal tissue and the formation of new vessels and the great increment in size of those in previous existence. The ultimate localisation of this immersion for the subsequent differentiation of the placenta is evident long before the completion of the eighth week. All the facts are completely proved by two preparations of the Pathological Series of the College of Surgeons Museum (4691 and 4691*a*). In a post-mortem examination made in 1874, in which he succeeded in perfectly injecting the uterus, ovaries, and tubes, the enlarged maternal vessels at the edge of the placental site were clearly the reason of rupture, and the source of the fatal hæmorrhage. The difference in the uterus and the Fallopian tube in the matter of a contained fertilised ovum is that the uterus has the power of indefinitely increasing the thickness of its walls, whereas the tube has no such power, or has it to a very limited extent. The site of the placenta as a seat of active nutrition, wherever it may be, becomes extremely vascular, as is proved by preparations now exhibited. If the tissue in which this change is effected is also infiltrated by soft villi, naturally of a kind easily torn, and if it does not increase proportionately in strength, it must offer a feeble resistance to the pressure of the rapid growth of the ovum. There are many other preparations illustrating and confirming these points. Dr. Heywood Smith's specimen was removed from the living abdomen as a pediculated tumour, and the conditions were such that it seemed that at last a case had been found that unhinged completely Mr. Tait's theory of extra-uterine pregnancy. This preparation was submitted to a committee for report, which read as follows: "The specimen consists of a fœtus and placenta corresponding to the fifth month of gestation. Also the Fallopian tubes, with the ovaries. The sac containing the fœtus and placenta is made up of involuntary muscle fibre, and resembles in structure the Fallopian tube, portions of which from the same case were cut and prepared for the microscope, and compared with the sac wall. Sections were also taken from an undoubted case of tubal pregnancy which had advanced to the fourth month of gestation. The sections from the two cases were identical. The outer wall of the sac presents pieces of omentum, showing that fairly strong adhesions had arisen between the dilated tubes and the omentum. The Fallopian tube corresponding to the sac, &c., was scarcely represented except by fimbriæ. The corresponding ovary contains a large corpus luteum. There is no evidence of rupture of the tube, and there can be no doubt that the specimen is one of tubal gestation." What, then, is wanted now for the modification or destruction of the author's theory is a preparation of extra-uterine pregnancy which is inconsistent with a tubal origin, or a case of tubal pregnancy which has not ruptured either into the peritoneum or into the broad ligament at or before the twelfth week of ovum life. Dr. Berry Hart dissected a specimen of extra-uterine pregnancy, and subjected it to the process of freezing and longitudinal slicing. It is a case of tubal pregnancy ruptured into the broad ligament, and developed there until at least the eighth month—perhaps longer. Unfortunately, nothing is known of the history, but the fortunate sections cut by Dr. Hart absolutely prove beyond all criticism what he (Mr. Tait) had convinced himself of by the facts observed by him in operating upon these cases—that they are originally tubal, and that they develop in the broad ligament, pushing its layers and those of the peritoneum upwards and backwards and towards the centre. In operating on these cases, sometimes he opened the peritoneum and sometimes not. The reason is made plain by Dr. Berry Hart's sections, where the uterus is central. The growth of the pregnancy has stripped the tubal and peritoneal layers and carried them upwards, but a moment's consideration will make one conclude that the peritoneum could be stripped off the posterior wall by the uterus only; it could not be shifted from the anterior wall of the uterus and bladder, though these were pulled well up. But immediately on each side of the uterus the peritoneum has been shifted off the transversalis fascia as far up as the umbilicus, leaving a long conical tube of the peritoneal cavity reaching down over the median line of the fœtal mass as far as, and corresponding in diameter to, the uterus. In some cases the uterus was central, but in the majority it was not. Dr. Berry's Hart's drawings showed why it was that sometimes the peritoneum was opened and sometimes not. When this peritoneal tube was central, it was opened; when it was not, Mr. Tait missed it: so that these operations were sometimes to be ranked as abdominal sections and sometimes not. He submitted also sections of the tube in early tubal pregnancy, showing the immersion of the fœtal villiin to the tissue of the Fallopian tube, and the consequent enlargement of the tubal vessels.

The following card specimens were exhibited:—Mr. E. H. Fenwick: Urinary Tuberculosis with Multiple Calculi. Dr. Barlow: Renal Sarcoma in a Child. Mr. Page for Mr. Raven: Sarcoma of Dorsal Vertebræ. Mr. Shattock: Tubercular Arthritis. Mr. R. J. Godlee: Bones of Limbs, Skulls, and Sternum, infiltrated with Sarcoma.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

The Presence of Mould Fungi in connexion with Diphtheria.

AT the meeting on April 13th (Surgeon-General John Murray, M.D., Vice-President, in the chair), Dr. MICHAEL W. TAYLOR read a paper on the Presence of Mould Fungi in connexion with Diphtheria. He gave the whole evidence he possessed, which he had collected from many years' experience of outbreaks of diphtheria, in support of views he had formerly expressed in the *British Medical Journal*, July, 1881, on the fungoid origin of diphtheria. He had ventured on a deduction from these observations, which he laid down as a proposition to be worked out—viz., that some common mould fungi growing under certain conditions may originate or transmit diphtheria. The first set of cases comprised three children in one house, who took diphtheria within a few days of each other; no exposure to infection; absence of all evil extrinsic conditions, except the state of the bedroom they slept in. The walls, in consequence of leakage, had become sodden with wet on July 12th. On July 22nd a fungus appeared on wet plaster. On August 1st appeared the first case of diphtheria, rapidly followed by two others, in the children who occupied the room. At this time the surface of the wall was covered with aspergillus mould, besides which there was a surprising development of a pileate fungus, a coprinus, growing on the wet plaster. Second case: Child with diphtheritic exudation on fauces, extending to larynx, and death in three days. Leakage through walls of house some time previously, from storms of wind and rain; great development of penicillium moulds in the apartment; a large quantity of recent skins of cats, covered with mould, stored in an adjoining chamber. Third case: A young man, who had diphtheria severely four days after having been engaged for a whole day in cleaning out a loft in which a number of pigeons were kept, which was full of mould growing on the exuviæ and débris and rotten wood-work. Fourth series: A rapid series of cases in four children in the same family, in which the only insanitary condition known to have existed was the presence of a quantity of fleeces of sheep's wool, which had been stored for two years within the house in an adjoining room. Fifth series: Three outbreaks of diphtheria in a farmhouse, one case in 1879, four cases in 1880, two cases in 1881. Here also wool had been stored within the house, until there had been an accumulation of six years' clippings, and it was kept in a room which had been successively used by these children as a sleeping apartment. The author regarded the evidence in these cases as pointing strongly to the storage of wool, and to the mould spores and dust proceeding from it, as being the exciting causes of three successive outbreaks of diphtheria. After citing the observed phenomena, the author proceeded to work out the probabilities of common moulds being connected in some way as agents in originating the diphtheritic growths. The presence of fungoid organisms, found in the exudations of diphtheria, were of pathogenic import. It was shown by researches of Oertel, Nasiloff, Ebert, and others, that diphtheria is a true mycosis, and that we are warranted in believing that it depends on the implantation of fungoid material endued with virulent power. Evidence was sought from analogy of what obtained

Digitized by Google

in other fungoid parasitic affections infecting man and animals; it was shown that many of these fungal productions were but conversions of elementary states of penicillium and oïdium. As maintained by Zopf, there may be a pleomorphism amid pathogenic micro-organisms, and that there are stages of intermediate forms resulting from the nature of the nutrient media. Common moulds are capable of artificial growth in the bodies of animals; the spores of aspergillus glaucus have been made to germinate in the eyes of rabbits; and there is a ready-made experiment in the Madura foot disease, which arises from inoculation with the spores of a mucor, growing in the hot season in India. The innocent bacterium and aspergillus may by special cultivation become pathogenic, according to Grawitz and Fepinger; the experiments in this direction by Nägele and Büchner were referred to; and also Lichtein's experimental inquiry on pathogenous mould fungi. So the author claimed that this speculation from bedside experience was sustained by the experiments of the laboratory. He regarded the primary elements of zymotic disease as dependent not on individual forms of germs, but an affair of soil; and inferred that common moulds, both by spores and mycelium, might originate diphtheria by growing on noxious media.—In the discussion which followed Surgeon-General Murray, Sir William Smart, Drs. Thorne and Burns, and Messrs. Shirley Murphy and Paget took part.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on April 1st.

Mr. JOHN POLAND showed a patient after amputation at the knee-joint by Bryant's method, leaving the inter-articular fibro-cartilages and their fascial surroundings intact. The stump was an excellent example of the result of this form of amputation.

Mr. JOHN POLAND then read a paper on the Diagnosis of Traumatic Separation of the Epiphyses. The chief points in the diagnosis of these injuries were fully discussed. Special importance was attached to the particular period of age in which it occurred in particular bones. At this time the separation was found to be of a simple character and complete—that is, completely through the epiphysiary line of cartilage. Above and below this age the detachment was frequently incomplete or partial, and often very complicated, defying the most skilled surgeon to give an accurate account of the precise anatomical condition of the lesion. Separation of the epiphyses without displacement was described as a most important practical point to be constantly borne in mind, otherwise a number of these injuries would be overlooked. Stripping up of the periosteum, and its subsequent inflammation, were found to take place in this, as well as in the case of a complete separation, but to a much less extent. The question of prognosis, especially as regards the partial separation, was mentioned, as well as the various dangers likely to be met with. Acute joint disease, as in the hip, was often the result of a separated epiphysis. The paper was illustrated by cases that had been under the author's treatment and by specimens from Guy's Hospital museum.

Reviews and Notices of Books.

The Treatment of Spina Bifida by a New Method. By JAMES MORTON, M.D., L.R.C.S. Ed., Professor of Materia Medica in Anderson's College, lately Surgeon and Clinical Lecturer on Surgery in the Glasgow Royal Infirmary, &c. With a paper on the Pathology of Spina Bifida by Dr. JOHN CLELAND, Professor of Anatomy in the University of Glasgow. London: J. and A. Churchill. 1887.

DR. MORTON has considerably enlarged his book in this edition, and by the accumulated experience of the results of his treatment of spina bifida is enabled now to speak of it more confidently than before. The interest that would otherwise have attached to the republication of this *brochure* has been greatly lessened by the issue of the report of the Committee of the Clinical Society of London on the whole subject of the treatment of spina bifida. Not only was this committee a strong one, but its investigations into the clinical side of the subject and into the pathology of the deformity, so far as they went, were so extensive and careful, and their conclusions so well considered, that it would seem as if but little were left in this field for any other investigators just at present; and Dr. Morton relies to a very large extent indeed upon the committee's report for the general facts in this essay. Of course he adopts the committee's view that his treatment is the best at present known, and he supplements it in three particulars—1st, that the percentage of recoveries under it is larger than that found by the committee; 2nd, that he would not exclude from its application even the cases considered desperate; and 3rd, that he would employ it at an earlier date than the committee recommend. A large part of the volume consists of the detailed records of cases under the care of Dr. Morton and other surgeons, and we wish a good table of all the cases known to the author had been appended, for in its present form the book is not well suited for reference. Considerable interest attaches to the short chapter on the Pathology of Spina Bifida, contributed by Professor Cleland. Premising that "it cannot be said that the committee has placed the pathology of spina bifida in a satisfactory position," he points out that "open spina bifida without tumour" must be studied together with the commoner variety of the deformity. Dr. Cleland argues that the essence of spina bifida is a dropsical effusion into the central canal of the spinal cord. The non-tumescent form is not only often associated with but is allied to anencephalus, in that each is due to rupture of a dropsical sac. Tumescent spina bifida he groups into metaneural and perineural varieties—in the former the effusion being behind, and in the latter surrounding, the nerve roots. The metaneural effusion Dr. Cleland believes to be syringocele, or dropsy of the central canal of the cord, or an effusion secondary to this—basing this contention on the frequency of syringocele (three out of five specimens in William Hunter's Museum), and on the fact that in all cases the cord extends down to the sac and does not undergo the usual developmental retraction. Similarly, perineural effusion is based on a burst syringocele in some instances, and in others is associated with an unburst syringocele. The conclusion drawn is that "spina bifida, in all its varieties, implicates in the first instance the interior of the cord."

Rest and Pain. By the late JOHN HILTON, F.R.S., F.R.C.S. Edited by H. A. JACOBSON, B.A., M.B. Oxon., F.R.C.S., Assistant-Surgeon to Guy's Hospital. Fourth Edition. London: George Bell and Sons. Pp. 514. 1887.

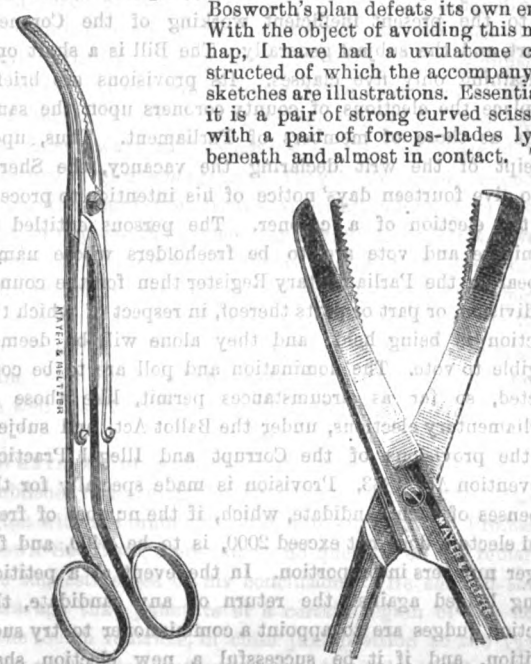
THE profession will welcome a new edition of this classical work, which has lost none of the popularity and appreciation bestowed upon it when it first appeared in print under the personal supervision of its learned author. In his editorial preface Mr. Jacobson states that he has made very few alterations in the present edition, on the grounds that since "the author's death renders his name less and less familiar to the generations that are rising, it has seemed more right to leave his book without further changes." We entirely subscribe to this explanation. Mr. Hilton's work is *facile princeps* of its kind in our own or any other language. Its pages teem with facts—dry perhaps in themselves—but rendered palatable, instructive, and interesting by reason of the clinical and physiological interpretations that have embellished them. No one can rise from a perusal of its pages without admiring the ingenuity of the reasoner and the practised skill of the surgeon who, alas! is now lost to science and humanity. Some of the arguments adduced in support of preconceived opinions may seem fanciful and far-fetched when scrutinised by strict logical laws, but, for all that, none can doubt the sincerity and enthusiasm of the writer who gave an affirmative answer to the interrogation contained in Divine writ, "Can these dry bones live?"

Digitized by Google

It may be safely said that the late Mr. Hilton touched no subject which he did not adorn; and his pages now under review will stand as his lasting monument. In Mr. Jacobson the author of the work found a worthy disciple, and one well fitted to take the responsibility of editorship. Wherever Mr. Jacobson has altered the original text, or amplified it, it has been done with the purpose of rendering it more accurate and complete, and no one can deny that his task has been successfully accomplished. The additions to the work are chiefly in the form of foot-notes, so that the primary plan and substance remain much as they were in previous editions—a procedure far preferable to that which more commonly obtains in excising and substituting, until by mutilation recognition of the author's handiwork is all but impossible.

Practical Pathology: an Introduction to the Practical Study of Morbid Anatomy and Histology. By JOHN LINDSAY STEVEN, M.D. Glasgow: Jas. Maclehose and Sons. 1887.

THE thoroughness with which pathology is pursued in the great schools beyond the Border is reflected in the manuals that have been issued of late from two of the University towns. Dr. Steven's book is the less ambitious of the two, but not less useful, and we can congratulate him upon the manner and style of its production. In the present day our pathological departments ought to be so equipped and conducted that no post-mortem examination should be considered complete unless it included records of histological as well as of gross anatomical appearances. This will not be possible until a more generous recognition is given by the responsible authorities to the pursuit of this subject, for it would necessitate a greatly increased staff and outlay. Yet it has always seemed to us that every effort should be made to perfect our means of pathological investigation and instruction. Much has been done of late years to facilitate such studies, but their value will not become appreciated until examining boards take more cognisance of real practical knowledge. To the earnest student bent on seeing for himself the facts of which he reads, such a manual as that of Dr. Steven will be invaluable. It is not too diffuse or too technical; and although it lacks illustrations, they are not absolutely needed, for the best illustration is that afforded by the specimen itself.



New Inventions.

A NEW SEWAGE PRECIPITANT.

MR. KINGZETT, the well-known inventor, or we might perhaps more correctly say the discoverer of "Sanitas," has patented a very simple agent for the precipitation and utilisation of sewege. This agent is powdered coke. The great value of gas coke as a filtering agent for water was demonstrated, we believe, for the first time by Dr. Percy Frankland, but Mr. Kingzett is doubtless original in suggesting its use in the clarification of sewage. The powdered coke is first mixed with a certain proportion of clay, to increase the density of the precipitant, and is then well mixed with the sewage. It is said that the deposit can most readily be pressed, and that the cake has a certain, although not great, manurial value. What is even more important, the cake can be air-dried and used without nuisance as fuel, or may be carbonised by heat and used again as a precipitant. The suggestion is an interesting one, for every gasworks turns out a quantity of breeze or coke dust, which is sold at a very low rate, and is often hard to sell at all. It certainly seems possible that this breeze, more finely powdered, may prove an economical sewage precipitant. We can express no decided opinion as to its sanitary value, but it promises well, and we shall be glad to hear that it has been properly tried. Mr. Kingzett, in his circular, does not tell us how much of his material would be required. Indeed, he does not seem to have gone beyond laboratory experiments.

A NEW UVULATOME.

UVULATOMY gives very various results in the subsequent degree of discomfort during cicatrisation, according to the method and skill of the operator. It was Bosworth of New York who first pointed out the advisability of cutting in a direction upwards and backwards, so that during deglutition the bolus of food should not come in contact with the raw surface. In order to effect this, he directs that the uvula be seized with forceps, drawn forwards and cut in the direction indicated, with ordinary scissors. That the subsequent discomfort when this is satisfactorily accomplished is infinitely less than when the wound is horizontal I can assert from comparison of the two methods. But the means he advocates are neither simple nor efficient. The chief objection is the drawing forwards of the uvula with forceps; for the loose union subsisting between the mucous membrane and the muscular structures enables the former to be drawn off the latter, and the operation inevitably leaves the stump denuded of its coverings. And thus Bosworth's plan defeats its own ends. With the object of avoiding this mishap, I have had a uvulatome constructed of which the accompanying sketches are illustrations. Essentially it is a pair of strong curved scissors, with a pair of forceps-blades lying beneath and almost in contact. The

latter, while the scissors are still wide open, grasp the uvula. The projecting arm at the end of one blade, which the artist should have represented half as long again, prevents the uvula from slipping back during cutting. With the mouth wide open and the tongue depressed, the patient is instructed to breathe in and out gently through his nose, whereby the velum is relaxed and the uvula brought into a vertical position. This is the more easily effected, since an elongated uvula is generally accompanied by a semi-paretic condition of the soft palate, both being probably dependent upon a chronic congestion of muscular tissue as well as mucous membrane. The instrument is then opened wide, and that portion of the uvula which it is desirable to remove is carefully included in the forceps-blades and rapidly cut through. If the operation has been efficiently performed, we should be unable to see the cut surface. It is scarcely necessary to add that no more than the redundant mucous membrane should be removed.

The instrument has been made for me by Messrs. Mayer and Meltzer, who have shown great ingenuity in securing simultaneous action in the two parts of the mechanism.

Upper Wimpole-street. GRENVILLE MACDONALD, M.D. Lond.

OPAQUE GLASS DRAINAGE-TUBES.

MESSRS. WOOD of Manchester have made for Mr. W. R. Dambrill-Davies some drainage-tubes of opaque white glass. The advantages of the glass tube are its rigidity and its cleanliness; its disadvantages are its brittleness and the difficulty of exact adjustment. The special merit of the opaque tubes is that their position in a wound is at once apparent. They are made of three sizes as to calibre, and of various lengths.

THE LANCET.

LONDON: SATURDAY, MAY 7, 1887.

A BILL to Amend the Law relating to the Election of Coroners has been brought in the House of Commons by Mr. WOOTTON ISAACSON. It also bears the names of Mr. E. T. GOURLEY, Mr. W. AMBROSE, Q.C., and Colonel HUGHES. The opportunity is a favourable one for considering it, together with the report (a condensed notice of which appeared in THE LANCET for March 12th last) issued by the Manchester Medico-Ethical Association as to the present inefficient working of the Coroner's Court, and the subject generally. The Bill is a short one, containing only five clauses. Its provisions are briefly to place the elections of county coroners upon the same basis as those of members of Parliament. Thus, upon receipt of the writ declaring the vacancy, the Sheriff is to give fourteen days' notice of his intention to proceed to the election of a coroner. The persons entitled to nominate and vote are to be freeholders whose names appear on the Parliamentary Register then for the county or division, or part or parts thereof, in respect of which the election is being held; and they alone will be deemed eligible to vote. The nomination and poll are to be conducted, so far as circumstances permit, like those at Parliamentary elections, under the Ballot Act, and subject to the provisions of the Corrupt and Illegal Practices Prevention Act, 1883. Provision is made specially for the expenses of each candidate, which, if the number of freehold electors does not exceed 2000, is to be £400, and for larger numbers in proportion. In the event of a petition being lodged against the return of any candidate, the election judges are to appoint a commissioner to try such petition, and if it be successful a new election shall take place. The Bill is well designed to remedy most of the evils of the present system, and deserves every support.

It is to be regretted that the Manchester Medico-Ethical Association made no allusion to medical coroners, but merely expressed an opinion "that the qualification and position of a coroner should be those of a stipendiary judge, who should devote the whole of his time to the duties of his office, and that his salary should in no case be dependent upon the number of inquests." Even if there had been an overwhelming majority in favour of legal coroners, it would have been just to have paid some tribute to the many medical men who have filled the offices both of borough and county coroners with credit to themselves and to the best interests of the public. This would have been more apparent to the latter than it is if medical coroners had more fair play, and had been appointed in anything like a just proportion to their legal brethren. But out of 286 coroners in the Medical Directory whose qualifications are stated, only 49 are medical, while 237 are legal coroners. And the experience of Lancashire is negative, medical coroners being altogether unknown there, which fact may be a possible explanation of their being so ignored in a report issuing from Manchester. There is, however, a still more weighty argument in favour of medical coroners at the present day than there has hitherto been. Judges have strongly condemned the committal of prisoners on the coroner's warrant alone, urging that there should be for every criminal charge an inquiry before the magistrates and a bill of indictment to lay before the grand jury. This would imply what has always been contended for in THE LANCET, that the duty of the coroner is solely to inquire into the cause of death, and this is obviously more the function of a medical than a legal coroner. The more legal duties and egal questions are eliminated from the office the better. Such verdicts as "Found dead," "Found drowned," "Died by the visitation of GOD," are more suggestive of antiquated formalities than modern records of the cause of death, and they are verdicts generally recorded at "legal" coroners' inquests.

The Manchester report, which is of a somewhat sweeping character so far as its reforms go, further suggests "that the coroner should have no discretion but to hold an inquest in every case of death, sudden or otherwise, in which the cause of death cannot be certified by a legally qualified medical man." This is scarcely practical, even with the qualifying addendum: "It is not implied that the coroner should be necessarily debarred from holding an inquiry, provided there exists reasonable grounds for suspicion, because a death has been certified by a legally qualified practitioner." It is undoubtedly true that the discretionary powers of coroners are at present far too great, and that they have often been used very unwisely, especially by legal coroners. But to give coroners no discretion whatever would be only adding to the useless and formal inquests which are already far too numerous. Many cases must be referred to the coroner in which the want of a medical certificate is more or less accidental, and yet where an inquest is wholly unnecessary; it is these preliminary inquiries, indeed, which constitute a very important part of a coroner's duties. This discretion to be used wisely, and the conduct of these preliminary inquiries require a medical training, and can only be properly left to a medical coroner. The report proposes to continue the coroner's jury, but that it should be a properly constituted one, of an improved social status; it deprecates the present custom of "viewing the body" as objectionable and unnecessary; it advocates the providing of mortuaries with proper appliances in every coroner's district. It also suggests that registrars of deaths "should have no option but to report to the coroner every case of death brought for registration the cause of which has not been duly certified by a legally qualified medical man"; and proposes an amendment to the present form of certificate giving "the period of attendance of the medical man." It also raises again the importance of registering still-births, urging "that the registration should be made, as in other cases, only under a medical certificate, which should state that the certifier had attended the mother during her confinement or had inspected the body of the child within a few hours after birth. Failing this that a coroner's inquiry should be necessary." To meet objections on the ground of expense to the poor, it is suggested that the payment of the medical inspection might be charged upon the local authorities. All these suggestions are very good, and though

Digitized by Google

somewhat in advance of the time, they are practicable and must sooner or later be adopted. The remaining portion of the report we must reserve for consideration until next week.

SIR WILLIAM MAC CORMAC is certainly to be congratulated upon his choice of the subject of his Oration at the Medical Society on Monday last. "Abdominal Surgery" is fast losing the charm of novelty, and the marvellous results attained in this branch of the surgeon's art are familiar to all, and cease to excite the wonder with which they were first received. Sir WILLIAM MAC CORMAC wisely devoted himself to a consideration of one branch of this great subject, which has been the last to receive its meed of notice at the hands of surgeons, and has indeed only been opened up by the large experience now gained in the removal of abdominal tumours, and of the many contingencies attending it. The treatment of Injuries of the Intestine was the theme of the Oration, and it is one well worthy of the attention of English surgeons. Our American brethren at present bear the palm in this region of operative surgery, and it is to BULL, DENNIS, and SENN, among many others, that we are indebted for the best recent papers on this subject, and the best cases illustrating the line of practice they advocate.

Intra-peritoneal wounds of the intestine are certain to lead to fæcal extravasation, which is nearly always fatal from intense septic peritonitis. Experience has shown that wounds of the intestine can be safely sutured, and that prompt and thorough cleansing of the peritoneum may avert septic peritonitis. We are able now to follow out the practice inculcated by BENJAMIN BELL, and Sir WILLIAM MAC CORMAC'S Oration was but the enforcement and exemplification of that great surgeon's teaching. Intestinal injuries may be easily classed into stab wounds, gunshot wounds, and ruptures. The first great difficulty that besets the surgeon in their management is that of diagnosis. We doubt if there is anyone of large experience in surgery who cannot from his own practice cite striking examples of the misleading appearance of harmlessness these lesions often present. As these lesions are so extremely fatal, the very difficulty of diagnosis imposes the duty upon the surgeon of clearing up the doubt and of determining with certainty whether or not they are present. This is the first point that needs to be made plain. To wait until the diagnosis is certain is to miss the golden opportunity for treatment, and to allow the onset of septic peritonitis to rob the patient of nearly every chance of life. Hence, when the doubt exists, it should be cleared up by a careful aseptic exploration, first of the wound in the parietes, to see whether it is perforating or not, and next of the abdominal viscera, to ascertain whether and where they are injured. This may be a difficult task, and, if undertaken at all, must be done systematically and with the utmost precision. But it is also the step at which some, perhaps many, surgeons will pause. While quite ready to admit that when a wounded intestine is known to exist it may be best to suture the wound, cleanse the peritoneum, and close its cavity, they will hesitate before they adopt the bolder step of seeking out the injury when the symptoms do not indubitably point to it. To some extent their scruples will be just. While such an exploration may be urgently needed when the intestine is wounded, it should not be practised when only a suspicion of such an injury exists, and the surgeon must weigh most carefully all the circumstances of the case before adopting so grave a procedure as the systematic inspection of all the abdominal viscera. Such a case is just the one to test the mettle of a surgeon, and the practice advocated, while good in the hands of the wise, may be fraught with evil in the hands of the careless.

An intestinal wound having been discovered, the proper line of treatment undoubtedly is to close it with the utmost care by the Lembert suture, and, having cleansed the peritoneum, to close the external wound. Such a line of practice is not good in theory only. Already its results in practice are encouraging, and likely to become more so when surgeons are more familiar with such proceedings. Of eighteen stab wounds so treated, success has been obtained in ten. Among thirty cases of penetrating gunshot wounds of the abdominal cavity, seven have been saved by this means. There is, however, one feature in these cases that must always militate against success. They are of the nature of surgical emergencies. They do not permit of special preparation, and the circumstances attending them often tend to depress the patients and unfit them for a severe operation. But in spite of all this, and of all the grave difficulties attending the subject both in diagnosis and treatment, it cannot be doubted that the facts contained in Sir WM. MAC CORMAC'S address are evidence of another advance gained by surgery, and the arguments deduced from the facts are well deserving the careful consideration of surgeons.

WHATEVER of scientific truth may eventually become established concerning the reflex relationship of the cervical region with the brain and bulb, now set forth by Professor BROWN-SÉQUARD, there can be no question of the remarkable suggestiveness of his conclusions. He showed some years ago that puncture of a certain region of the floor of the fourth ventricle, in close juxtaposition to the vaso-motor and cardiac centres, but not identical with them, has the effect of reducing to the lowest possible ebb the nutritional changes of the organism, so that the blood in the veins runs red as that in the arteries; for the protoplasmic tissues neither absorb oxygen nor disengage carbonic acid, being, in fact, in a state of suspended animation. But this is not the only cessation of activity that may be brought about as the effect of puncture of the floor of the fourth ventricle. The activity of the cerebral cortex may also be suspended by a similar operation; and actual death may also occur. To sum up in a few words the latest conclusions of the distinguished experimental pathologist, we may state that the skin of the neck covering the larynx has, like stimulation of the larynx, though in a less degree, the power of inhibiting the sensibility of the body, and, further, that mechanical irritation of the larynx, trachea, and perhaps of their superjacent skin, possesses the power of causing death, in the same way as though the bulb or medulla oblongata were irritated. These are extremely important conclusions, and it will be well to examine the evidence on which they are founded. The following is the gist of Professor BROWN-SÉQUARD'S communication to the Académie des Sciences.

It has often excited surprise that suicide by cutting the

Digitized by Google

throat should be carried out with such determination, and apparently at the cost of enormous suffering, indicating an almost superhuman courage. The surprise, however, would be considerably lessened if it were true, as is now asserted, that mechanical irritation of the skin covering the larynx, as well as of the larynx itself, causes total analgesia, as seems possible from the remarkable experiments Professor BROWN-SÉQUARD made some four years ago. After having made a longitudinal incision through the skin of the middle line, or transversely from one side to the other, in the anterior cervical region, the Professor observed in a great number of experiments, especially in dogs and monkeys, that he could lay bare, cut, bruise, galvanise, and even burn the various structures in the anterior two-thirds of the neck without causing any great pain, and sometimes without appearing to cause any pain whatever. Such facts—verified hundreds of times during the last five or six years—prove that these structures have the inhibitory property of causing general analgesia, though in a varying degree, according to the precise structure stimulated—viz.: (1) The maximum effect is produced by stimulation of the mucous membrane of the larynx—i.e., of the parts supplied by the terminal ramifications of the superior laryngeal nerves. (2) In a less degree irritation of the trunks of these nerves, and in a still less degree of the trunks of the vagi above the point of emission of the superior laryngeal nerves, causes the same result to appear. (3) A transient analgesia of variable completeness may be caused by ligature of the trachea. (4) The minimum effect is caused by the irritation of the skin covering the throat, and especially of that over the larynx proper. Although incision of the various structures is the most effective in bringing about the analgesic effects, it is not the only irritation that possesses this property. The trigeminal and other sensory cranial or spinal nerves in their trunks or ramifications do not appear to be endowed with the special power that the vagus nerves and the nerves of the cervical region possess. Surgeons performing tracheotomy during the asphyxia of a patient may be incorrect in supposing that the asphyxia confers immunity from pain, for doubtless the analgesia is partly owing to the very incision of the skin of the front of the neck. Other experiments on animals seem to show that stimulation of the anterior cervical region, especially the larynx, but also the trachea, and probably the superjacent skin, has the power of stopping the heart, inhibiting the respiration, and suspending consciousness. When Professor BROWN-SÉQUARD has killed dogs by cutting their throats, he has found that nearly always, if not always, death occurred without convulsions, without agony, in a state of perfect syncope, permitting the protoplasmic tissues of the body to preserve for a long time their special properties: the blood running red from the arteries to the veins, and thus presenting an absolute contrast to death due to asphysia, where the arteries are filled with black blood.

AN article descriptive of the morbid conditions in twenty-five cases of tubal disease operated upon by Prof MARTIN, is contributed to the current issue of VIRCHOW'S *Archiv* by Dr. E. G. ORTHMANN. It should be read with interest at this time, when so much is being said regarding the clinical aspect of the chronic inflammatory changes to which the uterine appendages are prone. Dr. ORTHMANN describes in detail the histological characters of his specimens, and in the first place draws attention to the normal structure of the Fallopian tube. The wall of the tube is composed of three layers—the mucous membrane, which, covered with ciliated epithelium, is disposed in longitudinal folds, which towards the free extremity become branched and divided, ultimately forming the so-called fimbriæ; the muscular layer, greatly developed in the uterine segment of the tube, and diminishing in thickness towards the abdominal extremity; and the outermost connective-tissue layer. The morbid conditions described fall under five heads, and each case is related in full. Of *catarrhal salpingitis* there were nine cases, six being unilateral. The disease is not limited to the mucous membrane, nor does the ciliated epithelium at first suffer, the change commencing with thickening of the mucous membrane, and consequent irregular swelling of its folds. The swollen folds coming into contact, the cells are compressed, degenerate, and disappear. More or less cystic cavities form between the thickened folds of mucous membrane; and bloodvessels in the infiltrated submucosa may rupture, giving rise to hæmorrhage into the cavity of the diseased tube. Such hæmatosalpinx may result from a closure of the fimbriæ. The muscular and fibrous coats of the wall of the tube may also be thickened, often with atrophy of the muscular fibres themselves. In five cases the "ostium abdominale" was occluded, partly by hypertrophy of the mucous folds, partly by adhesive peritonitis. The following varieties of catarrhal salpingitis are enumerated, the term "catarrhal" being obviously used in a wide sense:—(1) Salpingitis cat. simplex or endosalpingitis; (2) S. diffusa or interstitialis, which comprises (*a*) S. hæmorrhagica and (*b*) S. follicularis. Of *purulent salpingitis* eight cases are described. In seven of these the most careful examination failed to detect any bacterial organisms—a negative result which suggests either that the organisms were remarkably scanty (as usual in chronic suppuration), or else that they could not be manifested by the methods used; reference, however, is made to the discovery by other observers of tubercle bacilli and of gonococci in tubercular and gonorrhœal salpingitis, and Dr. ORTHMANN himself has quite recently recorded an instance of the last-named variety.[1] In purulent salpingitis only traces of the ciliated epithelium remain where protected by the folds which are now converted into wide septa between cavities filled with pus; whilst the mucous membrane is more or less replaced by the granulation cells of the inflammatory process. In places the muscular coat may be laid bare by the destructive process. This coat may also be thickened by infiltration of round cells, and the vessels will be increased. In six cases the ostium abdominale was occluded, and of the others one had a fistulous communication with an ovarian abscess. There were two cases of *hæmatosalpinx*, in one of which there was atresia of the ostium abdominale, the mucous folds were stretched, and the wall somewhat atrophied. In the other case the tube was occluded by a kink. Four cases of *hydrosalpinx* are described, three of which were unilateral. In all the superficial epithelium was not much altered; in one case the mucous folds were hypertrophied, but in the

[1] Vide Berl. Klin. Woch., No. 14, 1887.

Digitized by Google

rest they were dwindled, and the muscular coat was also atrophied. Lastly, there were two cases of *pyosalpinx*, a condition generally dependent upon atresia of the tube. The walls were thickened and their vascular supply increased. No microbes could be found in the purulent contents. Dr. ORTHMANN also gives a summary of these cases, from which we gather that in the twenty-five operations there were three deaths—one from collapse and two from peritonitis. Of these cases twenty-one were simple salpingotomies (two deaths). In two instances the patient underwent a second laparotomy. In one a right hydrosalpinx was removed seven months after the extirpation of the left appendages; in the other, a large hæmatoma of the right ovary had been removed thirteen years before. The majority of the patients had presented no disturbance of menstruation; in five cases it had been of late somewhat profuse, in five there was severe dysmenorrhœa, and in three menstruation was irregular. The chief and universal symptom was pain in the abdomen and groin, whilst in ten cases there occurred hæmorrhage and in seven marked uterine discharge. As to the etiology of the cases, ten were ascribed to gonorrhœa, these including six purulent cases, two catarrhal, and the two cases of hydrosalpinx. Four were post-puerperal, but in the remainder no definite cause could be assigned. Two cases were associated with cancer of the uterus, one with myoma, and one with an ovarian cyst. The ovary was found diseased in all but two of the cases. In eight there was chronic ovaritis, two being further complicated with hæmatoma of the ovary and one with hydrops folliculorum. In four other cases there was ovarian hæmatoma, and in three others hydrops folliculorum, without other lesions. There were five cases of ovarian abscess, which in two cases communicated with the tube by small openings, and in one the tube and ovary were conjoined in a common abscess sac. One case of catarrhal salpingitis was associated with an ovarian cyst of the size of the fist. Atrophy of the ovary occurred three times, and parovarian cysts in four cases; in three cases there was hæmatoma between the ligaments, and in one an abscess. We have called attention to this contribution because it seems to us that the pathology of these conditions has yet to be worked out, whilst the material is rapidly accumulating for a thorough study of the subject.

DURING next week the General Medical Council will have to decide whether the Apothecaries' Society shall cease to exist as an examining body, or whether, by the appointment of assistant examiners in surgery, the special powers which they possess for protecting the public against unqualified practitioners shall be maintained. Of the issue there can be little doubt, however greatly we must deplore the multiplication of licensing bodies. There has not been from the first any question that the failure of the Colleges to unite with the Society is due to the action of the former alone; but if further argument were wanting, it is to be found in the rebuff which the Medical Council have themselves received at the hands of the Colleges, who have refused to comply not only with the request of the Council, but also with that of the greater number of their licentiates. We have no hesitation in saying that the governing bodies of the two Colleges have by their action lost the confidence of many of the profession, and we anticipate that evidence will not long be wanting of a determination to bring about the change which has hitherto been sought in vain. Until this is accomplished the Apothecaries' Society will continue to grant a separate licence to practise. By the appointment of assistant examiners the Medical Council will themselves be practically engaged in the duty of examining. A further business, moreover, which will occupy their attention is the appointment of inspectors of examination, and this will bring them still more closely into relation with this function of the corporations. Indeed, it is not impossible that in the future their powers in this direction may be increased until they have placed upon them a greater responsibility than that of acting as the critics of other people's work. Already they have adopted a resolution that the visitations and inspections shall systematically cover within stated periods of time the pass examinations in all branches of knowledge which the Council deem essential as qualifications for licence. Their intention is, therefore, to perform this duty in no perfunctory way, and although during the present year they will not go beyond the appointment of three inspectors, one each for medicine, surgery, and midwifery, it may be anticipated that it will not be long before every branch of medical examination is represented. The work of each inspector will be to attend the examinations of all the licensing bodies in the United Kingdom, so as to enable him to form an opinion upon and report to the Council as to their sufficiency or insufficiency. Evidence obtained in this manner will be the groundwork upon which future changes will be based, and it may be accepted that failure to protect the public from the entrance into the profession of unskilled practitioners will lead to the loss of powers to exercise this function. The selection of inspectors is therefore a matter of the greatest moment to the profession, and the Council may be trusted to exercise a wise judgment in their choice.

Annotations.

"Ne quid nimis."

THE LATE DR. WILSON FOX.

THE announcement of the death of Dr. Wilson Fox will cause widespread grief in the profession. A physician has passed away in the prime of working life whose knowledge, judgment, and skill had won for him a degree of confidence which few secure, and whose loss creates a void which cannot be easily filled. But this is not all. A man has passed away who was far more than a skilled physician. Dr. Fox combined in a degree rare in any calling moral elevation and moral courage, spiritual ardour and self-devotion. No consideration for his own interests warped his action from the straight line of right and honour, or dimmed the clearness of his mental vision. His intense energy has been a motive force in the profession of far wider influence than appeared on the surface, for he was ever ready to efface himself when the movement he had started had gained inherent strength. He will be deeply mourned, not only in the profession, but in a wide and ever-widening circle of those who knew him, and, knowing him, could not help entertaining towards him a feeling deeper than mere esteem, and warmer than mere gratitude. We hope next week to give some account of his life—a life of hard and earnest work, a

Digitized by Google

life of devotion and self-sacrifice, ending with the final sacrifice of himself, where so many have laid down their lives, on the altar of beneficence. To-day we give an account of his last illness.

On Saturday, April 23rd, Dr. Wilson Fox was in his usual health in London, and intending to proceed to his home in Westmoreland in the afternoon. His doing so was prevented by a telegram informing him of the serious illness of his eldest brother. He went into Somersetshire to see him, and found him suffering from acute double pneumonia and his case almost hopeless. He remained until his brother died on the following Wednesday, April 27th. During this time he had suffered from lumbago and some slight feeling of cold, but left for the north, stopping at Preston on his way. He was quite well when in Birmingham, and walked about there. At Preston he ate a simple dinner with thorough relish, and retired apparently quite well. Early in the morning he was disturbed, and sustained some chill amounting to a slight rigor. His temperature was raised, and he was seen by Dr. Brown of Preston, who found him suffering from pneumonia, with extreme cardiac weakness. During the day he was visited by Sir William Roberts, an old college and intimate friend, who took a very grave view of the case owing to the extreme cardiac weakness and his depression, the result of the death of his brother. He rallied in the after-part of the day. The temperature was never high. His cough was troublesome, and expectoration characteristic, not excessive. But very frequently there were recurrences of extreme cardiac dyspnœa, which were relieved by treatment. On Friday afternoon he was seen by Sir William Jenner in consultation with Sir W. Roberts, and the former remained with him during the night. His condition on Saturday morning was that which might be expected of pneumonia running its ordinary and natural course, but about 10 A.M. serious prostration (cardiac) reappeared, causing great alarm. Dr. Russell Reynolds was telegraphed for to come down immediately, which he did, and found that he had made some slight rally. The night of Saturday was passed with more comfort, and on Sunday morning, although suffering from some pleurodynia and lumbago pains and rapid breathing, he appeared better. About midday, after some intestinal disturbance, Dr. Fox became excessively prostrate. He was perfectly aware of the danger of his condition and took leave of his family. During two hours and a half death seemed imminent, but he occasionally rallied for a few minutes under subcutaneous injections of ether and the administration of stimulants and nourishment, which he took easily. During all this time there was considerable cyanosis. Later in the day he was better and passed a fair night, with some tranquil sleep, and on the morning of Monday the improvement was maintained. About midday, without apparent cause, his dyspnœa became most urgent, and it was found that he had mucous râles in the small bronchial tubes of both sides of the chest, with extension of lung congestion on the left side. From this, although from time to time there were periods of some relief, he did not rally, but occasionally, when dyspnœa was urgent, found great comfort from the hypodermic use of ether. His breathing did not trouble him, but cyanosis increased; he was perfectly clear in intellect, capable of understanding his own condition; but he became weaker and weaker every hour in spite of all that was done to aid him, and exactly at 4 A.M. on Tuesday he breathed his last, without any struggle or sigh. He had spoken with clear intelligence three minutes previously to Dr. Reynolds. Eleven years ago Dr. Wilson Fox had an attack of extremely acute pneumonia, and this was obviously of a rheumatic character, and extended to the pleura, pericardium, and endocardium. His life was then in grave danger during two or three days, and unfortunately both aortic and mitral valves were affected, but after a certain time of rest his recovery to all except those who knew the physical condition of his heart was complete. In the spring of 1886 another attack of pneumonia occurred after an accidental chill, when much depressed by the death of his mother, but the cardiac condition was again a source of extreme danger. From this he recovered, and was able to attend to his professional duties, and to exhibit, as all those who met him knew, an extraordinary amount of energy in work, mental and physical, professional and social.

The Court Circular of Wednesday contains the following: "The Queen was much grieved to receive yesterday the news of the death, after a few days' illness, of Dr. Wilson Fox, one of Her Majesty's Physicians in Ordinary. Dr. W. Fox had formerly been in frequent attendance on the Queen in Scotland, and Her Majesty had a great regard for him. The medical profession loses in him one of its most distinguished members."

THE ACTION OF THE DIAPHRAGM.

IN a memoir published in the just-completed volume of Braune's *Archiv für Anatomie und Physiologie*, Hasse gives the results of his observations and experiments upon this subject. He finds that the contraction of the muscular fibres of the diaphragm causes a flattening and descent of the diaphragmatic domes. The tendinous centre also descends, and becomes flattened by the traction exerted upon it from every side by the muscular fibres. In deep inspiration the descent of the diaphragmatic domes is always more considerable than that of the tendinous centre. The contraction of the muscular fibres of the diaphragm causes, as was maintained by Duchenne, an expansion of the lower aperture of the chest, owing to elevation of the ribs and of the sternum. When contraction of the muscular fibres of the diaphragm takes place, the muscular plane they form separates from the long walls of the thorax, and consequently cause an enlargement of the complemental space of the pleural sac; and to so much the greater extent the greater the coincident elevation of the thoracic cage. The descent of the diaphragm augments the normal positive intra-abdominal pressure, whilst its ascent diminishes the pressure, though never to zero. The changes of position which occur in the descent of the diaphragm cause a corresponding change in the position of the viscera lying subjacent to it—as the liver, stomach, and spleen. The liver is consequently by no means a rigid, fixed organ, but varies both in form and position. When the diaphragm contracts, the resistances to the flow of blood through the liver and spleen are overcome, and the passage of blood through them is rendered easier in proportion to the freedom of the respiratory acts. Lastly, the movements of the diaphragm are essential for the discharge of the bile, and further the movement of the contents of the stomach and intestines.

VACCINATION UNDER DIFFICULTIES.

THE Sultan of Turkey, it is said, has just had the ladies of the seraglio vaccinated, and we are told that the operation was attended with difficulties which fortunately are unknown in this country. An Italian physician who was employed to vaccinate the ladies of the harem was not permitted to see the faces of his patients, from whom he was separated by a screen. The operation, it is stated, was performed on the patients' arms, which were in turn thrust through a hole in the screen; and on every occasion of one arm being replaced by another, the physician was obliged to submit to his head being enveloped in a shawl, to prevent any chance of his seeing the subjects of his operation. The circumstances which permit the entrance of a man into a harem must be of rare occurrence, and probably there are none under which he is more welcome than when he comes to preserve the beauty of the inmates. Whether the Sultan has learnt by experience the necessity for vaccination, or

Digitized by Google

whether he is guided only by others, the fact remains that female beauty is more indebted to Jenner's discovery than to any art to which the sex can have resort. It has often been remarked that the portraits of ladies who were the English Court beauties of former times give no very exalted idea of the personal appearances which in those days merited approbation, and that the originals only excited admiration from the fact that they were among the few who escaped the disfigurement which attends an attack of unmodified small-pox. However this may be, we trust that the example which the Sultan has set will have its effect in leading to the more general vaccination of his subjects. There is nothing which more strongly impresses the traveller in the East than the large proportion of inhabitants who are scarred with small-pox.

THE DISTRIBUTION OF MICRO-ORGANISMS IN THE ATMOSPHERE.

THE interesting paper read by Dr. Percy Frankland at the Society of Arts on March 22nd will be found in the *Journal of the Society of Arts* of March 25th. In it he reviewed the history of the subject of atmospheric micro-organisms, by reference to the experiments of Pasteur, Tyndall, Miquel, and Freeudenreich. The introduction by Koch of solid cultivating media had, he pointed out, greatly assisted these investigations, and Hesse's method by the use of a glass tube coated internally with sterile gelatine peptone, through which a given quantity of air can be drawn by aspiration, had been largely used by Dr. Frankland. He pointed out, however, that the accuracy of this method depends somewhat upon the strength and direction of the air currents, and he had therefore devised a modification consisting in the introduction of glass porous plugs to retain the micro-organisms, the plugs being transferred to flasks containing liquid gelatine, in which, after cooling, the colonies resulting from the microbes later develop. The estimation of the abundance of microbes in the air is made by enumerating the number of colonies obtained in a given quantity (ten litres) of air thus filtered. Amongst the results stated may be selected the fact that from observation on the roof of the Science Schools at South Kensington the average number of colonies per ten litres of air varied from four in the month of January to 105 in August. On the top of Primrose-hill on May 19th, 1886, the average number of colonies was nine; at the foot of the hill it was twenty-four; at St. Paul's Cathedral the number in the air in the Golden Gallery was eleven, in the Churchyard seventy. In country places the air contained much fewer microbes than in towns, especially in crowded thoroughfares—there being, for instance, as many as 554 per ten litres in Exhibition-road on June 8th, 1886. Fischer's observations upon the gradually diminishing number of microbes in sea air in proportion to distance from land were shown to depend upon the direction of the wind, with the general conclusion that the maximum distance to which, under ordinary circumstances, micro-organisms can be transported across the sea, "lies between 70 and 120 sea miles, and that beyond this distance they are almost invariably absent." Records were also given of observations on the air of buildings, and upon the number of micro-organisms falling upon one square foot of horizontal surface in one minute. As to the nature of the aerial micro-organisms, the moulds were found to be most universally prevalent, being found generally in greater proportion to other forms at high altitudes in the open country. Numerous forms of micrococci and bacilli, especially chromogenous species, have been identified in the air; but, as regards pathogenic microbes, Dr. Frankland stated that their detection in presence of the overwhelming number of saprophytic organisms was almost hopeless. The air in a hospital ward, provided it be undisturbed, contains very few organisms, and the investigation points to practical hints in the prevention of any aerial commotion during surgical operations, and the great importance of removal of dust in a moist condition.

THE MEDICAL REGISTER.

THE Medical Register for 1887 has just been published. Its appearance this year has been delayed by the adoption, just before its final issue, of a suggested improvement, according to which initial headings at the top of each page enable the contents of each to be more readily seen. During the past year the work has been subjected to more thorough revision than in any previous year, circular letters of inquiry having early in 1886 been sent out to all practitioners, and in November voting-papers in connexion with the election of direct representatives to the General Medical Council. As the result of these inquiries, a very large number of corrections have been introduced. The statistical information contained in the volume will be found very complete, and in addition to the numbers being given of practitioners registered in the different divisions of the United Kingdom, the information is now supplied as to how many are resident in the three divisions. In the introductory part of the work the new Medical Act of 1886 has been printed, together with the older Acts, for the information of the profession, and a table of the qualifications in sanitary science that become registrable under the new Act is also inserted. Copies of the volume may be had, as in previous years, either at the office of the Medical Council or at the accredited publishers, Messrs. Spottiswoode and Co., 54, Gracechurch-street, E.C. The Medical Students' Register and the Dentists' Register for the current year have also been issued, and may be obtained at the same place.

MORTALITY AMONG RAILWAY SERVANTS.

NEARLY seven hundred millions of passengers travelled on railways in Great Britain last year, and of these eight were killed and 615 were injured in what are commonly called railway accidents. Many other persons not in the employ of the railway companies were killed or injured by accidents connected with the railway service, such as falling between carriages and platforms and the like; but, excluding servants of the companies, the total number of deaths from causes incident to railway travelling were only a trifle over 500, and of injuries only about 1500. Considering that these numbers include a great many casualties due to neglect of well-known precautions, we may conclude that, as regards passengers and the public, railway travelling is the safest mode of locomotion. But when we turn to the servants of the railway companies, the picture is not only less satisfactory, but almost appalling. We are not informed of the actual number of hands employed in the more dangerous kinds of railway work; but we are told that, including the railway carriers as well as the ordinary servants, there were last year 459 fatal and 5490 non-fatal accidents. Five men are killed on an average in four days, and sixty injured more or less severely. Whatever the number of workmen may be, this represents a very grave amount of injury to life and health, and the statistics prepared by the Board of Trade deserve the most serious consideration. Doubtless a large number of the casualties are due to the carelessness of the men. Familiarity with danger breeds indifference, if not contempt, and we all know by our daily railway experience how wilful platelayers, porters, and pointsmen are in running totally unnecessary risks. If a porter has to cross the line he seems to delight in waiting until the very last moment before the express dashes through the station, and in the same way the carman seems to choose by

Digitized by Google

preference a place exactly below the heavy weight which is being raised by a crane. A party of plate-layers, apparently with no one on guard, will continue their work with scarcely a glance up or down the line until a whistle reminds them that a train is close upon them, when they gather their tools and move out of the way quite leisurely. These things we have all watched with a feeling of irritable nervousness, and have, perhaps, from time to time admitted in our hearts that railway companies cannot be held morally responsible for the suicidal recklessness and stupidity of some of their *employés*. But, recognising all this, we fear that much real blame still attaches to the railway companies for the loose supervision which they exercise over the lives and limbs of their servants. Men constantly exposed to danger, even when, as often happens, they are not excessively overworked, are sure to become careless, and it is universally admitted that it is a part of the duty of employers to enforce due care upon their servants, as well as to diminish, as far as possible, the unavoidable risk they run. The protection of machinery in motion, the regulation of coal mines, and the inspection of ships, are all examples of the care which the State now bestows upon those engaged in dangerous industries. Economy of labour is probably, next to individual carelessness, the chief cause of the so-called accidents. It would surely be possible, without any great increase of expense, to arrange that in every party of men engaged in any particularly dangerous work, such as the shunting of trains or the repairs of the permanent way, one man, experienced and worthy of trust, should have some responsibility for the safety of the rest. He would be a foreman, and if any disaster due to negligence happened to one of his gang, a greater or less degree of blame would attach to him. No doubt he would individually do less manual work, but probably the work would be better done, and at any rate, if sufficient authority were committed to him, he would in many cases save the men under him from the results of their own ignorance or indiscretion. When Parliament finds time for domestic legislation, we hope it will endeavour to minimise the risks run by a useful body of public servants.

FUNCTIONAL DYSPEPSIA AND ITS RESULTS.

DR. JAWORSKI has investigated, chiefly with respect to the relative amount of hydrochloric acid secreted, the composition of the gastric juice in 222 individuals who presented symptoms of gastric disturbance, yet in whom there was no evidence at all of organic disease of the stomach. His observations have led him to differentiate five groups, or rather stages, of functional derangement (*Wien. Med. Woch.*, 1886, Separatabdruck). In the first, under the influence of repeated irritation of the gastric mucous membrane, as by brandy or condiments, the sensibility is increased to a degree that during digestion there is developed an abnormal secretion of hydrochloric acid, which may give rise to subjective gastric disorder as well as remote nervous symptoms. The condition, he says, is readily recognised, and is declared to be nervous dyspepsia, but it actually forms a prodromal stage of more permanent derangement, for in the next stage he finds that the acid is secreted continuously and spontaneously even in the empty stomach, the quantity increasing during digestion. These cases are marked by gastralgia and vomiting, and the mucous membrane is, one may say, subinflamed. This condition may, under continued irritation, pass into a third stage, when the acid secretion is extremely abundant, being as high in the intervals of digestion as during the process. Often bile finds an entrance into the stomach, and under the action of the acid is converted into the characteristic greenish-yellow flakes. The gastric epithelium is acted on, being shed in masses and in layers. The condition leads, as may well be imagined, to dilatation of the stomach, partly from weakening of the walls, and partly from incomplete evacuation, with fermentation of the food débris. The symptoms are those of intense gastric discomfort after taking food, with retention of appetite. The excessive thirst can only be allayed by warm drinks. Ultimately an anæmic state is developed. The condition may be termed "hypersecretio hyperacida continua," or "gastrorrhœa acida," or, anatomically, acid catarrh of the stomach. It seems to accompany most cases of gastric ulcer. After this extreme condition of irritation has lasted a certain time, there occurs a diminution of the secretion of hydrochloric acid, and the mucous membrane gradually loses its sensibility to stimuli. This the fourth stage (or type) of functional disorder is characterised by feebly acid or even alkaline reaction of the gastric juice, and, anatomically, it is marked by gastric dilatation. It is the condition which patients style "a weak digestion," and it is attempted to be corrected or arrested by stimulating foods and drinks; but these efforts often cause the case to pass over into the fifth or last stage of the series. Here we have a total incapacity of the stomach to secrete acid, and in great part also a loss of pepsine-forming power. No stimulus can excite the acid secretion. The stomach contains a small quantity of mucoid, cloudy, mostly alkaline fluid, of no peptonising power. Yet the patients may be well nourished and not always anæmic, intestinal digestion still being in action. The condition, "mucous catarrh," is that which accompanies most cases of gastric carcinoma.

SMALL-POX AT CARDIFF.

OUR attention is drawn to the prevalence of small-pox at Cardiff, and to the action which is being taken in consequence. According to the *Western Mail*, arrangements have been made that the public vaccinators shall attend at their own residences every evening at a certain hour, so that the working classes may have an opportunity of securing revaccination, and that on receiving notice of the existence of small-pox in any house, the public vaccinator for the district shall proceed to that house, and there offer vaccination or revaccination, as the case may be, to all the inmates. On the part of some it is thought that further action should be taken, and that a house-to-house inquiry should first be made, this being followed by the offer of vaccination at their homes to all who need additional protection. The house-to-house inspection suggested is of the utmost value, and it has on several occasions brought about the best results—as, for example, in the St. Pancras outbreak of 1884. But as regards the expediency of taking vaccination away from the stations where a proper supply of lymph from infants is alone obtainable, except under such special emergencies as the existence of small-pox in a house, grave doubts may be entertained. That some immediate good would result we do not doubt, but, after all, it is the full protection of the general population by efficient vaccination that must be the main aim of the guardians, and not the spasmodic gift of an inferior vaccination on a large scale at moments of panic. House-to-house vaccination must necessarily be largely performed otherwise than from arm to arm, and it is notorious that vaccination so done is, as a rule, less efficient than when the lymph is taken direct from an infant's arm, and that it tends in the end to bring vaccination into disrepute. It therefore becomes a question whether the main gain would come from a large increase in the amount of vaccination irrespective of quality, or from a limited amount having true protective qualities. We have looked at the memorandum issued by the Local Government Board on this subject, and we find it entirely supports the view that the current work from arm to arm at the stations should, even in moments of emergency, not be sacrificed to sudden demands arising out of a previous neglect to secure efficient protection.

REGINA v. BAXTER AND POTTS.

ON April 28th and 29th the trial of Mr. Baxter, an unqualified medical assistant, and Mrs. Potts, described as a midwife and ladies' nurse, for having procured illegal abortion on Elizabeth Culling, aged twenty-two, took place at the Old Bailey before Mr. Justice Stephen. The jury convicted the prisoners, who were sentenced each to fifteen years' penal servitude. There was a committal by the coroner on the capital charge, but this was abandoned by the prosecution, and the prisoners were indicted only on the minor count of felonious assault, as it was considered doubtful if the evidence would suffice to warrant a conviction on the charge of murder. The facts of the case are already known, so that it is not necessary to give them in detail. The deceased, a single woman, ostensibly an assistant in a confectioner's shop, but who appears to have led a "gay life," resided at a private hotel in London-street, Paddington. As alleged by the prosecution, she went to reside with the female prisoner for the purpose of having an abortion procured. The evidence went to show that she was attended by Baxter, who was known as "the doctor" and as the husband of Mrs. Potts, but, as a matter of fact, he was neither one nor the other. Some days after the abortion took place, finding deceased in an apparently hopeless condition, one or both of them took her to the Paddington Infirmary, where she died the day after her admission. The acting medical officer of the infirmary, together with his colleague, made an unofficial post-mortem examination. From this they learned that deceased died from acute peritonitis and blood poisoning consequent on a recent abortion. They also detected two deep grooves or puckerings in the neck of the womb. Subsequently, by order of the coroner, a further examination of the body was made by Mr. Pepper, assisted by Dr. Smith. These gentlemen ascertained that the so-called puckering in the cervix were two deep lacerated wounds half an inch deep extending for the whole length of the cervix. They were further of opinion that the rents had been made some days before death. A portion of the placenta corresponding to a four months' pregnancy was still firmly adherent to the fundus uteri. There were no injuries to the body of the womb, nor to the vagina or external genitals. No natural cause of abortion was discovered. At the fourchette and for some distance up the vagina were some "gonorrhœal warts," but no signs of syphilis were to be seen. A few days before her death deceased had been treated at the Lock Hospital for vaginitis. The theory set forth in the prisoner's defence was that the abortion was a consequence of the death of the fœtus, and that this was due either to syphilis or to inflammation having spread from the vagina to the uterus, or to blood poisoning from absorption of the vaginal discharge. The medical men who gave evidence for the Crown admitted that these were all possible causes of abortion, and that syphilis was a very frequent cause. They further admitted that natural abortion is a not unfrequent event from causes other than those above enumerated, but they declined to subscribe to any definite percentage of abortions in a given number of conceptions. In this they were undoubtedly right, as authorities on the subject differ very widely in their estimates. Mr. Justice Stephen, who was of the same mind, told the jury that, medicine being an inexact science, it was difficult to obtain absolutely trustworthy statistics on account of the difficulty in obtaining all the facts in the inquiry. A point of some importance was raised concerning the post-mortem evidence of syphilis. Mr. Pepper admitted that it was just possible that a person might have been the subject of the constitutional affection, and yet that at a necropsy no conclusion of the existence of the disease might be found. Mr. Bloxam deposed that, in his opinion, if syphilis were present it would be discovered, since the lymphatic glands remain enlarged so long as the patient suffers from the disease. The latter statement is no doubt quite correct; but would one be justified, upon finding enlarged glands apart from other signs of syphilis, in concluding that the deceased was the subject of syphilis? Whatever may be the surgical interpretation of the question, it was obviously safer to give the prisoners the benefit of the doubt implied by the difference of opinion expressed at the trial. Apart, however, from the medical evidence, the collateral testimony—circumstantial and direct—told strongly in favour of the guilt of the accused. Before Justice Stephen passed sentence Mr. Poland informed him that the Treasury were in possession of information that the convicts had illegally procured abortion in other cases.

CARBOLATE OF MERCURY IN SYPHILIS.

DR. KARL SHADEK of Kieff, being anxious to try the effects of carbolate of mercury, which has been strongly recommended in syphilis by Professor Gamberini, requested M. H. Brandt, a pharmacist in Kieff, to prepare some for clinical use. This he did by precipitating a very dilute solution of bichloride of mercury with a concentrated alcoholic solution of carbolate of potassium. A yellowish precipitate was obtained, which, after being frequently agitated with the liquid for twenty-four hours, assumed a whitish appearance. It was filtered and washed with distilled water till the washings showed no traces of chloride. It was then transferred to a fresh filter paper and dried under a bell jar. In this way a nearly white tasteless amorphous substance was obtained, which was scarcely acted upon or dissolved by cold, but was readily soluble in boiling, hydrochloric acid. The name given to it by Dr. Shadek is "hydrargyrum carbolicum oxydatum," and he has been using it in his private practice for several months. At first he gave it in the form of pills, one of which, containing about an eighth of a grain, was ordered three, or occasionally four, times a day. It was well borne, and did not interfere with the digestion. In some cases the treatment was continued for six or eight weeks, without producing colic or other disagreeable symptoms. The total number of syphilitic cases in which it was given internally was thirty-five (twenty-six men, six women, and three young children). In five of these there was swelling of the gums and salivation. Mercury was found in the urine after the third dose. Its therapeutic value was especially remarkable in macular and tubercular syphilides and in syphilitic psoriasis of the palm and the sole. Syphilitic rash and slight relapsing forms yielded to the treatment in from two to four weeks; in syphilitic affections of the mucous membrane, and in papular and pustular eruptions, from four to six weeks were required. Multiple enlargements of glands were but little affected by it. In the case of children of from two to four years old, doses of about the fifteenth of a grain were well borne twice daily.

THE DECAY OF BODILY STRENGTH IN TOWNS.

OTHERS besides Lord Brabazon must have remarked the steady flow of population which has set in, especially of late years, from the country districts to the towns, and must have asked themselves, as they reflected on the changed conditions, the high working pressure with intermissions of enforced idleness, and the unwholesome home life which awaited many of those immigrants, how far in the end the nation would be a gainer by the interminable process. So long as our manufacturing and shipping industries continue to maintain a fair measure of prosperity there is little likelihood that the influx into the towns will be seriously checked. Its influence for good or evil on the physical state of our

Digitized by Google

people must therefore greatly depend upon our securing for them in their changed mode of life the surroundings necessary for healthy development. It would be difficult to show by precise statistics how far the work of degeneration has progressed among our poorer urban population. For our own part, we are not disposed to accept, without due scrutiny, any random alarmist rumours as to a progressive shortcoming in the national vigour. It must, however, be generally allowed that until a recent date little care has been taken to protect the poorer inhabitants of our cities against the evils of overwork, overcrowding, mismanagement in household arrangements and in food and drink, and other insanitary conditions to which they are almost necessarily subject; and if this negligence be allowed to continue, the logic of facts will not fail to convince us of a suicidal error. There is therefore good reason why schemes now on foot for the better housing of the poor, the better allotment of working time, and plans which like these tend to healthy living should not want substantial support. We would also draw attention to the great importance of care in the physical training of children, by rendering gymnastic exercises a compulsory part of education, and we are reminded by another article in the *Nineteenth Century* that sufficient attention has not been paid to the necessity for leaving here and there in districts extensively built upon open spaces for public recreation. Where common land is not available, it might well become the Legislature to order the allotment of certain portions of enclosed land for this purpose.

THE MEDICAL ACT, 1886.

FROM the frequent inquiries that have been addressed to us, there appears to be some doubt as to the effect the new Act will have on practitioners whose names are now registered. It may therefore be as well to point out that gentlemen whose names are now upon the Medical Register will not have to re-register. Existing single diplomas not yet registered—as, for example, the M.R.C.S.—can be registered up to Tuesday, May 31st, after which date degrees and diplomas cannot be registered, unless they have been conferred after a qualifying examination in medicine, surgery, and midwifery, held expressly for the purposes of, and under the conditions stated in, the Medical Act of 1886. The Act, however, gives power to the Privy Council to postpone "the appointed day" to any day not later than the end of June—a power on the exercise of which, we have reason to believe, the Medical Council is likely to be consulted at their meeting next week.

ANTISEPTIC MIDWIFERY.

IN a report by Dr. K. Inoieffs of the work done in the Lying-in Institution in connexion with the Golitsinski Hospital in Moscow for the year 1886, the advantage of antiseptic midwifery, which is strictly carried out there, is evident, as out of 541 cases there were but 2 deaths. Some of the statistics, which are very carefully kept, may be of interest. The largest number of births occurred, as it is popularly believed they do, at night, 145 taking place between midnight and 6 A.M.; the numbers corresponding to the remaining three-quarters of the twenty-four hours being 131 from 6 A.M. to noon, 107 from noon to 6 P.M., and 144 from 6 P.M. to midnight. There were 14 abortions and 9 cases of twins; three births took place in the street. Of the remaining 501, 478 were vertex presentations, 15 breach, and 8 transverse. In 9 of the 14 cases of abortion the ovum was removed mechanically. When there was considerable hæmorrhage and the os was not dilated, a hot vaginal injection of carbolised water was given which was, as a rule, successful. Twice, a plug consisting of a long strip of cotton-wool moistened with glycerine and iodoform was introduced by means of the speculum, as much as possible being inserted into the cervical canal, and subsequently, when the os was sufficiently patent, the finger was introduced and the uterine contents removed. In one case there was a slight amount of perimetritis and in two a single rise of temperature. In one case a spatula was cautiously used to assist the irrigation, and once the contents were removed with the help of a sharp hook. Apart from cases of placenta prævia and abortion, there were 29 cases of hæmorrhage, 6 of these occurring in primiparæ; six took place during the first and second stages of labour, the rest in the third stage and post-partum. The treatment adopted was, during the first stage, to plug, and when the os was sufficiently dilated to rupture the membranes. If there was rigidity of the os, narcotics were given. When uterine atony was the cause, massage, the application of ether to the abdomen, hot injections, and (after the birth of the placenta) ergot were resorted to. As to operations, episiotomy, or a double V-shaped incision of the perineum was performed five times, no sutures being inserted afterwards. Twice the os uteri was incised; twice the prolapsed cord was replaced; perineal sutures were required in 20 cases. In the performance of the operation the most careful antiseptic precautions were taken; in 16 cases the union was complete. Retention of membranes required the introduction of the hand into the uterus once, but in 14 cases the placenta had to be artificially extracted, being completely adherent once, and partially so thirteen times. Labour was induced prematurely for contracted pelvis three times, twice by the injection of water at 28° R. (95° F.) through a tube passed into the cavity of the uterus, between the uterine wall and the fœtal membranes; in the third case it was induced by the introduction of an elastic sound into the uterus. Podalic version was performed eleven times, and the forceps applied fifteen times. Craniotomy was performed twice.

REPORT ON FACTORIES AND WORKSHOPS.

THE annual report of the Chief Inspector of Factories and Workshops is, as usual, of considerable interest. We are pleased to note that it speaks encouragingly of a revival of trade in nearly all branches of industry, which was particularly noticeable towards the end of the year. Of the many industries in which an improvement is noted, we are glad to find the linen trade is in a flourishing condition, as likely to encourage the growth of flax in this country, a matter of considerable importance to agriculturists in these depressed times. The invention, too, of a new scutching machine, by which 30 per cent. of fibre may be secured from the straw instead of about 20, will also aid in this direction. But the chief interest in the report, so far as we are concerned, is contained in the information it affords respecting the precautions taken in various industries to protect the workpeople from injury or loss of life or health. The total number of accidents last year arising from machinery alone amounted to no less than 6656, of which 316 were fatal—a formidable return, but one which, we are pleased to find, is gradually diminishing owing to precautions enforced and by improvements in the construction of the machinery employed. Thus many accidents occur from unfenced hoists, and these are generally serious; Mr. Meade King in the report deals at length with this, and introduces us to several kinds of hoists which, whilst simple and inexpensive, protect the employed from accident and the employer from liability. Mr. Lakeman, another inspector, has devised a saw guard, which is calculated to prevent those serious accidents that so frequently occur from the use of the circular saw. Mr. Lakeman has also induced Mr. Rockhill

Digitized by Google

to perfect a system for stopping shafting and machinery instantly, so that a person caught by machinery can immediately be released. The ventilation of factories and workshops receives considerable attention, and several effective and simple methods suitable to small factories are described. We regret to find that the enactments of the Truck Act are still evaded in some districts. One of the inspectors, Mr. Hoare, states the following as of recent occurrence. "A chain-maker informed me this week that he paid his master 15*s.* for gleeds which he could buy for 7*s.*" The enormous profits made by the employers by selling gleeds enables them to sell common chains at cost price, to the great injury of the workman, who, in addition to his loss on the transaction, is fined if any of the links are the least faulty. One wonders that the workmen, in their own interests, allow such a system to continue. But it is, in reality, a question of work or no work, and any complaint on their part leads not only to their present discharge, but prevents their getting employment in the future. It is satisfactory to note that the prosecutions for offences against the Factories and Workshops Act are not for very grave breaches of the law. Still, they are numerous enough to show that in the absence of constant supervision very grave abuses would speedily spring up. Fortunately, the character of this report assures us that the inspectors are keenly vigilant, and, moreover, are themselves interested in the work and ready to receive and to suggest anything that will improve the conditions of health and add to the security of life and limb in our workshops and factories.

THE MEDICAL SOCIETY OF LONDON.

THE annual Oration (which we publish in another part of our present issue) was delivered by Sir Wm. Mac Cormac at the commencement of the conversazione on Monday last, Dr. Hughlings Jackson, F.R.S., President, in the chair. Sir Joseph Fayrer proposed, and Mr. Croft seconded, the vote of thanks to the orator for his interesting address on Abdominal Surgery. The conversazione was, as usual, a great success, the music being provided by the string band of the Royal Artillery. Specimens of art pottery, by Messrs. Martin Brothers; recent etchings and mezzotints, by Mr. R. Dunthorne; photographs of landscapes, by Mr. Vernon Heath; Japanese screens, by Mr. W. Anderson, F.R.C.S.; oil paintings and water-colour sketches, by Mr. G. E. Cook; book of engravings after Rubens and Vandyck, by Mr. Walter Pye, F.R.C.S.; the Remington Standard Type-writer, by Messrs. Wyckoff, Seamans, and Benedict; together with some old books, including the MS. of the Rev. John Ward, which contains the only authentic account of the cause of Shakespeare's death, besides other objects of interest, were provided for the delectation of the Fellows and their friends. We may add that the entrance hall, staircase, and rooms were lighted by the patent safety lamps of Messrs. Defries, which had been lent for the occasion.

PYORRHŒA ALVEOLARIS.

MR. NEWLAND PEDLEY, F.R.C.S., read a paper at the Odontological Society upon the above subject. Pyorrhœa alveolaris is characterised by conditions as follows:—The mucous membrane, especially that adjacent to the teeth, is deeply congested, tumid and thickened, and detached from the necks of the teeth and from the roots. A thick fetid discharge may often be pressed up between the teeth and mucous membrane, which gives to the breath a very repulsive odour. Later, the alveoli become absorbed, and at times more or less denuded, whilst the fangs of the teeth become coated with a layer of thin, hard, green-brown tartar. Ultimately, the disease progressing, the teeth, one after another, drop out. The pathological changes which take place are hypertrophy of the muco-periosteal fold around the teeth, accompanied by dilatation of capillary loops, enlargement of the papillæ, and rapid proliferation of epithelial cells. Later the gum becomes firm and contracted, and displays increase of fibrous tissue. The changes which go on in the socket have not been yet satisfactorily worked out, but the examination of the jaws of some carnivora which were apparently affected with pyorrhœa alveolaris would lead to the supposition that there is osteitis of the alveolar process spreading towards the apex of the socket. There are many differences of opinion as to the causes: some maintaining that it is of parasitic origin and due to a specific bacillus, but there is no good proof of this; others that it is catarrhal, and an extension of inflammation of the mucous membrane; others that it is due to the irritation of small deposits of hard tartar under the edge of the gum, but this is plainly not the case, for the disease may be far in advance of the deposit, and in some cases there is not any to be found. It is probably due to some constitutional condition, and the fact that it is often symmetrical, and frequently hereditary, gives support to this view. It occurs in the mouths of patients whose health has been undermined by debilitating influences and injudicious habits of living; it is a common sequel of malarial fever in America; young persons recovering from eruptive fevers are sometimes subjects of pyorrhœa alveolaris; and frequent pregnancies are a fruitful source of the disorder. Attention has been lately drawn to the shedding of the teeth in tabes dorsalis, but it does not by any means seem to be a constant symptom. Mr. Bland Sutton has found that premature loss of the teeth is a very common feature in cases of rheumatoid arthritis in animals, and has also met with it in mollities ossium and other wasting diseases. Magitot, who views the alveolar-dental periosteum as a ligament, and not of the same nature as osseous periosteum, calls the disease symptomatic alveolo-arthritis, and mentions especially as causes chronic Bright's disease and glycosuria, in which latter, he says, the phenomenon is absolutely constant.

THE POPE ON ALCOHOLISM.

LEO XIII., even more than his predecessor Pius IX., has made the social amelioration of the masses an object of Catholic concern, mobilising the forces of the Church and even calling on public hygiene to assist in the philanthropic crusade. The ravages of intemperance, particularly in the United States of America, have just evoked from him a strenuous charge to the clergy in that part of the world to continue their efforts for the removal of the scourge, and to make their flocks an example of moderation and sobriety to all outside the fold. In a Brief addressed the other day to Monsignor John Ireland, Bishop of S. Paul, Minnesota, he congratulates him on the success which has followed the organising of the Catholic Union for the observance of total abstinence (*Unio Catholica perfectæ abstinentiæ sequendæ*), and adds that too much praise cannot be given to those pastors in the United States who in the late plenary council at Baltimore have formulated a "plan of campaign" against the abuse of alcohol, with its bequest of disease and misery to generations yet unborn. He commends the Bishop and his clergy for themselves reinforcing their precept by personal practice, and charges them zealously to save their Church and their native land from the innumerable calamities with which both are menaced by the vice of alcoholic excess (*ut tot calamitates ex eo vitio Ecclesiæ ipsique patriæ impendentes strenue avertere contendant*). The Catholic Union, to which the Pope alludes, now numbers over one hundred thousand members, while it is at the same time gratifying to hear that the co-operation of the medical profession in what is nothing less than a great movement, sanitary as well as social, is also noted with commendation

Digitized by Google

at the Vatican. The Church, whether Catholic or Protestant, in a cause so humanitarian, may always count upon medicine and its practitioners for loyal and effective support.

MEDICAL OFFICERS OF HEALTH.

THE Sanitary Authority of West Ham had last week under consideration the question whether they should appoint a medical officer of health who should devote the whole of his time to the district, or whether they should elect a medical man who had other means of adding to his income. The Sanitary Committee had recommended that the former course should be adopted; but the Town Council sitting in committee had not approved this recommendation, and the corporation have now by a small majority rejected an amendment that an officer be appointed who should give the whole of his time to his duties. This decision is distinctly unfortunate. In a district of the size and population of West Ham there is abundant material for the work of one man, and in engaging a partial service the corporation are by no means doing the best for their borough. There is only one reason for satisfaction to be found in this decision. If the feeling of the corporation is to be judged from the statements of its members, the inadequate remuneration of £300 a year would be given to the officer, who would be expected to devote a special knowledge of preventive medicine and the whole of his time to the health duties of West Ham. It is needless to add that this sum ought to be, and would be, insufficient to procure for the corporation the services of anyone fully competent to perform this important duty. West Ham should have learnt by its own experience the necessity for active sanitary administration, and it is to be regretted that the corporation should now be prepared to leave the borough without the aid of an officer of the best professional standing.

THE INFLUENCE OF TEA, COFFEE, AND COCOA ON DIGESTION.

DR. JAMES W. FRASER, in the recent number of the *Journal of Anatomy and Physiology*, has recorded the results of an interesting series of experiments on the action of our common beverages on stomachic and intestinal digestion. The experiments have been most carefully arranged from a physical standpoint, and give us some valuable hints on the digestion of the chief alimentary principles, but they have no bearing, it should be mentioned, on individual variations of human digestion, or on the influence of the various glands in preparing the gastric or intestinal juices. They are, however, of much value in showing how standard preparations of the peptic and pancreatic ferments are modified in action when our ordinary daily beverages are allowed their free action on the digestion of various articles of food. The digestive processes were carefully investigated, and absorption was imitated by a proper dialysing arrangement. An artificial peptic juice, and afterwards an artificial pancreatic juice, were employed, and the amount of nitrogenous matter dialysed was most carefully estimated. The food stuffs experimented on were raw and cooked serum and egg albumens, raw and cooked myosin, syntonin, alkali albumen, casein, gluten, starch, and oleine. The results obtained from an exhaustive series of experiments and analyses show that all the three typical infused beverages—tea, coffee, and cocoa—retard the digestion and absorption of all the nitrogenised proximate principles of dietetic substances when peptic and pancreatic digestion are taken together, and that they uniformly retard peptic digestion, although tea may assist the diffusion of peptones from the stomach. Pancreatic digestion is also uniformly retarded, and diffusion thereafter is but rarely assisted, so that neither of them compare advantageously with water as a standard beverage for experimental investigations. A summary of dietetic advice is added to Dr. Fraser's observations, which will, in the main, agree with that which is now given by our best authorities in cases of dyspepsia; and we are glad that experimental inquiries afford so strong a basis of support to empirical clinical observations:—

"1. That it is better not to eat most albuminoid food stuffs at the same time as infused beverages are taken, for it has been shown that their digestion will in most cases be retarded, though there are possibly exceptions. Absorption may be rendered more rapid, but there is a loss of nutritive substance. On the other hand, the digestion of starchy food appears to be assisted by tea and coffee; and gluten, the albuminoid of flour, has been seen to be the principle least retarded in digestion by tea, and it only comes third with cocoa, while coffee has apparently a much greater retarding action on it. From this it appears that bread is the natural accompaniment of tea and cocoa when used as the beverages at a meal. Perhaps the action of coffee is the reason why, in this country, it is usually drunk alone or at breakfast, a meal which consists much of meat, and of meats (eggs and salt meats) which are not much retarded in digestion by coffee. 2. That eggs are the best form of animal food to be taken along with infused beverages, and that apparently they are best lightly boiled if tea, hard boiled if coffee or cocoa, is the beverage. 3. That the casein of the milk and cream taken with the beverages is probably absorbed in a large degree from the stomach. 4. That the butter used with bread undergoes digestion more slowly in presence of tea, but more quickly in presence of coffee or cocoa; that is, if the fats of butter are influenced in a similar way to oleine. 5. That the use of coffee or cocoa as excipients for cod-liver oil &c. appears not only to depend on their pronounced tastes, but also on their action in assisting the digestion of fats."

A JUBILEE SUGGESTION!

MR. T. W. RHYS DAVIDS has written to the *Academy* to suggest that the Jubilee of the Queen and the Jubilee of the University of London may best be celebrated by changing the present title of the University to that of the "Imperial University," because it is an "Imperial Examining Board." And yet we are supposed to believe that the *Academy* is a serious and severely critical paper, and that its correspondents are really in earnest, even when they make such an audacious proposal as this must seem to the authorities that be. Surely the writer must be intent on indirectly advocating a Teaching University for London, although we do not find his name among those who support the movement.

BURIAL DURING A TRANCE.

THE reading public have lately been startled by the shocking details of a reported case of burial during a state of trance. The history of this occurrence—which relates how a Russian officer was interred in his family vault forty hours after his supposed death, and how his body was found a fortnight later turned with the back upwards in his coffin, the lid of which had been partly forced open, with face torn, and hands gnawed and still bleeding—appears too horrible to be true. Instances of living burial have at various times been reported. The authenticity of some such has been vouched for on good authority, though even these, it may be, have not reached us without the spectral halo of an oft-repeated horror. Some others, which owe their apparent credibility to the signs of movement due to cramp-like spasms occurring after death, may probably be dismissed at once as fictitious. We would fain hope that the most recent and appalling case, to which we have referred, is one of those to which excited popular imagination has added, as it is wont to do, particulars as dreadful as unfounded.

Digitized by Google

It is certainly somewhat difficult to understand how a human being could live for a fortnight, shrouded, and in the confined space of a coffin, without nourishment of any kind, without fresh air, in a state of trance, and awake at the end of that time possessed of sufficient strength to struggle desperately and to lacerate himself as this unfortunate officer is said to have done. As a matter of fact, moreover, it is hardly conceivable that the eye of a careful and educated observer should mistake the true meaning of the collective signs of death or fail to note their absence in a case of stupor, however death-like to the ordinary onlooker.

ON THE VALUE OF THE HÆMORRHAGE IN THE TREATMENT OF WOUNDS.

PROFESSOR TURAZZA, in the *Gazzetta degli Ospitali* of April 13th publishes a note showing that hæmorrhage from wounds, when not due to the lesion of large vessels or carried to excess, is of small importance and does not interfere with primary union. He believes that the rule generally laid down regarding the first dressing of a wound—viz., to secure complete arrest of hæmorrhage and to apply firm compression—though excellent, is not important. Professor Turazza relies on perfect disinfection of the bleeding surface, as far as within reach, by means of weak solutions of phenic acid or corrosive sublimate. He then leaves the cavity of the wound full of blood, without any doubt as to primary union, the edges of the wound being very accurately sutured. As the result of his experience he formulates a new rule in surgery—"that in wounds perfectly disinfected and free from foreign substances the effusion of blood is not a source of danger, but the reverse, for the extravasated blood fills up the cavity of the wound perfectly, preventing the formation of empty spaces and rendering both compression and drainage superfluous, and, further, the organisation of the clot favours healing." Professor Turazza also expresses himself decidedly averse to the use of the drainage-tube, because it increases septic risks, and may remove from the cavity into which it is inserted fluids which in an aseptic condition may be useful by reabsorption. He advises the restriction within the narrowest limits of the drainage-tube, and would deprecate its use in even ovariotomy, hysterectomy, and amputation of the breast, thinking it more dangerous than useful.

THE INCOME OF DOCTORS.

OUR contemporary the *Graphic*, accepting the estimate of Dr. Thurstan in our columns, that the average income of medical men does not much exceed £300, or, including house-surgeons, ship surgeons, and assistants, even £200, recommends as a—if not the only—remedy, combination. This remedy is one that medical men are not fond of. There is something in the very nature and property of the profession which deters its members from combining to decline help to those in need. But it may be tempted to try the ways of less sensitive classes. There is so much shabbiness in the remuneration of medical services. In many people, and in some classes of the community, there is such a determination to treat medical services ungenerously that it would do good to combine. It would lead to a more wholesome estimate of the value of medical service and advice. It would correct the vulgar impression that people have a sort of natural claim on doctors at any hour of the day or night. No doubt it would cause some surprise, not to say scandal, if the whole profession were to unite to decline to answer the call of those who see no necessity to pay doctors, but think doctors bound to attend them. But a little reflection on the part of reasonable people would soon lead them to a more correct judgment. The difficulty is, as our contemporary says, in getting combination among medical men. There is so little organisation and so much competition that the patient who owes a medical bill to one doctor is only too sure of being able to secure the services of another, and, when he fails to be reckoned with, of a third medical man.

THE COMPULSORY ISOLATION OF INFECTIOUS PATIENTS.

A CASE has just arisen at Gosport which illustrates a difficulty that has more than once occurred in the administration of the clauses of the Public Health Act which deal with the spread of infectious diseases. Under Section 124 of that statute it is enacted that, where a sanitary authority have provided an infectious hospital, they may, by order of a justice who acts under a medical certificate, remove to that hospital any person who is suffering from any dangerous infectious disorder. But amongst the conditions necessary to the procuring of the order it must be shown that the person in question is "without proper lodging and accommodation"; and it is the precise meaning of this condition that gives rise to difficulty. On the one hand, it has been contended that since the statute deals with public rather than individual health, and since the intention of the section in question is clearly indicated by the heading "Provisions against Infection," under which it is placed, the quality of the accommodation referred to has to do not so much with the welfare of the patient as with the risk of danger to others. But, on the other hand, it is held that since the section admits of the compulsory removal, quite apart from the question as to the quality of the accommodation in so far as this may affect others, in cases where the patient is in a room occupied by more than one family, or is on board any ship or vessel, the reference to proper lodging and accommodation has to do with the welfare of the patient, and not of the public, apart from the two exceptional conditions specified. The latter has generally been the customary ruling of magistrates, and it was so in the case which has just arisen. A young woman, who was a tailoress and who lived with her mother, was found to be suffering from small-pox at Gosport, and in the house were twelve pairs of trousers she had made for the Marines. The danger to others was obvious, both owing to the locality and circumstances under which the patient was placed and owing to the special nature of her calling. But the magistrates, ascertaining that the quality of the accommodation, especially as to cubic space, which was available for the sick woman in her own house was sufficient for her own proper treatment, decided that they had no power to order her compulsory isolation in the hospital tents provided by the sanitary authority. This case indicates the legal aspect of this compulsory removal clause; and, as far as we are aware, there has been no appeal against the position which the magistrates have taken up, either on this or on other similar occasions. Fortunately, the isolation of the infectious sick is but rarely dependent on the exercise of compulsory powers. Where a really proper hospital, of a reasonable attractive character and with good administration, is provided, hundreds of persons are every year only too willing to avail themselves of the advantages thus afforded to them.

THE MORTON LECTURES ON CANCER AND CANCEROUS DISEASES.

SIR JAMES PAGET, at the unanimous request of the Council of the Royal College of Surgeons, has consented to give the first lecture on Cancer and Cancerous Diseases at a date to be announced later (in all probability towards the close of the year). The lecture will be the first given on the above subject in compliance with Mr. Morton's donation.

THE UNIVERSITY OF LONDON.

THE annual meeting of Convocation of the University of London will take place on the 10th inst., when the report of the Annual Committee will be presented. Although the scheme for the reconstitution of the University proposed by the Special Committee of the Senate has been circulated as an appendix to the report of the Annual Committee, there is no resolution on the agenda in reference to it. It remains to be seen whether the subject will be discussed at this meeting. Probably some notice may be taken of the matter on the motion to receive the report; but there is no doubt that Convocation will have to be specially convened to consider so important a question. The chief resolutions on the agenda relate to the initiation of local examinations by the University. The election of graduates to serve on the Annual Committee will take place at this meeting.

THE SANITARY CONDITION OF CLERKENWELL.

AT a meeting of the Clerkenwell vestry last week orders were given for the removal of twenty-five Greek gipsies who had gained admission into a small house in the parish, which the medical officer of health stated had long since been condemned as unfit for human habitation. It may well be asked how such a house, which we presume has been reported under Torrens' Act, has for a long time remained in this condition. The vestry have ample powers to cause the demolition or repair of such premises, and the neglect to utilise them is a distinct reflection upon their sanitary administration. A member of the vestry present at the meeting drew attention to the generally bad condition of the courts of the parish, as being small, ill-lighted, and ill-ventilated, whilst the houses were dilapidated, with inefficient water and other sanitary appliances; he stated that he thought all the courts should be abolished. The medical officer added that there were twenty-six courts that should be condemned, while another vestryman expressed the opinion that all the courts of the parish were a disgrace. The Mansion House Council would be doing good service if they were to ascertain the dates at which these courts have been reported by the medical officer, and the steps which have been taken since. It is now nearly two years since this parish was the subject of inquiry by a commissioner appointed by the Home Secretary, and it would be interesting to know if his report contains the information which is wanted, and which would be useful to those who desire to see the sanitary condition of London improved.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. W. Hack, Professor of Laryngology and Dermatology in the University of Freiburg in Baden, was last week found dead, apparently from heart disease, upon his tricycle, which was standing still in the middle of the road near Staufen in the Untermunsterthal.—Dr. Max Geminger, Conservator of the Munich Zoological Museum, and a well-known entomologist.—Dr. Joseph Lerch, Extraordinary Professor of Zoology and Director of the Zoo-chemical Institute in the German University of Prague.—Dr. Vladimir T. Hörschelmann, Privy Councillor, and late holder of a high position in the St. Petersburg district, Military Medical Staff. At the time of the Crimean war he was senior surgeon of the Preobrashenski Regiment.—Dr. Edward Meyer, who is described as the Nestor of Livonian practitioners, being at the time of his death eighty-two years of age, and having taken the M.D. degree at Dorpat in 1827.—Dr. Hellinger, one of the oldest and most respected medical officials in the Rhine provinces.

PARALYSIS OF THE SENSE OF TASTE.

MANY observations point to the conclusion that any function of the living body may be annulled by the action of some specific agent. The selective action of drugs is one scientific reason for their employment in the rational and the empiric treatment of disease. Some arguments could be found to sustain the hypothesis that the treatment of symptoms is a real way of treating the disease, that suppression of all symptoms by the employment of various agents would be equivalent to the suppression of the causes of the disease. Doubtless this might hold good in some cases, but probably not in all, and the present state of knowledge gives us no warrant for asserting anything absolute on the matter. It is known that the leaf of Gymnema sylvestre, an asclepiad, has the property of abolishing the functions of tasting bitter and sweet things, of paralysing certain fibres or nerve endings of the gustatory nerves; for there is much evidence leading to the belief that there exist different sets of fibres subserving the various sensory functions, not only in the sphere of taste, but in the department of any other general or special sense.

POISONOUS BISCUITS.

Two children were recently successfully treated at the Melbourne Hospital for symptoms of poisoning, and from inquiries which were made it was supposed that their illness arose through eating some biscuits, the colouring matter of which was of a poisonous character. Similar biscuits to those which the children had eaten were obtained and forwarded to the Government analyst for report. The analysis showed that the green colouring matter on the biscuits submitted for examination was arseniate of copper. By the direction of the President of the Central Board of Health, the police in the various suburbs visited without delay the various establishments where biscuits are sold, and seized all tins containing any biscuits with green colouring matter on them. In all, over eighty tins were confiscated, and by the praiseworthy promptitude of the authorities a fertile source of danger to the infant population of the colony has been removed.

MEDICATED WINES.

WE think the Board of Inland revenue are right to place some restriction on the sale of medicated wines. Many of these preparations consist of ordinary foreign wine, often Marsala or sherry, to which some medicinal substance has been added. It is to be feared that in some cases they have been used in undue quantities for the sake of their alcohol, while in others the consumers have not known that they were drinking strong wine. In future a wine licence will be required by every person who sells them.

THE TREATMENT OF MORPHINOMANIA.

WE have recently received two publications on the treatment of this important and increasingly prevalent complaint. The first, by Dr. Oscar Jennings of Paris, is "Sur un Nouveau Mode du Traitement de la Morphinomanie," and is illustrated by nearly thirty sphygmographic tracings. The other and smaller work, covering much the same ground, is entitled "Considérations sur la Traitement de la Morphinomanie," and has been prepared by Dr. Jennings in conjunction with Professor Benjamin Ball, the well-known alienist. The drugs chiefly relied on for the cure of these patients are nitro-glycerine and sulphate of sparteine. The former is given in tabloids or as a 1 per cent. alcoholic solution, whilst the latter is administered hypodermically usually in doses of from two to four centigrammes. Sparteine has hitherto been but little used in medicine, but its action on the cardiac inhibitory ganglia is so marked that

Digitized by Google

it seems not improbable that it has a brilliant future before it. The effects on the pulse are admirably illustrated by the sphygmographic tracings, and the success attending the new method of treatment is especially gratifying.

TEA AMBLYOPIA.

WE read in a contemporary that M. Molchanoff, a Russian, who is reputed to be the wealthiest tea merchant in the world, has arrived at Paris from Hankoy with the intention of placing himself under the treatment of Dr. Charcot and an experienced French ophthalmic surgeon. The great tea magnate is suffering from amblyopia, which, it is said, is the result of the prolonged practice of tea-tasting. It is not unlikely that tea taken in excess might produce amblyopia similar in character to those toxic amauroses which result from the abuse of alcohol, tobacco, opium, and quinine; but we are not aware that this form of amblyopia has been particularly described. Wecker does not mention it in the last volume of his large work just completed, and it is not mentioned in the Real Encyclopedie, nor in the Gräfe Sämisch Handbuch. Tea is hardly indulged in in this country to a sufficient extent to produce any marked effects upon the nervous system, but it is undoubtedly a sedative and acts powerfully upon the heart.

THE HEALTH OF THE HOME SECRETARY.

WE learn that the absence from the House of the Right Hon. H. Matthews has been caused by his suffering from slight ulceration of the cornea of one eye, which necessitates some temporary rest, but involves no serious consequences. He is under the care of Mr. Brudenell Carter.

FOREIGN UNIVERSITY INTELLIGENCE.

Brussels. — The students have presented M. Ernest Rousseau, the pro-Rector, with his bust.

Cracow.—Dr. Anton Rosner, Extraordinary Professor, has been elevated to the position of Ordinary Professor of Dermatology and Syphilis.

Giessen.—Professor Schwarz is expected to succeed Professor Kaltenbach, who has gone to Halle.

Königsberg.—Dr. A. Vossius has been appointed Extraordinary Professor.

Munich.—Professor Gietl is resigning his hospital appointment, after fifty years of service.

Trieste.—The local legislative body has commenced to take steps for the establishment of a university in which Italian will be the language in which instruction is to be given.

THE efforts which are being made by the authorities with the view of stamping out rabies among the deer in Richmond Park have not produced the results which were anticipated. On the 4th inst., the official veterinary inspector reported at the Richmond Petty Sessions the slaughter of six more animals since the last sitting of the bench. Of 1500 deer in the Park over 130 have now been killed, and it is expected that many more will have to be slaughtered before the epidemic comes to an end.

MR. J. S. MORGAN has withdrawn the condition attached to his promise of £10,000 in aid of the funds of Guy's Hospital, and has made it an absolute gift. The fund now amounts to £72,000.

A VIENNA firm has received a telegram from Buenos Ayres, stating that cholera has broken out afresh there. There have been, it is reported, twelve cases in Tucuman, in the interior, and several in the city of Buenos Ayres itself.

WE understand that Messrs. Henderson Bros., managing owners of the Anchor Line of steamships from Glasgow to New York, have decided to offer to members of the medical profession desirous of attending the International Medical Congress to assemble at Washington in September next return tickets to New York for £20, giving the best accommodation at this low rate.

MR. C. R. THOMPSON of Westerham, Kent, was thrown out of his carriage on the 28th ult., and sustained such injuries that he died on the 29th, never having recovered consciousness. At an inquest held on the 30th the jury returned a verdict to the effect that death was due to a fracture of the base of the skull and concussion of the brain.

WE regret to record the death at Chenawan, in the Punjaub, of Dr. G. J. Shand, of the Indian Medical Service. The deceased entered the service in 1881, and at the time of his death, which occurred on the 1st ult. from typhus fever, held the appointment of superintendent of the Chenawan Central Gaol.

PROFESSOR VICTOR HORSLEY, F.R.S., will read a paper "On the Operation of Trephining during the Neolithic Period in Europe, and on the probable method and object of its performance," at the Anthropological Institute, 3, Hanover-square, on Tuesday, May 10th, at 8.30 P.M.

MR. H. R. BARRAUD of Oxford-street has submitted to us an excellent cabinet photograph of the late Dr. Alfred Meadows.

DR. HUGHLINGS JACKSON has received the honorary degree of LL.D. Glasgow.

ABSTRACT OF

LECTURES ON MALARIAL FEVERS.[1]

BY W. NORTH, B.A., F.C.S.,
LATE RESEARCH SCHOLAR OF THE GROCERS' COMPANY.

LECTURE II.

LOCAL CONDITIONS AFFECTING THEIR DISTRIBUTION AS STUDIED IN THE PROVINCE OF ROME.

IN the previous lecture the general relations of malaria to latitude, altitude, water, and climate have been shown to hold good for a continent, for an individual country, and for a province of that country. It remains to show how far they hold good for much smaller areas. This involves consideration in detail of localities, and with regard to each the following points demand especial attention:—1. Local conformation of the soil. 2. Constitution of the soil. 3. Water. 4. Altitude. 5. Cultivation. 6. Population. 7. Drinking-water. 8. Meteorology.

Local conformation of the soil.—The peculiar nature of the Roman Campagna, and the fact that it is by no means a plain in the generally accepted sense of the word, may be illustrated by the following examples. The neighbourhood of the Isola Farnese is exceedingly broken up by streams running in valleys with almost precipitous walls, often fifty metres and more in height. Of more undulating country, but still very broken, the neighbourhood of Tre Fontane, to the south of Rome, affords a good example. Here there are valleys whose bottoms are not more than from 12 to 16 metres, and whose sides may rise to 50 or even 60 metres above sea level. The streams which flow through these valleys are, for reasons to be considered later, liable to frequent flood, and deposit an enormous amount of mud and silt. Of true plain, the valley of the Tiber, the Pontine

[1] Delivered at the London Institution, April 25th, 1887.

Digitized by Google

region, and the low land on the coast line may be cited as the best examples.

Constitution of the soil.—It has been shown repeatedly that geology has little to do with malaria, except in so far as it affects the physical nature of the soil. The fact that the greater part of the Roman Campagna is volcanic is of material importance to the subject, inasmuch as it has a great influence on the distribution of the water underlying the surface soil. There is frequently an almost impervious layer of lithoid tufa, full of saucer-like depressions, which hold water and render the soil with which they are filled and hidden wet and boggy. In some cases these depressions are crater-like and of large size, having once been, to all appearance, volcanic lakes. These larger depressions are found chiefly round the base of the extinct volcanoes of Albano and Bracciano. The best example, perhaps, is that of the Val d'Ariccia, below Albano, which is nearly a mile across, exceedingly fertile, and very unhealthy. After heavy rain the whole valley becomes a bog, there being apparently no adequate means of escape for the water. This valley is known to have been a lake, and to have been drained in order that the alluvium which almost filled it might be cultivated. The volcanic soil holds water like a sponge, and only when it is saturated does the water issue from the hill-sides as springs, and then chiefly because it has met a layer of hard tufa which stops its downward course. Good examples of this are to be seen near Tre Fontane. Some idea of the water-holding capacity of this volcanic soil may be gathered from the following facts. In 1876 the water in the torrents in the district of Velletri began to show an increase about Oct. 20th. The total amount of water which had fallen over the drainage area since the first rains of September was equal to a depth of 25 centimetres, and represented a total of 34,000,000 cubic metres of water. In 1877 the flow did not begin till even later—viz., in the first fortnight of November, after a rainfall of 17 centimetres or a total volume of 23,000,000 cubic metres of water. The Travertine area below Tivoli is very interesting as an example of an exceedingly malarious district covered to a varying depth with a calcareous stone excellent for building purposes, and on the top of which the soil is often so thin as to render cultivation impossible.

Altitude.—The general fact that malaria diminishes and finally disappears as we ascend is undisputed. The remarkable fact about it is that a very small elevation above a malarious soil affords a very efficient protection to the inhabitants. The practice in such countries of building the houses on poles, on the tops of tombs, and similar places, is evidence of this; but it would also appear that there is an undoubted difference, as far as the risk of acquiring the disease is concerned, between a house at the bottom of one of the valleys already described and one built on the top of the hills which bound them—a difference in altitude often not more than thirty metres. The neighbourhood of the Basilica of San Paolo fuori le mura, to the south of Rome, affords a very curious example of this.

Cultivation.—The ancient cultivation and the present state of the Roman Campagna have been already discussed. The relation of malaria to trees is of great interest, though but little understood. The case of Cisterna will serve as an illustration. In 1714 it was proposed to cut down a large area of macchia which lay between the town of Cisterna and the Pontine marshes. Lancisi, the Papal sanitary adviser at the time, resisted it, and successfully, on the ground that these trees opposed a barrier or filter to the malarial emanations from the Pontine region, this idea constituting what is known as the *prejudizio palustre*. Cisterna at the time was very unhealthy, and had a rapidly diminishing population. About a hundred years later these woods were cut down, and since that time the health of the place has improved and the population almost trebled. The attempts made at Tre Fontane to improve the locality by planting eucalypti hardly admit of discussion. The plantations are too young and too small to enable any decided opinion to be formed; still, there is considerable evidence that good has been done. It may be stated generally that the effect of plantations well kept and of suitable trees is to drain the soil and distribute the water, whilst the macchia before mentioned near Cisterna, consisting of stunted brushwood, undrained and boggy, was rather a means of collecting stagnant water near the town, and its removal exposed the soil to the light and air, and so without artificial drainage what was practically a bog was got rid of.

Population.—The condition of the moving population of the Roman Campagna is a very serious question. They are ill fed, ill clothed, and worse housed, and generally are placed in circumstances which render successful resistance to the violence of the climate almost an impossibility. Density of population undoubtedly drives away malaria, and we need go no further than Rome itself for a conclusive example. Since the entry of the Italians in 1870 the city has extended enormously, and parts which at that time were something more than unhealthy are now built over and fast becoming the fashionable quarter. The areas within the walls, particularly on the south, near the Porta San Sebastiano, which are still unbuilt on, have a very evil reputation.

Drinking-water.—Is the malarial infection capable of being carried by water? This is a question which is naturally of the very first importance. The evidence, such as it is, would seem to point to an emphatic negative as the answer. The healthiest parts of the city of Rome are supplied with water admittedly the best in the world, and which rises—to take the Acqua di Trevi or Acqua Vergine as an example—on unenclosed land in springs, which bubble up and cover the surface in a locality so unhealthy that to pass several nights there in August might involve risk to life, and certainly to health. There seems to be but little doubt that a supply of good drinking-water is of importance in malarious localities, but it has yet to be shown that in exchanging pond and ditch water for that of springs the inhabitants cease to take a poison into their bodies. The evidence rather points to the fact that by so doing they raise their general health and so become less liable to the disease. At all events, proof that the malarial infection can be conveyed by water is wanting, though very largely credited by the natives of countries where the disease prevails.

Meteorology will be considered in the next lecture in connexion with the circumstances under which the disease is acquired.

It may be concluded from the above facts, and numberless similar ones which might be quoted did space permit, that the malarial infection is neither wind nor water borne, that it is extraordinarily local and dependent upon local conditions for its intensity to an extent not readily believed, and that the conditions which appear to favour its development are precisely those which affect local climate.

Pharmacology and Therapeutics.

METHYLAL.

METHYLAL, which was last year investigated from a physiological and therapeutical point of view by Personali (see THE LANCET, Nov. 6th, 1886), has since been experimented upon by Nicot, and more recently by two Russian physicians—Professor V. K. Anrep and Dr. M. Motrokhin. The results obtained by the latter of these observers are described in a "preliminary communication" in the *Vrach*. In frogs hypodermic injections of from 0·2 per cent. to 0·3 per cent. of the animal's weight produced more or less profound anæsthesia, which, however, quickly passed away. The lethal dose for frogs was found to be 0·8 gramme. Reflexes were weakened, and with large doses temporarily abolished. Thus, after giving a frog 0·3 gramme of methylal, irritation of the central end of the sciatic nerve during the period of complete narcosis produced no effect, but when the animal was aroused some reflex activity returned. Irritation of the peripheral extremity of the nerve showed that the drug had produced no effect upon its reflex action. Warm-blooded animals are more susceptible to the effects of methylal than frogs, a quantity equal to 0·25 per cent. of a rabbit's weight throwing it into a deep sleep lasting from one to two hours; with larger doses, loss of coördination in the movements was first observed, then the animal fell on its side, and remained in a state of narcosis for from three to four hours, after which it quickly recovered. The lethal dose was 0·45 or 0·5 per cent. of the animal's weight. The irritability of the cortex of the cerebral hemispheres was lowered both by hypodermic injections and by the inhalation of the vapour. Convulsions due to strychnine and picrotoxine in animals subjected to the action of a moderate dose of methylal were diminished in violence, but when the strychnine or picrotoxine was given in lethal doses death was actually accelerated by methylal. Methylal

Digitized by Google

an be employed in the form of vapour for inhalation, r as a liquid for internal administration. When given ypodermically in an aqueous solution of the strength of in 3, it is very painful, and the skin is apt to slough near he puncture. Dr. Motrokhin does not think methylal is ikely to be of use in poisoning by strychnine and picro-oxine, except when only small quantities of these poisons ave been introduced into the system. Regarding inhalations, wo ounces may be inhaled, and only produce in addition to næsthesia slight headache and dizziness. No experiments eem to have been made with a view to ascertaining the alue of methylal as a surgical anæsthetic, but it does not eem to affect the heart's action perceptibly. Prof. Anrep oticed especially that the anæsthesia was more marked on he upper part of the body.

FLUID EXTRACT OF VERATRUM VIRIDE.

Dr. N. Chistovich, chief of Professor Botkin's clinic in St. Petersburg, has just published an elaborate research on the physiological and therapeutical properties of the fluid extract of veratrum viride root. He found that in warm-blooded animals the cardiac contractions were at first distinctly diminished, but subsequently they were accelerated, the primary slowing of the pulse depending chiefly on the action of the drug on the centres of the vagus, causing an increase in the irritability of its peripheral extremities. The action on the inhibitory cardiac apparatus was manifested when the accelerator nerves and the sympathetics of the vagi were divided. The secondary acceleration of the pulse was due to a paralysing effect on the central and peripheral cardiac inhibitory apparatus, as well as to a stimulating action on the central and peripheral accelerator apparatus, this stimulation being partly accounted for by the direct action of the drug and partly by the rise of arterial pressure, which was itself due both to the increased force of the cardiac beats and to contraction of the small arteries. The number of clinical observations was much smaller than those conducted in the laboratory. The doses given were usually from ten to twenty drops of the 1 per cent. liquid extract. The cases which were found to be benefited by this treatment were those of cardiac disease when compensatory hypertrophy had not been established. In these there was almost immediate improvement in the dyspnœa and anasarca, the secretion of urine augmenting considerably and the patients feeling a great deal better. In two cases where the cardiac disease was complicated by nephritis and in one where there was pleurisy with effusion the veratrum did not seem to produce any satisfactory improvement, but it was only tried for a very short time, and no attempt was made to increase the doses.

SULPHATE OF SPARTEINE.

M. Masius of Brussels, having been engaged in investigating the physiological effects of sulphate of sparteine, has come to the following conclusions:—1. In small doses it does not modify the carotid pulsations in dogs. 2. In moderate doses it diminishes the irritability of the pneumogastric, accelerates the pulsations, which decrease in amplitude, and at the same time suppresses the periodical respiratory variations. 3. In poisonous doses it induces paralysis of the pneumogastric, also asphyxia, and, as a consequence of asphyxia, a change in the pulsations, which become larger and less rapid, and then quickly smaller and smaller, till they take on the characters of "alternate pulse," and finally cease. 4. The blood pressure decreases only a short time before death. 5. It exerts in the healthy subject no effect on the urinary secretion. 6. In disease its effect on the heart is uncertain, as well as its effects on the urinary function and on the subjective condition of the patient.

COMMON SALT IN MIGRAINE.

Dr. Rabow, of Berlin, finds that half a teaspoonful or more of common salt, taken as soon as the premonitory symptoms of an attack of migraine begin to show themselves, will frequently cut it short in about half an hour; similar treatment has also proved of service in epilepsy, as was remarked some years ago by Nothnagel: the explanation being probably in both cases that a violent reflex action is set up.

ON the 9th inst. an afternoon concert, conducted by Mr. Henry Leslie, will take place at Grosvenor House, by the permission of the Duke of Westminster, in aid of the funds of the Hospital for Women, Soho-square.

THE ROYAL ACADEMY OF ARTS.

IT is significant of the wealth of artistic talent in this country that, although the present exhibition contains no works by such masters of the craft as Watts, Vicat Cole, Burne Jones, Calderon, Poynter, G. Richmond, and Woolner, it is nevertheless one of extraordinary merit and interest. It would seem as though the financial depression, which is naturally felt most keenly by the sensitive profession of Art—a profession which is an appendage of the luxuries, not the necessities, of life,—has incidentally served to stimulate the energies of the painters to exertion, which were not displayed, because possibly they were unnecessary, in the piping days of commercial prosperity which prevailed some fifteen to ten years since. Notwithstanding that we have passed through—if we have passed it—a winter of exceptional cheerlessness and want of light, the keen competition which the present position of Art in England renders necessary has served to produce an exhibition abounding in works of merit. Our readers will find no small recreation in a visit to this, the most popular of all the exhibitions of the metropolis.

From a purely medical and professional standpoint, we have not so much to point out as in many former years. There are perhaps fewer than usual great notabilities of our ranks who are immortalised on canvas or in marble, and incidents of the works calling for criticism from the anatomical or physiological side do not appear to be numerous. We may, by the way, remark that there is a picture of extraordinary power by S. J. Solomon called "Nature," No. 503, Gallery No. 7., that should not on any account be missed. It is a huge canvas, and the story of the hero when dispossessed of his locks by the crafty Delilah falling a victim to the bonds of the Philistines is admirably told—so admirably, that it may appear captious to point out that the Philistine in front, whose leg is half-flexed upon the thigh, would not in this position have the vasti muscles (the extensors of the leg) standing out prominent and rigidly contracted. It is not so very uncommon to find that painters who have studied the muscular system have failed to seize a correct idea of the conditions under which the muscles are contracted or relaxed, and, in their anxiety to give as much anatomy as they can, portray a contraction where it should not be found.

Amongst the portraits of medical interest is that of Dr. Walter Fergus, by Wirgman, and Sir Rutherford Alcock, K.C.B., by Arthur J. Foster. This latter, although placed too high to be perfectly examined, is conspicuous by its truth and power; it is an admirable likeness, and we would especially note the dexterity and, at the same time, the conscientiousness of the painter in his treatment of the sitter's hands. A landscape by the same painter hung on the line in Gallery No. 8, called "A Harbour at Low Tide," is an admirable bit of seaside painting, and a proof of the artist's versatility. Mr. Luke Fildes strikes new ground in two portraits of great power; and Mr. Sargent's portrait of Mrs. William Playfair will interest especially those possessed of artistic sensibility. In Gallery No. 4 Surgeon-General Maclean looks down upon us with his well-known amiable physiognomy; and in Gallery No. 5 we find Dr. Edward Waters immortalised by Frank Holl. In the lecture-room there are good busts of Sir Henry Acland, by J. E. Boehm, and of Dr. Cholmeley, by C. B. Birch.

THE GROSVENOR GALLERY.

The Grosvenor Gallery has been open for eleven years, and has suffered no falling off and no important defections. The President of the Royal Academy does not often contribute, and this year admirers of Mr. Alma Tadema must content themselves here with works by his wife and his daughter. Mr. Whistler has found a home of his own at the "British Artists," but most of those who have made the reputation of the Gallery are faithful to Sir Coutts Lindsay, to whom newer men also are not wanting. Portraiture and landscape are undoubtedly the strong points of English art at the present time, but it is on ideal work that the Grosvenor Gallery especially relies. This year Mr. Watts sends a "Judgment of Paris," a vision of the three goddesses bathed in a glory of light, which he has never surpassed. Perseus shows to Andromeda the reflection of the head of Medusa in Mr. Burne Jones's chief picture, the

Digitized by Google

other being a landscape with three figures—the garden of Pan. Both are mediævally conceived and treated, but in landscape this is surely a retrogression, while the mystical truth of the old Greek legend is finely presented, with delicate colour and consummate drawing. Mr. W. Richmond's Fiammetta is a beautiful ideal study of a girl, much influenced by Leonardo and the Lombard School. Mr. Hacker, however, has produced the picture which will probably draw most attention, as the striking work of a rising artist—"Philammon watching Pelagia asleep in the Desert," from C. Kingsley's "Hypatia," a book which furnished Mr. Mitchell with the subject for a painting which made a sensation here two years ago. The large work by the last-named painter in the east gallery, of the "Resurrection of a Saint at the Crucifixion," shows a great falling off, except in the fine figure of the mother. In landscape the exhibition is not very strong, but we must mention the "Loch Awe" of Mr. Keeley Halswelle, the works of Mr. Alfred Parsons and Mr. J. W. North, the sea of Mr. Henry Moore, and the sea *genre* pieces of Messrs. Bartlett and Napier Henry. But in portraits there is full compensation. Mr. Frank Holl sends three, notably one of Lord Harlech; Mr. Herkomer also three, of which that of the late Professor Fawcett is the best; Sir John Millais two, one of his daughter, the other of Lord Esher, Master of the Rolls, in his robes, the latter being especially warm and harmonious. Mr. Burne Jones's finest work is the portrait of a lady in blue, seated with her back to a convex mirror, in which the influence of the late D. G. Rossetti is very strong; the subdued power and beautiful execution of this picture will appeal to many to whom the painter's allegories are unintelligible. Mr. W. B. Richmond contributes four portraits of both sexes and various ages, in his refined eclectic style and rich colour. Of less known artists, we would draw attention to Mr. W. Carter's picture of Mrs. C. A. Fyffe.

WATER COLOURS.

The Royal Institute of Painters in Water Colours has filled its rooms with pictures to the ceiling, but has not made a very interesting exhibition in consequence. Several leading members send no contributions, but the best work belongs, nevertheless, to old members, who do not depart from their established lines. There is plenty of work of a high quality, though nothing of exceptional originality or importance. The third room is perhaps rendered the most striking by Mr. Langley's "Betrayed," and "The Miser's Death," by Mr. Joseph Nash.

THE ART JOKE.

Mr. Harry Furniss, the versatile and amusing artist so well known in the pages of *Punch*, has opened a "Royal Academy" of his own at the Gainsborough Gallery, 25, Old Bond-street. This consists of a room full of large monochrome drawings, burlesquing the mannerisms of the leading artists and the artistic fashions of the day, not without some cuts at the Academy itself, and popularity-hunting and "pot-boiling." We have no space to mention more than the severely close rendering of "Cinderella," and the humour of the "Modern Lady Godiva," which disposes of the question of the prude and the nude. Altogether the exhibition must delight everyone who knows the originals, and can do no harm even to its victims.

SANITARY REGISTRATION OF BUILDINGS.—On the 2nd inst. the second meeting of the Conference convened by the Council of the Sanitary Assurance Association was held for the purpose of considering the details of the Sanitary Registration of Buildings Bill (down for second reading on the 22nd prox.), the principle having been assented to at the first sitting. Sir Joseph Fayrer, M.D., presided. The bodies represented, besides the Sanitary Assurance Association, were the Royal Institute of British Architects, Public Health Medical Society, London Sanitary Protection Association of Municipal and Sanitary Engineers and Surveyors, and Royal Institute of Architects of Ireland. The exclusion of places of less than 2000 population from the Bill was amended by the insertion of a declaration that the Act should next year apply throughout the United Kingdom. A proposal to make the measure compulsory on all buildings was rejected. The further consideration of the matter was deferred for a fortnight.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kendal Urban District.—Mr. Charles E. Paget records the death-rate of this borough during 1886 as 16·5 per 1000—namely, 2·4 less than the mean for the quinquennium 1881-85, and it is held that this satisfactory result has been greatly brought about by the influence of the borough sanitorium in controlling the spread of infectious diseases. In 1884 the authority saw the advisability of erecting a second ward-pavilion, and on two occasions during the present year the coexistence of two separate diseases needing hospital isolation has shown the wisdom of this course. Interesting details are given as to several branches of the sanitary work carried out; and it is noted that the defective sewer ventilation which, associated with a curious combination of meteorological circumstances, led to an outbreak of enteric fever in the early part of 1884, has been largely remedied, some sixty to seventy new ventilators having been put in. But Mr. Paget gives cautionary advice as to the need for constant watchfulness for evidences of such over-pressure of sewer air as calls for legitimate relief through ventilators in all extensions of borough sewers.

Hanley Urban District.—The mortality of infants under one year of age has for the past four years averaged some 19·9 per cent. of the births registered. In 1886 it was at that rate, whereas the corresponding rate for the twenty-eight large English towns did not exceed 16·9 per cent. Neglect of infants by exposing them to cold, improper feeding, and the use of narcotics and other deleterious drugs are, in the opinion of Dr. S. Walker, responsible for this needless waste of infant life—a waste which is unfortunately on the increase. In some towns Ladies' Associations have—as, for example, by the aid of the tracts issued by the National Health Society—succeeded in educating their fellow towns-women as to the proper precautions to be taken with infants, and some such work would not be out of place in Hanley. In regard of phthisis, it is most satisfactory to note how steadily the death-rate from this disease has become reduced since the completion of the sewerage system, until it stands at 1·4 per 1000, as opposed to 2·0 in London. The report, which deals mainly with statistics and actual causes of disease, does not point out the sanitary advice given, or the work needed in the future, or the circumstances under which the people are living, and which tend to affect health. But the inspector of nuisances supplies a table of current nuisances dealt with.

Newcastle-upon-Tyne Urban District.—Mr. Henry Armstrong's annual report for 1886 shows that the general mortality was at the rate of 22·2 per 1000. Under the Improvement Act of 1882, 1348 cases of infectious diseases were notified, and of these 1004 were scarlet fever, 205 enteric fever, and 73 diphtheria; the report sets forth in detail the circumstances under which the diseases occurred and the remedial measures adopted. Amongst the latter we find that in 108 cases removal to either the fever or the small-pox hospitals was effected, and in 19 cases orders of justices were obtained as to burial of corpses. The construction of new dwellings during 1886 has made provision for 1158 families, at the rate of 5 persons to a family; and plans for 837 new dwellings, of which 638 consisted of flats, were examined by the medical officer of health. Amongst the details of sanitary work carried out, we find that the bakehouses, dairies, cowsheds, milk-shops, and slaughter-houses have been inspected, and that the licensing of the latter is not granted except after such works as tend to ensure wholesome conditions for the storage of human food.

Aylesbury Rural District.—Dr. Hilliard takes occasion in his annual report for 1886 to point out how, on several occasions, early information as to occurrences of measles and scarlatina has enabled him to prevent the spread of those diseases. In some parts of the district the continuance of defective sanitary conditions shows itself by outbreaks of preventable disease. Thus, in the village of Westcott, which is of all others worst off for water, there were twelve fatal cases of diarrhœa; and at Aston Clinton, where faults of water still prevail, typhoid fever continues

Digitized by Google

recur. The death-rate for the district was 18·6 per 000. A good deal of current sanitary work is carried out, he notices relating to such work numbering many hundreds nder several separate headings.

Tunbridge Wells Urban District.—During 1882-86 the ean death-rate for this district was only 15·1 per 1000 per nnum, and in 1886 it was 14·4. The only noticeable mor-ality was that of nine infants from diarrhœal affections, nd Mr. Wm. Stamford is induced to attribute this mainly o fermentative or putrefactive changes in the milk with vhich infants are fed. Some scarlatina was checked by the se of the infectious hospital provided by the sanitary uthority; and amongst a good record of sanitary work arried out during the year we note that the water-service vas laid on to 142 houses.

Eccleshill Urban District.—Measles has been very preva-ent in this district, and this, together with some diphtheria nd diarrhœa, raised the death-rate for 1886 to 17 per 1000. Measles was found to be difficult of control, especially on account of many of the attacks being so mild that no medical attendance was sought. Hence Dr. Byles only eard of the cases when serious complications supervened.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5816 births and 3647 deaths were registered during the week ending April 30th. The annual rate of mortality in these towns, which had been 20·5, 20·9, and 21·6 per 1000 in the preceding three weeks, declined again last week to 20·6. During the first four weeks of the current quarter the death-rate in these towns averaged 20·9 per 1000, and was 2·5 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 10·5 in Derby, 14·6 in Brighton, 15·7 in Leicester, 16·3 in Portsmouth, and 16·3 in Bradford. The rates in the other towns ranged upwards to 28·2 in Bristol, 30·8 in Blackburn, 31·3 in Huddersfield, and 35·4 in Cardiff. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had steadily increased in the eleven preceding weeks from 340 to 558, declined again last week to 529; they included 261 from measles, 132 from whooping-cough, 51 from scarlet fever, 43 from diarrhœa, 25 from diphtheria, 15 from "fever" (principally enteric), and only 2 from small-pox. No death from any of these zymotic diseases was registered during the week in Preston, whereas they caused the highest death-rates in Sheffield, Norwich, and Oldham. The greatest mortality from measles occurred in Manchester, Sheffield, Sunderland, Liverpool, Salford, Oldham, and Norwich; from whooping-cough in Newcastle-upon-Tyne, Cardiff, and Blackburn; and from scarlet fever in Blackburn, Sheffield, and Oldham. The 25 deaths from diphtheria in the twenty-eight towns included 16 in London and 5 in Liverpool. Small-pox caused 1 death in Sheffield and 1 in Cardiff, but not one in Greater London or in any of the twenty-five other large provincial towns. Only 6 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; no new case was admitted to these hospitals during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding five weeks, from 509 to 337, were last week 338, and 49 below the corrected average. The causes of 75, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Portsmouth, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Sunderland, Leicester, Preston, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·7 and 22·0 per 1000 in the preceding two weeks, rose again to 22·5 in the week ending April 30th; this rate exceeded by 1·9 the mean rate in the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 9·7 and 15·1 in Perth and Leith, to 24·8 in Glasgow and 26·5 in Paisley. The 563 deaths in the eight towns last week showed an increase of 13 upon the number in the previous week, and included 36 which were referred to whooping-cough, 27 to measles, 8 to scarlet fever, 8 to diarrhœa, 6 to diphtheria, 4 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 89 deaths resulted from these principal zymotic diseases, against 91 and 95 in the preceding two weeks. These 89 deaths were equal to an annual rate of 3·6 per 1000, which exceeded by 0·6 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 36 in each of the previous two weeks, were again 36 last week, of which 16 occurred in Glasgow, 7 in Edinburgh, and 6 in Dundee. The 28 deaths from measles were within 3 of the number in the previous week, and included 13 in Aberdeen, 12 in Glasgow, and 2 in Greenock. The 8 fatal cases of scarlet fever showed a further slight decline from recent weekly numbers; 4 occurred in Edinburgh and 2 in Greenock. Of the 8 deaths attributed to diarrhœa, 3 were returned in Dundee and 2 in Edinburgh. Four of the 6 fatal cases of diphtheria, and 2 of the 4 from "fever," occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 126 and 124 in the preceding two weeks, further declined last week to 111, and were 12 below the number in the corresponding week of last year. The causes of 70, or more than 12 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 30·0 34·1, and 31·3 per 1000 in the preceding three weeks, was again 31·3 in the week ending April 30th. During the first four weeks of the current quarter the death-rate in the city averaged 32·2 per 1000, the mean rate during the same period being but 18·6 in London and 19·5 in Edinburgh. The 212 deaths in Dublin last week corresponded with the number returned in the preceding week; they included 11 which were referred to measles, 4 to whooping-cough, 3 to "fever" (typhus, enteric, or simple), 3 to diarrhœa, 2 to diphtheria, 1 to scarlet fever, and not one to small-pox. Thus 24 deaths resulted from these principal zymotic diseases, against 22 and 19 in the preceding two weeks; they were equal to an annual rate of 3·5 per 1000, the rates from the same diseases being 2·6 both in London and in Edinburgh. The 11 fatal cases of measles showed a further considerable increase upon recent weekly numbers, while the deaths from the other zymotic diseases did not show any material variations. The deaths both of infants and of elderly persons showed an increase upon those returned in the previous week, while those of persons aged between one and sixty years had declined. Five inquest cases and 5 deaths from violence were registered; and 50, or more than a quarter, of the deaths occurred in public institutions. The causes of 34, or more than 16 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major William James Wilson, M.D., to be Brigade Surgeon, vice William Cherry, granted retired pay (dated March 28th, 1887); Surgeon-Major John Croker is granted retired pay (dated April 30th, 1887).

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the following Officers of the Indian Military Forces:—Brigade Surgeon Henry Cayley, of the Bengal Medical Establishment (dated April 29th, 1887); Brigade Surgeon Cameron Joseph Francis MacDowall, of the Bombay Medical Establishment (dated April 1st, 1887); Brigade Surgeon Henri Jules Blanc, M.D., of the Bombay Medical Establishment (dated April 2nd, 1887); Surgeon-Major Warwick Jackson, of the Bengal Medical Establishment (dated April 8th, 1887); and Surgeon-Major Robert Reid, of the Bengal Medical Establishment (dated April 25th, 1887).

The under-mentioned Officers have been granted a step of honorary rank on retirement:—Brigade Surgeon Cameron Joseph Francis MacDowall, of the Bombay Medical Establishment (dated April 1st, 1887), and Brigade Surgeon Henri Jules Blanc, M.D., of the Bombay Medical Establishment (dated April 2nd, 1887), to be Deputy Surgeons-General.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon Fleetwood Buckle, to the *Unicorn*;

Digitized by Google

Surgeon Hamilton E. L. Earle, to the *Duncan*, additional, for disposal; Surgeon George A. Dreaper, to the *Triton*, additional; and Surgeon Henry B. Beatty, to the *Duncan*, additional.

ARTILLERY VOLUNTEERS.—3rd Durham: Jas. Drummond, M.D., to be Acting Surgeon (dated May 4th, 1887).—1st Kent: William Lindsay Chubb, Gent., to be Acting Surgeon (dated May 4th, 1887).—1st Newcastle-on-Tyne: Surgeon R. Young, M.D., resigns his commission (dated May 4th, 1887).

RIFLE VOLUNTEERS.—2nd Ayrshire: Surgeon and Honorary Surgeon-Major R. Dobbie, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement (dated May 4th, 1887).

THE VOLUNTEER MEDICAL STAFF CORPS.—The Maidstone Division: Surgeon and Honorary Surgeon-Major David Henry Monckton, from the 2nd Volunteer Battalion, the Prince of Wales's (North Staffordshire Regiment), to be Surgeon (dated May 4th, 1887).

Correspondence.

THE PENGE CASE.

To the Editors of THE LANCET.

SIRS,—Many of your readers will recollect that about eleven years ago four persons were found guilty of murdering Harriett Staunton by starving her, and were condemned to death; but that to a large proportion of the public, and to a larger proportion of the medical profession, the evidence that was adduced did not seem to justify the verdict of the jury or the sentence of the judge; and that subsequently the prisoners' punishment was commuted to penal servitude for life, a result which was largely due to the action of THE LANCET, through whose agency a petition signed by over 700 members of the profession was presented to the Home Secretary. Shortly afterwards one of the female prisoners had a free pardon accorded to her; some five or six years ago one of the brothers Staunton died in prison of consumption; and about three years ago Sir W. Harcourt set at liberty the wife of the deceased brother. One only of the party still remains a prisoner. For my own part, I believe the accused were innocent of intentional wrong. But even granting what many of those who helped to save them from death believed that they had been guilty of gross, and even criminal, negligence, eleven years of penal servitude is a heavy and surely sufficient penalty to exact. Considering, however, that two have already been pardoned, it is certainly hard that the same grace should after so many years of punishment be withheld from the last of the number. Will you allow me to mention that a petition to the Home Secretary praying for the release of Louis Staunton is now in process of signature, and to invite some of those who signed the former memorial to attach their names to this?

I am, Sirs, yours faithfully,

Old Burlington-street W., May 4th, 1887. J. S. BRISTOWE.

THE TREATMENT OF EPISTAXIS BY COUNTER-IRRITATION OVER THE HEPATIC REGION.

To the Editors of THE LANCET.

SIRS,—I was much pleased to observe in a letter from your Paris correspondent, dated April 27th, that at a recent meeting of the Academy of Medicine M. Verneuil read a communication upon the treatment of certain forms of epistaxis by counter-irritation over the region of the liver. In the first case related by M. Verneuil, quinine, ergotine, and digitalis had all been tried in vain. In the second, plugging had failed. The third had been the subject of chronic nephritis, with secondary affections of the heart and liver, and the cavity of the nose had been plugged without effect both with ergotine and the perchloride of iron. M. Verneuil's treatment, which was immediately and permanently effective, consisted in the application over the region of the liver of a large blister. M. Verneuil had at first thought that the method was entirely his own, but from bibliographical research it turned out that it had been anticipated to a certain extent by Galen, who says that large cupping glasses applied to the hypochondriac region arrest nasal hæmorrhage. To me it is very satisfactory to learn that a mode of treatment practised by myself successfully for many years, and reported in THE LANCET of Oct. 30th, 1886, with cases in illustration, has also been advocated by so eminent an authority in continental medicine, and, as far as he was concerned, independently of any suggestion from another. I am quite sure that, in his case any more than my own, the dictum of Galen had nothing to do with its origination. It is of more importance that the remedy, which is undoubtedly of the utmost value, should be more generally adopted, especially when its application is urged not upon merely empirical grounds, but in accordance with accepted pathological teaching. That your correspondent did not appear to be aware of my previous pronouncement on the subject arose possibly from the fact that my publication did not take the form of a monograph with specific heading, but as portion of a paper treating of congestion of the liver, and protesting against the impolitic interference of modern surgery with the sanitary efforts of Nature when through the medium of hæmorrhage from the hæmorrhoidal veins or the mucous lining of the nostrils she endeavours to lessen the turgescence of an important viscus. In illustration of my views, I gave the particulars of a case of vicarious bleeding from the under lip, which arose immediately after the deligation of hæmorrhoidal tumours with excessive bleeding, ultimately cured by blistering over the liver; of a second example, in which dangerous and profuse hæmorrhage from piles was immediately cured by a similar remedy; and then, in pursuance of my theme, appended the cases of three young men suffering from epistaxis, who were instantly relieved by blistering over the hepatic region. A remarkable case, which occurred during the recent riots in Belfast will further illustrate the subject: While paying my morning visit to a straw lodge, a temporary barracks improvised for the members of the Royal Irish Constabulary, and accompanied by one of the officers, I found one of the men in bed with a handkerchief saturated with blood, which had flowed from his nose during the greater part of the previous night. On satisfying myself of the nature of the illness, I painted the man freely with the liquor epispasticus over the region of the liver, prescribing no other remedy but rest in bed. On our revisiting the man next day, he informed us that from the moment the blister began to pain him the hæmorrhage declined, and left him altogether a short time after. To quote from my paper: "The frequent occurrence of epistaxis in youth is evidently due to the excitement and hyperæmic condition of the liver and digestive organs during the period of active growth and the constant demands upon its functional activity. The liver at this stage closely approximates to the condition in after-life, which is the causal factor in the development of piles, and as such is equally amenable to treatment in accordance with etiological principles; the derivative that cures the hæmorrhoidal flux as certainly puts an end to the epistaxis, the outcome of hepatic congestion."—I am, Sirs, yours very truly,

Belfast, May, 1887. ALEXANDER HARKIN, M.D., F.R.C.S.

ON THE NECESSITY OF OBTAINING POWERS TO DETAIN IN WORKHOUSES AND INFIRMARIES PATIENTS AFFECTED WITH VENEREAL DISEASES.

To the Editors of THE LANCET.

SIRS,—A few years ago our Government, swayed by the twaddle of sentimental politicians and by a misguided and ill-informed public, had the rashness to repeal the Contagious Diseases Act, and thus has engendered the spread of venereal diseases not only amongst our sailors and soldiers, but throughout the community. I now wish to call attention to the pressing necessity of acquiring powers to detain patients suffering from these diseases in our Poor-law and other institutions until well. In some of our workhouses and infirmaries patients are found suffering from the most fearful ravages of syphilis and from the most virulent forms of gonorrhœa, and many of them insist on taking their discharge before they are cured. Now, for such patients to have it in their power to leave the infirmary or workhouse before recovery is not only most unsatisfactory as regards the treatment of them, but is simply

Digitized by Google

spreading disease broadcast, and is likewise a grave injustice to the ratepayers, upon whom is thrown the cost of their maintenance when ill. It is not my intention to discuss the merits of the Contagious Diseases Act, but I will say that its repeal, in addition to facilitating the spread of venereal diseases, has a tendency to encourage seduction and prostitution amongst a large class of girls and young women who support themselves in an honest and respectable way. It appears to me to be the duty of medical men who are members of Parliament, or otherwise possess considerable influence, to try to introduce another Contagious Diseases Bill, or, failing that, some measure giving powers for the detention of these cases in our Poor-law institutions until they can be discharged cured.

I am, Sirs, yours faithfully,

April, 1887. ARTHUR FFLINTOFF MICKLE, M.B.

TANGIER AS A HEALTH-RESORT.

(*From a Correspondent.*)

As a winter station and a pleasure resort Tangier is rapidly acquiring considerable popularity. Many circumstances combine to bring about this favourable result. Politically, the range of modern artillery has rendered Tangier a military position second only to the Suez Canal. Without attempting to discuss here all the complications that arise from the necessity of keeping open the Straits of Gibraltar and the efforts of English diplomacy to prevent any powerful nation becoming master in Morocco, it is nevertheless necessary to mention the existence of these grave political questions in order to account for the importance now attached to all that concerns the town of Tangier. Already the Sultan of Morocco has been termed "the new sick man," and it is evident to all politicians that the Eastern question is travelling westwards, and may have to be fought out in the Straits of Gibraltar as well as at the Dardanelles or the Red Sea. Conjointly with these considerations, the development of trade at Tangier has been most marked. The increase of exports and imports in 1885 was nearly equal to a third more than the average of the previous five years. Thus, either politically or commercially, Morocco is daily becoming better known. Though within three hours' sail of the high degree of civilisation prevailing at Gibraltar, Tangier still maintains primitive Oriental customs and appearance. To those who thirst for a complete change, who are tired of the ordinary resorts of the invalid or the tourist, Morocco may be confidently recommended. The need of such change is very generally recognised, especially when dealing with those nervous diseases that are more prevalent as the strain of our highly wrought civilisation becomes greater. But the health stations of the Continent grow more and more like each other; there is a wearisome sameness about the hotels, the society, and surroundings, which many would like to avoid. On the other hand, a thorough change is generally thought to involve a long journey, a sojourn in a country far removed from the resources of civilisation, where some personal risks must be incurred. Tangier, however, can be reached from London in five or six days by the Forward line of steamers, and from Marseilles in three days and a half by the Pacquet line. The overland journey to Cadiz, Malaga, or Gibraltar brings the traveller within a few hours' sail of Tangier; and, when once here, he can benefit by the wildest scenery, the most complete change, while enjoying perfect personal security. In spite of the barbarous aspect of the country, the European is safer from robbery and aggression than in the streets of London or Paris. The dread of the Moorish authorities lest any complaint made by a European should lead to an invasion of their country has brought about the application of the severest and the most cruel measures of repression. Quite recently a man was flogged to death because he was supposed to have robbed a foreigner. Others are left to die of starvation in prison when they are accused of owing money to persons under foreign protection. Whole districts have been most cruelly oppressed, taxed, and half ruined to supply compensation for some slight robbery committed in the neighbourhood. Yet all this, heinous as it is, has, on the other hand, the result of terrifying those who otherwise might be guilty of acts likely to alarm intending visitors. Thus it is possible to live without fear or risk in a country of easy access from England, and yet where there are no regular roads, no carriages, no railways, no police, no inland post, no municipalities, no rates or taxes for Europeans to pay, no standing army or drilled troops, no daily newspaper, no public opinion, where, under the capitulations, there are thirteen Christian and one Mahomedan constitutions having the force of law, and where, in spite of all this, a sufficient amount of material comfort may be enjoyed conjointly with the benefits of a most genial climate. If it is change of life, scenery, and climate that have been prescribed for the patient, it would be impossible to find nearer home anything more thorough in this respect than Tangier. Even if there were nothing else to say in its favour, this is enough in itself to show that it may render much service.

From time immemorial, however, Tangier has been renowned for its equable and salubrious climate. It was much esteemed by the ancient Romans, who built here a commercial town on the east and a military fortress on the west side of the bay. Long before their time, before Rome itself sprang into life, the exceptional position occupied by Tangier had attracted various races and tribes, and it is said that there are only two other towns in the world whose existence can be traced so far back. A glance at the map will show that Tangier is situated on a promontory running northward from the mainland of the African continent. It is nearer to the Atlantic than to the Mediterranean. The north-west, west, and south-west winds are all Atlantic winds. The north-east blows down the straits from the Mediterranean, and the east and south-east also blow from the Mediterranean over the Reaf Mountains and across the Bay of Tangier. Thus nearly all the winds that reach Tangier are sea winds, and therefore supply an atmosphere of exceptional purity. Even the north wind, which comes direct from Spain, is refreshed and purified by crossing the Straits of Gibraltar. The due south is alone a land wind, and, coming from the desert, might be extremely unpleasant. Fortunately, this wind must first pass over the eternal snow of the Atlas Mountains before it can reach Tangier. Thus even in summer the climate is comparatively cool, while in winter it is exceptionally warm. The better-known winter stations on the French or Italian Riviera receive as many land as sea winds. Those winds that do come over the water blow from the Mediterranean, and this sea does not seem to agree with English constitutions so well as the Atlantic. Again, comparing Tangier with the Riviera, it will generally be admitted that there is not the same and dangerous difference between night and day temperature. At sunset the thermometer falls much more than in England, but less than on the Riviera. Frosts are extremely rare. This winter, which has been so exceptionally cold throughout the west of Europe, brought only a few flakes of snow, that melted as soon as they touched the ground. On the other hand, Tangier is not so dry as the Riviera resorts. While the record of the thermometer is most favourable, the individual may nevertheless feel chilly because of the dampness that arises at night. Extra clothing, and perhaps a little fire in the evening during the depth of the winter, amply suffice to cope with this disadvantage; but it is essential to take this local peculiarity into account, or the patient will be unpleasantly surprised to find that his personal sensations do not harmonise with the temperature marked on his thermometer. Unfortunately, there is no regular meteorological station at Tangier. Observations have been taken here and there; the best are those of the German Legation, but these statistics are not compiled, and the summary of the results have not been made public. Dr. Arthur Leared, in his interesting work on "Morocco and the Moors," gives statistics taken in a *patio* or courtyard, showing that during the year 1872 the maximum (reached in June) did not exceed 83° F., and the minimum (attained in December) was not lower than 50° F. During the six winter months the thermometer ranged from 66° F. to 50° F. But these statistics are not sufficiently extensive to warrant the formation of any definite opinion.

Perhaps, under these circumstances, it would be safer to rely on the vegetation as the surest evidence of climatic advantages. There are, it is true, comparatively few gardens at Tangier; but if the necessary money were forthcoming almost any plant could be grown here. The tropical and semi-tropical plants to be seen on the Riviera may also be found in the neighbourhood of this town; but many of these have grown with more vigour and attained larger dimensions. This is especially the case with respect to the Egyptian and Mexican bamboos in the garden of the Belgian

Digitized by Google

Legation and the *Dracæna drago* at the German Legation. This latter tree is one of the curiosities of Tangier. It is probably more than 300 years old, and is considered the finest specimen in the world. At the Canary Islands there is one tree of this sort which is larger, but it is not so high or so handsome. Close at hand the *Datura* shrub, which is killed by 2° to 3° F. of frost, may be seen growing to a height of more than twelve feet. Wild oleanders abound in great luxuriance throughout the country. The *Belas ombré*, with its giant roots, and the *Chamærops humilis*, the date palm, grow naturally—that is, in a wild state and without cultivation. The cedars of Lebanon, the *Laurus*, both *tenus* and *nobilis*, the banana, the *Strecia*, the *Magnolia grandiflora*, and many other plants that are only known in the hot-houses of England, prosper here in the open air, even when little care is taken to preserve them. But perhaps the best illustration of the equable nature of the climate is that of the *Araucariæ excelsa;* for, while this fir can stand but little heat, it is killed at once by the frost. If the heat continued for a few days consecutively at 75° F. the leaves would turn yellow; and it is extremely difficult to find any place where this tree will grow. Yet at Tangier several specimens have been successfully reared, notably under the able surveillance of a German horticulturist, Herr Ferdinand Neureuter, who is in charge of the gardens belonging to Mr. Perdicaris.

The salubrious character of the climate is further demonstrated by the observations of medical men who have practised for some time in this country. Dr. Miguères, who has resided at Tangier some sixteen years, acting in the capacity of consulting physician to the French Embassy and to the French Hospital, and who has had a most extensive practice among the native and foreign population, declares that many diseases which in other countries last from fifteen to twenty-one days reach the convalescent state at Tangier in from ten to twelve days. This is, of course, more particularly the case with the natives or those foreigners who are thoroughly acclimatised. Among the diseases that rarely attain a malignant form may be mentioned typhoid and scarlet fever, measles, and diphtheria. Though in England there is such good reason to dread any outbreak of scarlet fever, its occurrence here is very rare, and of remarkably mild character. A fever, however, which in many respects bears a close resemblance to typhoid is of somewhat frequent occurrence. Infantile diarrhœa is also very prevalent, and one of the principal causes of mortality. It is doubtful whether the climate would be of any use in the more advanced stages of phthisis. But the results attained during the earlier development of the disease are most encouraging. These facts are confirmed by the records kept at the hospital and by the local practitioners.
